Celery.—The main crop of Celery may be earthed up, taking care to pulverise the soil before doing so, and choosing a dry day for doing the work, water being afforded the plants a few hours before beginning to earth up. If the garden be infested with slugs and snails, first afford the trenches a liberal dressing of quicklime. Celery for use in the months of October and November may now be earthed up fully, but later crops not more than half way, more than this causing the decay of the heart-leaves still low down in the plants. It is good practice to go over growing Celery twice or thrice during the season, and tie the leaves loosely together with broad strips of bast or raffa to prevent the leaves being broken by the wind.

Pests are becoming rarer, and every means should be taken to prolong the season by netting the rows so as to preserve the pods from being eaten by small birds. If mice are many, set traps for them, or these creatures will cause much loss.

Mustard and Cress will require a slight protection after this date, and the seeds are best sown in a cold frame or hand-light. When cold weather sets in, sow the seed thinly in shallow boxes, as these can be shifted about as may be desired. Do not cover the seed with soil, but simply make the soil firm, and then sow evenly on the surface, and cover with a board or slate till it sprouts.

Spring-sown Onions.—These will now be ripe, and ready for pulling, about which there should be no delay, or it may be difficult to dry the bulbs, if there are many of them. Given a few fine days, there will be no difficulty in drying them on the ground, if they are turned over daily till dried; but in wet weather it may be advisable to place them on a hard path, or on a bed of coal-ashes to dry. Onions should not be stored in heaps, but laid out thinly in an airy shed for a few weeks, the final sorting and tying into bunches, &c., being left for a wet day at a later date.

If several varieties are grown, let each be kept separate, otherwise the latest keepers may chance to be used first.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Transplanting Strawberries.—Where not already done, no time should be lost in making plantations of Strawberries. The ground for this crop should have received a heavy dressing of decayed manure, and been trenched or deeply dug. In planting, set out the plants in rows at from 20 inches to 2 feet each way, according to the strength of the variety, pressing the soil pretty firmly around the roots of the plants, but keeping the crown slightly above the ground level.

Early forced plants of Laxton's Noble, Garibaldi (syn. Vicomtesse Héricart du Thury), and Royal Sovereign, which had been duly hardened off prior to being transplanted in the open in prepared ground in spring, should have a little more clean straw placed under the clusters of fruit.

Morello Cherries.—If the fruits have been left on the trees for gathering, they should be looked over often, and the decayed fruits removed, so as to prevent decay spreading to the sound ones. The Morello Cherry is liked by some persons as a dessert fruit during the present month for its pleasant acidity; moreover, a dish of large, well-coloured Morellos is not the least of the attractions of the dessert at this time of the year.

Summer-bearing Raspberries.—The canes which have borne fruits should be cut down to the ground, so as to let in sun and air to the current season's canes; and in order to secure them against the wind, twist a length of tarred string once round lines of stoutish sticks firmly stuck into the soil at short intervals on each side of the rows, and tie the two strings loosely together here and there with cross-ties.

Storing Apples and Pears.—The recent gales brought down large quantities of Apples and Pears in orchards. This fallen fruit is only fit for present consumption, and, as such, should be placed apart. In view of more gales occurring, it will be advisable to examine all trees on which fruit is approaching maturity, and gather those which part readily from the shoots, storing them in single layers on the shelves, if plenty of shelving exists, and two or three deep if it be limited. It need scarcely be repeated that all kinds of fruit require very tender handling.

PLANTS UNDER GLASS.

By G. H. MATCOCK, Gardener, Laxton Hoe Park, Luton.

Bougainvilleas.—After this date the plants which have remained where they were planted should be dug up with sufficiently large masses of soil, and repotted in a fairly rich soil, care being taken to preserve intact most of the small roots, and to use clean or new pots, and crock them well with small pieces. After potting, stand the plants in a cold frame or pit for a few weeks, and keep them close until such time as the roots begin to grow again. If flowers are required early, those plants which were kept in pots the whole season will furnish them, the stopping of their shoots being now discontinued. Let the shoots be tied out, and the plants made a trim-looking as is consistent with a graceful appearance, and if green-fly appears on them, fumigate the frames without delay.

Winter-flowering Carnations.—These will not be the better for being left out-of-doors any longer, and more especially if the garden is low-lying. Fasten the flower-stems to neat green-painted sticks, cleaning the plants and the surface of the soil, and washing the pots; placing them afterwards in a well-lighted and ventilated span-roofed house, and near the roof-glass if possible, or, at any rate, in as light a position as possible. Under this kind of treatment the flower-spikes do not become drawn, and the flowers open satisfactorily. No fire-heat will be needed excepting, perhaps, a small amount in the day-time when the weather is dull, wet, or foggy. It benefits the plants to afford liquid manure-water once or twice a week; and occasionally, as a change of diet, a spoonful per pot of patent manure, such as Olay's.

Eucharis.—The leaves of the plant should be cleaned of mealy-bug and Thrips, if these be present, by using a sponge dipped in some kind of insecticide, never allowing them to get badly infested before taking means to rid the plants of these pests. It does the plants good to wash the pots occasionally, in

fact, whenever the leaves of the plants themselves are cleaned. Failing any other means, soft soap at the rate of 4 oz. to the gallon of rain-water, and heated to 100°, will serve the purpose of washing the leaves. Such of the plants as are well rooted, and have matured their foliage, and been rested for a few weeks by lessening the quantity of water at the root, and keeping the plants in a house with a slightly lesser degree of warmth, will, if given more warmth, and a few thorough soakings of water and liquid-manure, soon come into flower. The plants should be started in batches in order to lengthen the flowering season. Some of the plants will be growing strongly in a high temperature, and when growth is completed, these should be rested. We never dry off our plants, and seldom repot them, nor is the habit known in this garden.

Euphorbia jacquiniiflora and pulcherrima.—These plants are now growing strongly, and should be assisted with frequent applications of farmyard manure-water, with chemical manures as a change. The plants should now be placed in a structure provided with the means of heating it, so as to keep up a warmth of 60° and dissipate damp, air being afforded only in fine weather. If the plants do not flag on sunny days, shading should be dispensed with, and this rule applies to all stove and greenhouse plants.

THE APIARY.

By EXPERT.

What Bees accompany a Swarm.—A swarm is composed of the queen, for there will not be another in the hive for eight or nine days, few or many drones, and some thousands of workers. Worker-bees are nurse-bees for the first fortnight of their short lives, and as there will be thousands of grubs left in the hive when the swarm leaves, these bees for feeding purposes alone will be in request. Apart from their services as nurse-bees being required, it is a well-known fact that it is the old bees mainly that accompany or form the swarm. Bees live only about five or six weeks in the summer, and six months if hatched at the end of the season when work is about over. The queen commences to lay in January, when she deposits a few eggs in the centre-comb, and she continues her work throughout the year until July or August. During the summer months she lays between two and three thousand eggs a day.

A Mammoth Bee-hive.—The biggest bee-hive in the world is a natural one in Kentucky, known as the "Mammoth Bee-hive." It is in reality a huge cave, the main compartment of which is 150 feet high, the floor covering 10 acres in extent. The bee-hive is of solid rock, the roof having been entirely honey-combed by bees. M. Bertrand, a famous French bee-keeper, has hives containing twenty-six frames.

Shallow Frames for Extracting.—There seems to be a general inclination just now, on the part of those who keep bees more or less for profit, to favour a system of working for extracted honey in preference to that where the produce is intended to be sold in the comb. A good many reasons have contributed to bring about this feeling, but no doubt the low price obtainable for fine comb-honey, and the difficulty of finding a market for it last season, have been the main causes of complaint. Sections (if they are to be secured in fine condition and quality) are not easily got, for a good deal of care and trouble are involved in their production; and when the bee-keeper, after all his expenditure of time and labour, is offered perhaps less than one half the price he counted on, he is apt to feel discouraged, and inclined to cast about for a remedy for what is to him a very unsatisfactory state of things. We have been brought into communication in various ways with a goodly number of bee-keepers, and there seems to be but one opinion as to the way in which an improvement can be effected. In other words, they are "going in for extracting," either wholly, or as nearly so as to make comb honey a very minor point with them. This being so, it behoves us to follow the bent of public opinion; and although it may be thought early in the season to give advice now, we deem it useful to say a few words to those who are already maturing their plans for another year. The main point for consideration being the very perceptible fall in the value of British honey experienced in the autumn of 1885, it becomes necessary to consider by what means the largest amount of the product may be obtained at the smallest outlay of time and money, in order to secure such an equivalent in quantity as will counterbalance lower price.

APPOINTMENTS FOR THE ENSUING WEEK.

SALES.

MONDAY,	SEPT. 13	Bulbs at Protheroe & Morris' Rooms.
		Twelfth Annual Trade Sale of Plants at Dyson's Lane Nurseries, Upper Edmonton, by Protheroe & Morris.
		Sale of Freehold Building Land at Rayleigh, Essex, by Protheroe & Morris.
TUESDAY,	SEPT. 14	Bulbs, at Stevens' Rooms.
		Bulbs at Protheroe & Morris' Rooms.
		Annual Sale of Heaths, at the Nurseries, Lee, Kent, by order of Messrs. B. Maller & Sons, by Protheroe & Morris.
WEDNESDAY,	SEPT. 15	Bulbs, at Stevens' Rooms.
		Bulbs at Protheroe & Morris' Rooms.
		Annual Sale of Plants at The Nurseries, S. Woodford, by order of Mr. John Fraser, by Protheroe & Morris.
THURSDAY,	SEPT. 16	Sale of land at Wanborough, near Guildford, also the Lease of the Ashford Nursery, at the Auction Mart, Tokenhouse Yard, by Protheroe & Morris.
		Bulbs, at Stevens' Rooms.
		Bulbs at Protheroe & Morris' Rooms.
FRIDAY,	SEPT. 17	Twenty-ninth Annual Trade Sale of Plants at the Brimsdown Nurseries, Enfield Highway, by Protheroe & Morris.
		Bulbs, at Stevens' Rooms.
		Bulbs and Orchids at Protheroe & Morris' Rooms.
		Sixteenth Annual Sale of Heaths at the Longlands Nursery, Rickup, by Protheroe & Morris.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—57.8°.

ACTUAL TEMPERATURES:—

LONDON.—September 8: Max., 61°; Min., 52°.

PROVINCES.—September 8: Max., 60°; Min., 51°.

Influence of Stock on Scion. THE influence of the stock upon the graft is a subject which has been much debated, but it has long been observed that fruit-trees, and especially many varieties of dessert Pears, are modified in their characters, according to the nature of the stock on which they are grafted. It has been remarked, in fact, that if the essential peculiarities of these varieties have not been changed, their vigour and early fruit-bearing, as well as the size, colour, and flavour of their fruits were noticeably modified, according to whether they were grafted upon the free stock or on the Quince.

But hitherto, although these observations relate to one of the most important questions in vegetable physiology, they have not been made the object of scientific tabulation, which would have furnished the indispensable precision and exactitude. Some few years since some experiments were made by a French observer, whose name we have unfortunately mislaid, but which are of the greatest importance in connection with this subject.

As it was necessary to proceed under exactly identical conditions, ripe fruits of *Triomphe de Jodoigne*, which were gathered from two trees, one grafted on the free stock, and the other on the Quince, were submitted to analysis during three consecutive years.

It is almost needless to add that the two Pears were of the same age (fifteen years); their vegetation had always been normal; they were trained in the same manner, and were planted side by side; consequently, their roots were in the same soil.

Neither to the composition of the soil, age of the trees, nor exposure, which frequently have so much influence on the size and flavour of fruits, can be attributed any of the results under such circumstances as these.

From reading this table, which chronicles the result of analyses made during 1894, '95,

and '96, it may easily be deduced:—1st. That the average weight of fruits gathered on the *Triomphe de Jodoigne* grafted on the Quince far exceeds that of the fruits of the same variety grafted on the free stock; 2nd. That the density of the juice of these same fruits is higher in the former than in the latter case; 3rd. That the proportion of free acid (represented by sulphuric acid, SO_3HO) is greater in the juice expressed from fruits gathered on the variety under consideration, and grafted on the Quince, than in the juice of the fruits of the same variety grafted on the free stock. 4th. Finally, and this is the most important fact and one it is especially desirable to establish, the total quantity of sugar contained in the juice of fruits gathered from *Triomphe de Jodoigne* grafted on the Quince is markedly higher than that in the juice of fruits from the same variety when grown on the free stock; in fact, there is observable an excess of nearly 9 grains of sugar per litre in plants grafted on the Quince. Then, for trees producing annually each about 300 fruits, there would be from 280 to 406 grammes of sugar according to the stock, the total quantity of sugar attained being 7 kilos. with the *Triomphe de Jodoigne*

FIG. 55.—

A, *Calceolaria arachnoidea*; colour purple. Natural size.
B, The *Calceolaria* of sixty years ago.

on the free stock, while it exceeded 11 kilos. with the same variety grafted on the Quince.

From the whole of these experiments it is proved that the stock exercises a considerable influence upon the graft, since it increases or weakens most of the physiological phenomena of the scion.

We came upon the substance of this note by accident, and unfortunately we have no record either of the name of the observer, nor of the place of publication; but the subject is too important to be passed over.

CALCEOLARIAS, 1835 TO 1897.—The generic name of this beautiful flowering plant has its origin from the word *calceolus*, a little slipper, in allusion to the form of the flower; it was so named by LINNÆUS. The species *C. pinnata* was introduced into this country from Peru by Sir JOSEPH BANKS in 1773. The herbaceous variety as we know it to-day is the outcome of a lengthened series of hybridising and cross-fertilisation. In 1820 only seven species were known in this country, the handsomest of which was *C. corymbosa*, the flowers of which are yellow, and the form of the flower that of a sack-purse. From that time till 1830 several other species were introduced from Chili, two of which had purple flowers. As soon as these plants bloomed in the nursery of Messrs. YOUNG, of Epsom, their foreman, Mr. PENNY, made an attempt to hybridise them, and the result was a number of beautiful varieties. In 1831 the first spotted variety was introduced into this country. It was found easy to cross the true sub-shrubby species with the herbaceous, and these remarkable productions incited many persons to raise

varieties between them. Amongst the first to raise *H. Calceolarias* were J. PLANT, a florist, of Chaddle MAJOR of Knostrop, near Leeds; BARNES, gardener to W. NORMAN, Esq., Bromley Hill; GREEN, gardener to Sir E. ANTROBUS, Cheam; whilst a few years later came KINGHORN, gardener to the Earl of KILMOREY; W. H. HOLMES of Derby, Messrs. DICKSONS of Edinburgh, and N. GAINES of Bittersea. Of these raisers, it was H. MAJOR who was the first to make any notable advancement in the *Calceolaria* as a show flower, and it is to his endeavours that we are indebted for the foundation of the fine strains of to-day. At the present moment there are several prominent gardeners who have select strains of this plant, and our leading seedsmen are also continually improving the size and form of the blossoms and the habit of growth; and we may mention Messrs. CARTER, Messrs. SUTTON, and Mr. JAMES, as possessors of some remarkably fine strains. Our small illustrations represent *C. arachnoidea*, fig. A. and an improved type of the *Calceolaria* of 1835, fig. B. and the large one p. 183 that of Messrs. CARTER's Victoria strain taken this season, which they have kindly allowed us to reproduce. The public taste at one time leaned towards the sub-shrubby varieties; but the taste in this direction has greatly declined, and now the herbaceous varieties are generally cultivated. The former were decidedly miffy plants, difficult to keep over the winter, and liable at other seasons to die suddenly without apparent cause. A coloured plate of eighteen varieties of *Calceolarias* is given in the *Floricultural Cabinet* for October, 1835, p. 238, which show the first improvements obtained by the florist, J. PLANT.

"THE JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY."—The August number, forming part I. of volume xxi., is now before us. It appears, on reference to the table of contents, to be stored with interesting matter, of which we may instance "Microscopic Gardening," "Bud Transference and its Effects on Fruit," "Artificial Manures and their Bearing upon Horticultural Practice," "Winter and Spring Bedding in Flower Gardens," "Diseases of Plants," "The Physiology of Pitcher Plants," and "Storing and Preserving of Fruit," these being the titles of papers read at the various meetings of the committees held at the Drill Hall, James Street, Westminster, during the present year, outlines of which have appeared in these pages. We find a number of reports of trials carried out in the Society's garden on Beans, Peas, Strawberries, and a list of the proposed trials to be undertaken during the ensuing year.

A JUBILEE EXHIBITION IN VIENNA.—The Imperial and Royal Horticultural Society of Vienna intends to hold a jubilee exhibition next year in commemoration of the EMPEROR FRANZ JOSEPH's fifty years' reign. This exhibition will remain open during the spring and summer, and will include also four special exhibitions of short duration. Demands for space must be made previous to November 1 of the present year.

BULLETIN OF THE ESSEX TECHNICAL LABORATORIES, CHELMSFORD.—The summer course of three weeks' elementary instruction in the science and practice of horticulture of the County School of Horticulture was held during July, and a class of fourteen pupils attended it. A theoretical and practical examination in both branches of the subject took place during the last week of the term. The examination-papers consisted of questions in the science of horticulture, to be answered by the student orally in some cases, and in writing in others; in the practice of horticulture, and in horticultural operations.

DUTCH HORTICULTURAL AND BOTANICAL SOCIETY.—On the occasion of the meeting of this Society on August 14 last, the Floral Committee awarded First-class Certificates as follows, viz.:—To Mr. C. G. van Tubergen, jun., of Haarlem, for Cactus Dahlias, Bridesmaid, Cycle, Fantasy, and Starfish; to Messrs. E. H. Krelage & Son, of Haarlem, for *Gladiolus gandavensis* Weissé Dame, G. Lemoinei Henriette Renan, G. nanceianus Colonel Gillon, and

Fig. 56.—MODERN TYPES OF CALCEOLARIA HERBACEA BLOOMS. (SEE P. 182.)

Aggdonium japonicum; to Mr. K. Wezelenburg, of Hazerswoude, for *Glyceria spectabilis* foliis variegatis. Certificates of Merit were awarded to Mr. C. G. van Tolbergen, jun., of Haarlem, for *Canna* × *Ami Jules* *Christen*, C. × Vice President Luizet, *Cactus Dahlia* *Cinderella*, and *Kniphofia* × *Surprise*; to Mr. Phil. Benkel, of Hilversum, for *Heliotrope* *Madame Renée André*; and to Mr. K. Wezelenburg, of Hazerswoude, for *Tamarix Odessana*. A Botanical Certificate went to Mr. J. H. Schober, of Putten, for *(Enothera tetrapetala)*. H. C. Zwart, Secretary.

THE SPINELESS GOOSEBERRY.—We find a note by M. Professor EMIL RODIGAS in the *Bulletin d'Arboriculture*, to the effect that plants of this variety sent out by LETELLIER & SON, Caen, had reverted to the original spiny form. This reversion may be due to the goodness of the soil of the horticultural school-garden at Ghent.

BERBERIS VULGARIS AND MILDEW.—In consequence of the common Barberry serving as the host plant of the mildew of corn, *Puccinia graminis*, the Royal Swedish Agricultural Academy in Stockholm, the managers of the Royal domains, and the Royal Agricultural Associations, have requested the railway directors in Sweden to grub up all Barberry-bushes for a minimum distance of 50 metres from all cornfields; and nurserymen are directed to notify in their catalogues that this species of *Berberis* should not be planted in the vicinity of arable land. In this manner it is hoped that the spread of this injurious parasite on corn crops will be greatly lessened.

CAPE FRUIT CULTIVATORS.—I am sorry to see that there are still some farmers at the Cape who think they know all—or enough—about fruit growing. The Cape Government expert recently failed to get an audience at King, outside the Press and officials. I hope, however, his suggested Fruit Growers' Association will catch on. There is still room in the London markets for well-packed Cape garden and orchard produce. Mr. RHODES intends to give increased attention to this matter of fruit-growing in South Africa. He has just received from Australia a large consignment of Citron trees for the Bulawayo district, where they should do well. I trust they may, and that other experiments in the acclimatisation of vegetable life in Rhodesia will also succeed. *The African Critic*.

BOTANICAL MAGAZINE:—

Scheelea Kewensis.—A tropical American species, of which a figure of the crown, together with details of the flowers and fruits are given, the plant having flowered and borne fruit at Kew—a matter of rare occurrence in the case of the larger Palms, as Sir J. HOOKER remarks, in his note accompanying the illustration. The whole plant is 25 feet high to the level of the coma, and the trunk from the ground to the lower leaves measures 8 feet, and 3 feet in girth. The leaves are many, spreading, and decurved, 25 feet long, leaflets crowded in three ranks, spreading and decurved, with pendulous tips.

Cirrhopetalum Curtisii.—A native of the Straits of Malacca, and sent to Kew by Mr. CURTIS, Superintendent of the Garden and Forest Department, Penang. Pseudo-bulbs about an inch apart, and two-thirds of an inch long, ovoid, green, clothed with brown sheaths; leaf 4 to 4½ inches long by nearly an inch broad, linear oblong, very coriaceous, yellowish-green on both surfaces. Scapes solitary from the base of the pseudo-bulbs, 3 to 4 inches long, very slender; flowers numerous, in a crowded umbel, hardly half an inch long; dorsal sepals and petals bright rose-coloured, lateral sepals paler, fading into white in the middle; lip bright yellow.

Helianthus giganteus.—This plant is an old inhabitant of English gardens. *H. giganteus* has been cultivated at Kew since its establishment as a botanic garden.

STOCK-TAKING: AUGUST.—This operation, in the present condition of things social and political, is far from proving so satisfactory as one might desire. Affairs in the near and the far East are in a dislocated condition; at home the ruinous game of "beggars-

my-neighbour" is being busily carried on in several most important trades; and as a natural consequence, trade is deeply affected, as the export record to some extent proves. The total value of the imports for the past month are placed at £33,371,385, against £32,480,473 for the corresponding period last year—or an increase of £890,912. Here is the usual extract from the "summary table" in the Board of Trade Returns for August:—

IMPORTS.	1896.	1897.	Difference.
Total value ...	£ 32,480,473	£ 33,371,385	+ 890,912
(A.) Articles of food and drink—duty free ...	11,087,257	11,718,883	+ 631,626
(B.) Articles of food and drink—dutiable	1,920,668	1,940,789	+ 20,121
Raw materials for textile manufactures ...	2,465,714	2,247,764	— 217,950
Raw materials for sundry industries and manufactures	5,036,984	5,635,240	+ 598,256
(A.) Miscellaneous articles ...	1,013,188	859,078	— 154,110
(B.) Parcel Post ..	54,774	82,551	+ 27,777

Imports of duty-free supplies of food and drink show an increase of £631,626, which is spread over a large area; but cereals do not cut a very satisfactory figure. For instance, there is a decrease of £311,252 in Wheat; of £94,162 in Barley; and of £44,326 in Oats—quantities, in all cases, showing a corresponding reduction. The sensational prices in the American market gave a fillip to prices in the home market—one result being a rise in the price of bread—what the ultimate effect may be has, we think, yet to be seen. The unexpected enhancement of values in the Chicago and New York corn markets might not have occurred had the monthly crop reports been carefully noted, and it would be well for our Board of Agriculture to see to this matter. A brief monthly notice of crop-prospects at home and abroad—that is, for a month or two preceding harvest-time—would certainly be beneficial all round; and a correspondent, who invited the attention of the Board to the subject has, he writes, been promised that the matter shall have consideration. There is plenty of time. One unsatisfactory item in the imports is that of £177,018 set down for increase in the value of manufactured articles. The "decrease" items are metals, chemicals, oils, raw materials for textile manufactures, and "miscellaneous." Our ever-interesting statistics of fruit imports is appended:—

IMPORTS.	1896.	1897.	Difference.
Fruits, raw:—			
Applesbush.	208,335	182,747	— 25,588
Cherries "	5,675	5,577	— 98
Plums "	310,841	471,073	+ 160,232
Pears "	215,392	450,616	+ 235,224
Grapes "	251,361	193,653	— 57,708
Unenumerated "	332,452	344,533	+ 12,081
Onions "	497,846	639,027	+ 141,181
Potatoes cwt.	51,093	68,764	+ 17,671
Vegetables, raw, unenumerated value	£127,931	£186,375	+ £58,444

By-the-way, the imports for the past eight months show an increase of some £11,438,513 over the corresponding period last year. Turning now to our

EXPORTS.

we find there is a falling off for the month to the extent of £1,552,799—that is to say, whilst the exports in August, 1896, were valued at £20,326,796, those for the past month amounted to £18,773,997. The reasons for this have already been noticed. The falling off is principally in articles of food and drink, yarns and textile fabrics, metals, and articles manufactured therefrom excepting machinery, millworks, apparel, and articles of personal use, and also partly-manufactured articles. We can only express the hope here that changes may be effected in the political and social conditions now existing. True, we may not be alone in the

"hobbling" process, but a steady look at the £ & d aspect of things is to be recommended to all concerned. The drop on the eight months' trade is represented by £3,145,774. In the four months of the year still to run this falling off may be recovered.

BULBS FOR THE LONDON PARKS.—Messrs. JAMES CARTER & Co. of High Holborn, for the ninth time, have been honoured with the commands of the First Commissioner of Public Works to supply the whole of the bulbs required for the Royal Parks of London for the present season's planting; and a similar favour from the London County Council for the parks, Gardens, and open spaces under its control.

A LECTURE ON THE CULTIVATION OF VIOLETS was delivered on the 4th inst. by Mr. J. MERRITT, gr. to H.R.H. Princess BEATRICE, at a meeting of the Isle of Wight Horticultural Mutual Improvement Society, at Newport. It was afterwards resolved to abandon the intention to hold a fruit exhibition during the present year. Several Cultural Commendations were awarded to exhibits before the meeting.

PUBLICATIONS RECEIVED.—*Fruit Growing*, a useful shilling handbook, by B. WELLS, Fruit Nurseries, Crawley.—*The Canadian Horticultural* (Ontario), August.—*Report on the Government Gardens and Parks, Nilgiris* (Madras), July. The Curator, Mr. R. L. PROUDLOCK, gives us the information that "the year under review was the first in which the gardens were under the control of the collector of the district instead of under that of the Government botanist. The appointment of a Government botanist is still under correspondence between the Government of India and the Secretary of State. Pending final orders the work has been entrusted to Dr. A. G. BOURNE, the officiating Superintendent of the Central Museum, who will deal with all applications for botanical assistance. In consequence of this arrangement, and the decision to ultimately make Madras the head-quarters of botanical work in this Presidency, the Herbarium and the more valuable portion of the Library hitherto attached to the Government Gardens at Ootacamund have been transferred to Madras." Much necessary work has also been done in the Ootacamund gardens during the past twelve months; and now the garden buildings need enlarging. Mr. PROUDLOCK reports the unusual fact that a "garden which has been in existence for fifty years, and which has nearly three miles of boundary line, is almost entirely unfenced."

—*Agricultural Bulletin of the Malay Peninsula* (Garden and Forest Departments, Straits Settlements), June, includes notes on Rubber-culture, *Ramie* (*Boehmeria nivea*), Sugar, Coffee-pests, Birds useful to the Agriculturist, and Pot-plants.—*Agricultural Gazette of New South Wales* (May) contains much information, including articles on Marketing Citrus Fruit, the Strawberry, Phylloxera, Influence of Bees on Crops, &c.—*Anniversary Address*, by J. H. MAJORS (Royal Society of New South Wales, Sydney) May. The subject of the address is divided into three headings: 1, History of the Society during the past Year; 2, Progress of Science in New South Wales during the past Year; and some Botanical Notes and Jottings.—*The American Florist*, August 7 and 14, a "Convention Number" of special interest as regards both letterpress and illustrations.—*Annual Report of Hawkesbury Agricultural College and Experimental Farm*, Richmond, New South Wales, for 1895.—*Revue Scientifique*, August 21, includes a paper by M. E. PRILLEAUX, on "Maladies des Plantes Agricoles et des Arbres Fruitières et Forestières causées par les Parasites Végétaux."—*Botanische Zeitung*, August 16, and Heft VIII. (also August 16), including "Kenntnis der Polyembryonie von *Allium odoratum*," F. HEGELMAIER.—*The Kew Bulletin* for the months of April, May, June, and July. These numbers contain much very interesting matter, as, for instance, Mycological Flora of the Royal Gardens, Kew; Insects destructive to Plants in West Africa, Fruit-growing at the Cape, Canaigre, Extraction of Gutta-percha from Leaves, Murrum-grass, Eucalyptus Timber for Street-paving, Grafting Sugar-cane, and a List of Kew Publications.

841-95 (Eyre & Spottiswoode).—*Bulletin de la Société Botanique de France* for August.—*Bibliothèque des Sciences Naturelles* (J. B. BAILLIÈRE ET 9, Rue Hauteville, Paris).—*Florilegium Har-* (DE ERVEN LOOSJIS, Haarlem).—*Useful* (Printing Office).—*Annual Report of the Forest* (Madras Presidency, for the year ending 30, 1896 (Government Press, Madras).—*Nouvelles Recherches sur les Nodosités ou Tubercules des* (by C. NAUDIN (Librairie Agricole de son Rustique, 26, Rue Jacob, Paris).—*Journal* (my for September, 1897.—*Botanical Magazine*, (Fruit Culture for Profit, Salisbury series.—*Book of the Department of Agriculture* (Wash-Government Printing Office).

There may be some fifty of these trees from five to six years planted, and although fruiting sparsely hitherto, they this year carry a splendid crop. The trees are somewhat loose growing, and possess the habit of fruiting at the points of the shoots. The fruits are of good size, some quite large, roundish, tending to yellow in colour, with bright red next the sun. I am certain, that could growers of Apples generally see these Ruxley trees now, there would be 10,000 planted this autumn. In every case the trees are assisted to carry the fruit by the aid of props.

Cordon Pears.—One side, and the bald gable end of a large brick building close to Mr. Miller's house, have been utilised by planting cordon Pears. These were planted several years since, and stand

brick floor, 2½ feet below the surface, presumably laid by the monks of old, and on this wall are grown fine young trees that are utilised as needed to fill any vacancies that may occur in the houses. In the home garden a similar high south wall is finely filled from top to bottom, and in every part with good growth, foliage, and fruit of Barrington, Royal George, and Bellegarde Peaches, and Pitmasoa Orange, Veitch's Large Elruge, an I Violet Hative Nectarines, the whole presenting a first-rate example of such hardy fruit-culture.

Melons.—A good many years ago when at Clumber, Mr. Miller raised so good a green-flesh Melon, that he named it after his friend of Welbeck, William Tillery. That variety in an improved form, for the fruits are now more handsomely netted as well as of better shape, is the one chiefly grown at Ruxley, and a first rate variety it is. As a green-flesh form (and the greens usually give good flavour), this is one of the best. William Tillery, like its compeers, Hero of Lockinge and Blenheim Orange, will be a still good class when many successors have been forgotten. A. D.

FIG. 57.—FICUS RADICANS VARIEGATA.

FICUS RADICANS VARIEGATA.

WE represent by fig. 57 a shoot taken from a plant shown by Mr. W. Bull, New and Rare Plant Establishment, King's Road, Chelsea, at a meeting of the Royal Horticultural Society, on the 24th ult., when it was recommended a First class Certificate. The whole of the eight plants noticed on that occasion were freely variegated, the margins of the leaf in all cases being the parts where the variegation commenced. Some of the leaves were almost white. The usefulness of this variegated form, which creates so striking an effect intermixed with other foliage, will be apparent. Judging from the appearance of the plants when exhibited, this variety would appear to be of moderate and slender growth.

KEW NOTES.

A LARGE-FRUITED CACTUS.—The largest fruit we have ever seen produced by any Cactus has lately ripened on an old specimen plant of *Cereus triangularis*, which for many years has been a conspicuous object on the roof of the Cactus house at Kew. The present year has seen this plant at its best, for it has borne over 150 flowers, 30 of them having been open at one time. The flowers are nearly one foot across, the sepals green or yellow, the petals pure white, forming an enormous star with a large cup-like centre, containing a sheaf of slender filaments tipped with yellow anthers. The Kew plant has flowered more or less freely every year, but it has never borne fruit until this year, when, with the hope of getting a good hybrid, pollen of *C. grandiflorus* was placed on the stigma of a single flower of *C. triangularis*. The stamens of the latter had not been removed, and therefore the cross is not certain; but, looking at the fact that the flower thus treated was the only one that set a fruit, it is probable that the cross has been effected. The fruit matured in about three months, and when ripe it weighed exactly 2 lbs., its size and shape being those of an ostrich's egg, and its colour bright crimson. The rind was an eighth of an inch in thickness, and it was filled with soft, white pulp, through which the small black shining seeds were scattered. This pulp was decidedly palatable, being sweet, very slightly acid, whilst the seeds were in no way disagreeable. It is probable that with a little management a large crop of fruit might be borne annually by strong plants of this species of Cactus; and as it is easily grown, it is worth trying—in warm countries, at any rate. In my opinion it is far superior to the fruits of any *Opuntia* that I have tasted; moreover, its beautiful colour and size would recommend it as a good fruit for the tables of the wealthy. Philip Miller speaks of it as "the best flavoured of any of the sorts," and states that it was cultivated in Martinique for its fruits before 1759. W. W.

ES FROM RUXLEY LODGE.

his returns of the fruit crops in the Claygate of Surrey, Mr. J. Miller places Apples as "average." Judged, however, by the general of the season, his crop at Ruxley Lodge is erably above, yet as compared with what it be for the exceeding breadth of the orchards it is small. Whilst there may be seen, on rather old trees, capital crops of Keswick Max Coddins, Lord Suffield, Lord Derby, aim Oange, King and Collini Pippins, and few others, there are very few fruits on trees, with one notable exception, and that is arkable a one as to call for special notice. In lying orchard on grass, on a very stiff clay soil, s at intervals amongst other varieties, are many andards of Yorkshire Beauty, as named there, gh I think the variety has other synonyms.

some 15 inches apart. Poor Pear season as this is, yet there is on these cordons generally quite a good sprinkling of fruit, and some of the best dessert varieties are really fruiting well, but others, not so fruiting, carried good crops last year. Mr. Miller, I observed, did not adopt the usual practice of training his trees obliquely but vertically; and the trees seem to fruit just as well, and are admirably furnished. Thus there is no rule without the exception. The cordons ranged from 16 to 20 feet in height. It is a capital example of how efficiently to utilise good wall aspects by planting them with Pear-trees.

Peaches, &c.—Although these fruits and Nectarines are grown in great quantities under glass, they are not the less remarkably well grown on walls out of doors, the Scotch love of wall training asserting itself. There is a south wall in the old monastic garden, in the bottom of the border of which, is still left the

HOME CORRESPONDENCE.

JUDGING AT HORTICULTURAL EXHIBITIONS.—

Allow me a small space in your columns to ventilate my ideas in regard to the judging of exhibits, a matter that frequently affords subject for debate in the horticultural press. In the more important horticultural societies, great consideration is given to the selection of the judges, and these men almost invariably perform their duties to the best of their ability in accordance with the views that they entertain in regard to the merits, and condition of the exhibits. These views, however, often conflict with those of the exhibitors and visitors. In reviewing the results of awards made at agricultural shows, we frequently observe the decision given by the judges at one place completely reversed a few days later at another show without any apparent change taking place in the condition of the animals. This irregularity is looked upon by our agricultural brethren as a matter of course consequent upon the change of judges, and there is nothing said about it. In the same way, two sets of judges adjudicating upon a class of horticultural exhibits would sometimes arrive at different results. This, however, should not be; and the chances of eccentric judgment would be rendered almost impossible if the methods of estimating the values of various points were uniform. The dissatisfaction experienced in Grape judging last year, and the subsequent discussion in these pages with little prospect of a better understanding being arrived at in future, will suffice for my offering a few suggestions that may enable us to see eye to eye as regards the value of varieties in competition. We have little guidance in this matter from the code issued by the Royal Horticultural Society in regard to fruit. The relative value of the properties in single specimens of flowers and vegetables are, however, exhaustively treated, although no direct attempt has been made to deal in the same manner with genus, species, and variety. Neither, as was expected, has a systematic method of judging, especially collections, been formulated for universal adoption by societies. Then what is to be done? The only data we have on this important subject appeared in these columns a few years ago, and is now embodied in the *Horticultural Handbook* (Blackwood & Sons). The method therein propounded seems adequate for the purpose of adjudication, and the estimate given on the knotty point of relative value in the various classes of exhibits is as near as possible founded on an equitable and popular basis. In the second edition of the publication referred to—which, by the way, has the imprimatur of Malcolm Dunn, the recognised leader of gardening thought and practice in Scotland at the present time—there is a list of Grapes classified in the order in which they are esteemed, with an estimate of their value proportionate to the usefulness of the variety for dessert, combined with its exhibition qualities. The varieties are divided into three classes, those with Muscat flavour and large berries being at the top of the list, with Black Hamburg, Mrs. Pearson, Madresfield Court, and Duke of Buccleuch, following. These are followed by such varieties as Buckland Sweetwater, Gros Colman, Foster's Seedling, Lady Downs, while a shade farther down the scale are found Alnwick Seedling, Trebbiano, Gros Maroc, Raisin de Calabre, &c. It is clear to all, that there is a wide disparity in the natural merits of the varieties named, which should be followed with a corresponding depreciation in the rate of value in competition. In fixing a rate of maximum value for the varieties with both flavour and appearance, due regard should be paid to the standard prescribed for measuring the cultural merits, so that one factor may not neutralise a proper and equitable estimate of the other. Allowing five points as maximum for cultural merit, and one for relative value, seems a fair proportion to strike between the two elements. In the latter case, fractions of a third, a half, and quarter, would require to be used, or decimals may be employed as in the list and tables already referred to. The metric system of calculation when minute degrees of difference exist is eminently satisfactory, being simple, and capable of extension to the 100th part or lower. I heartily agree with the system promulgated in the publication from which I have been quoting, especially in dealing with cultural and relative value separately, and if this method, or a better one, if possible, were adopted by judges generally, we might claim to have inaugurated during the Queen's reign, although at the eleventh hour, a just and intelligible system of judging at exhibitions, which we do not at present possess. I intended to have

made a few remarks on exhibiting unripe against ripe Grapes, with a few observations on mixed collections, but as I have exceeded the limit of an ordinary letter, I will do so in a future issue. *Avonshire Lad*.

STATICES.—A genus of plants, inhabitants of saline districts and the seashore, mostly of Western Asia, deserve to be more generally cultivated in our gardens than is the case at the present time, being of easy culture, of compact, dwarf habit, and very free-flowering and enduring, some of the species lasting in bloom for a long time, notably, *S. profusa*; indeed, the variety might be termed perpetual-flowering, as when a good number of plants are grown, it is possible to have quantities of bloom the whole year. The colour, too, of this species is pleasing, and one that we do not often get in flowers, the calyx being purple, and the corolla white. In my opinion, the best for general purposes are *S. brassicifolia*, *S. imbricata*, a native of Teneriffe; *S. Gilberti*, and *S. Butcheri*. These resemble each other closely, and being of stronger growth than *S. profusa*, make large specimens suitable for exhibition. The compost which suits these plants is one that consists of good fibry loam three-fifths, one fifth leaf-soil, and one fifth decayed oxen-dung in a dry state, silver-sand being liberally added to the mixture. The plants should be grown in a temperature of 50° to 65°, a close atmosphere being avoided during the flowering-time. The flowers, which are "everlasting," are invaluable when cut for house-decoration during the winter. The above kinds may be increased by cuttings inserted in small pots, covered with a layer of sand during early spring, and placed under a bell glass in an intermediate temperature. All greenhouse species, contrariwise to the ordinary practice with other plants, should not be rested during the winter, but be kept gently growing all the time. *H. T. M., Stoneleigh*.

BLACKBERRIES.—Referring to "A. D.'s" note in your issue for August 28, I have grown *Rubus laciniatus* on a heavy, almost clayey, dry soil, somewhat stony. The brambles are planted on a bank 2½ feet high, and are 5 feet apart, covering an arch of wire-trellis 12 feet over and 80 feet long, running east to west. The stout rods are fruiting very heavily this summer, and the berries are exceedingly large. I commenced to gather ripe fruits on Aug. 2, and during the following week I gathered 40 lb. for preserving-purposes. Like "A. D.," I am strongly of opinion that were our market-growers to cultivate this delicious fruit, they would find a quick sale for it. *J. S.*

TROPICAL FRUITS FOR THE TABLE.—Mr. Clarke does not appear to have considered this subject in all its bearings. Of the class of fruit he specially refers to, i.e., Custard-apples, Avocado Pears, Mangoes, &c., it is very certain that the general taste does not run this way, in fact, judging from the samples reaching this country, they are one and all beyond comparison inferior to a good Pear or Orange. I think I may safely state that there is not a tropical fruit which is brought into this country with which I am not well acquainted, and, except those which are familiar, such as the Pineapple, Banana, &c., they are only to be considered as curiosities and fit only for window-shows—few are worth eating, not even the beautiful Prickly-Pear. Of tropical and sub-tropical fruits we have abundance, from the aristocratic Pine, to the humble but equally good Orange, and anyone who cannot find a sufficient variety of English and foreign fruits the year round, must be exceedingly hard to please. It is desirable that such fruits as the Mango, Prickly Pear, Avocado Pear, Custard-apple, &c., should be known, but they are simply expensive curiosities, and fade into insignificance beside the humble Strawberry, or even the ripe Gooseberry, of our gardens. There is too much time given to praising the foreign fruit, because we know so little about it; we hear the praises of the Cloudberry, the Japanese Wineberry, and others, but having both grown and eaten these, and many of their relations, I have not found one to compare with a good English Raspberry in any single point. Judging from the samples coming to this country, the best fruits appear to be English, and close on these are the fruits from the warm temperate zone, which include Oranges, Grapes, Peaches, &c. The same remarks apply to Nuts, of which, perhaps, the best foreign ones are the American Butter-nut and the Hickory-nut; but these are both surpassed by the Kent Cob and the good old Walnut. *Thos. Fletcher, Gruppenhall, Cheshire*.

FRUIT CROPS IN ESSEX.—In this district the Apple crop is less than half a crop, and in our garden Keswick Codlin, Warner's King, and King of the

Pippins are the best cropped varieties. The crop is under the average. Sweet and M. Cherries were a bad crop on standard trees; on headed trees only about one quarter of the crop. The Plums generally were under the average. In regard to small fruits, the Strawberry crop was one, but the season was short owing to the drought and Currants and Gooseberries were a thin crop. Fruit-trees carried a wealth of blossom, to which late frosts we had in May proved fatal. *J. Richard, Blythwood Gardens, Stansted, Essex*.

EARLY FROST.—On the 4th inst. we received 4° of frost in the Blane Valley. Hoar frost lay heavy; and during the early part of the morning the sun shone out brightly. The effect of this was that the young growths on Bay Laurels and *Rhododendrons* were destroyed. *D. Brough, Dunn Castle Gardens, Blane, Stirlingshire*.

OROBANCHE SPECIOSA.—When at Carton Kildare, recently, Mr. Black showed me a very pretty white-flowered parasite, under the above name, and flowering quite freely on the roots of a common Broad Bean, which had been reared from sown, presumably, with those of its foster mother. There are four *Orobanches* in *Index Kewensis*, and this name, but the plant I saw at Carton is beautiful enough to be grown for its flowers, apart from interest as a parasite. The stems are chocolate-purple with dense white hairs, and the flowers large for *Orobanche*, nearly pure white, with slight pink veining. I understood Mr. Black to say that Mr. Thompson of Ipswich supplied the seeds, and perhaps he can tell us more of the plant's history and habitat. *F. W. B.*

THE REGENT'S PARK ZOOLOGICAL GARDENS.

It may be assumed that most persons who visit the famous Zoological Garden are attracted thither by the specimens of beast and reptile to be seen; they pause to admire the beauty of the garden, the summer bedding, it is merely an incident of the hour. Yet a person capable of ordinary observation is bound to notice that the beasts' houses are set at considerable distances apart, among kept lawns, shrubberies, and beautiful flower Summer bedding as we practice it at the present is often a compromise between the massing of only just discarded, and the mixed style of the Cecus border. The greater the number of uncoloured species of plants included, while neatness is preserved, and a sufficient amount of colour maintained throughout the season, the more commendation does its execution command.

The best type of summer-bedding is well illustrated in these gardens, and they are as well worthy of a gardener desirous of obtaining new ideas as the best of our London Parks.

Having said this much, it is hardly necessary to add, that beds of one species of plant, massed Pelargoniums or Calceolarias, without being relieved by other plants, are not to be recommended. On the contrary, most of the beds of appreciable size, contain half-a-dozen species, fewer, then two or more edgings are used.

Entering by the north gate, there runs a border upon a terrace on the right side, containing miscellaneous plants as Palms, Fuchsias, Newland Flax, Celosias, Alternantheras, Lobelia (blue white-flowered), and Mesembryanthemum cord variegatum. These are planted in such a way that the effect is good. Opposite this border is on the grass, planted with Palms, but carpeted with *Asparagus plumosus*, among which can be seen flowered Lobelia. The whole is surrounded by *Ophiopogon*, *Jaburan variegata*, and *Mesembryanthemum*, and the bed is edged with *Echeverias*.

In front of the monkey-house there is a pretty flower-garden in three sections, containing diamond-shaped and other beds. The first of these sections have been planted similar to the picture during the summer has been a pleasing one—the result of tasteful planting and persistent attention afterwards.

The feature first observed in these beds consists of Celosias, which are used freely in several of

Mr. Young, who has superintended the gardens for a number of years, has undoubtedly possessed himself of a magnificent strain, the plants producing the long feathery plumes of richest colours so much admired, but so scarce in gardens. But beyond this there has been care exercised that no inferior varieties have been planted in the beds. The best varieties of *Celosia*, as most of us know, produce but little seed, and even from seed from the most perfect plants there may arise a number of indifferent varieties.

Mr. Young raises his plants in pots, and none is put into the beds until the quality of the flower can be estimated. In no other way could such satisfactory effect be obtained. The finest strain of *Celosias* will run back to an indifferent one in a marvellously short space of time if there be not the strictest vigilance exercised.

Looking at one of the beds in this flower garden, we find it planted with *Verbena venosa*, with a band around it of *Iresine Lindenii*, and edged deeply with *Lysimachia Nummularia aurea* (Golden Creeping Jenny). Another one has a centre of fibrous-rooted *Begonias*, having rose-coloured flowers, surrounded with a few *Pelargoniums*, and edged with *Alyssum saxatile variegatum*. The *Celosias* are used as "dot" plants in the centre of the bed, in some of which were counted as many as twenty-two. Several plants mentioned above will please anyone who may not yet have tried them for the purpose. The *Lysimachia* makes an excellent edging to flower-beds, and is very little trouble if it be allowed to occupy the same position for several years. It is a rich and beautiful colour. The *Pelargonium Omphalo*, possessing green leaves and pink flowers, is admirable.

A round bed at the end of the Monkey-house is planted with *Lobelia cardinalis* var. *Firefly* rising above *Chlorophytum*, with a dwarf-growing *Fuchsia* around them. There are some more flower-beds in front of the barn-dens; they run along the side of the path, and are backed by a neat shrubbery. One of these beds contained *Pelargoniums*, surrounded by a band of *Veronica Hendersonii* variegata, then Golden Fleece *Pelargonium*, and *Bluestone Lobelia*. Two other beds contain dot-plants of *Abutilon Souvenir de Bonn*, planted above *Pelargoniums*, and edged with a white-leaved *Pelargonium* named *Princess Alexandra*, and then the Golden-leaved *Lysimachia*. This *Pelargonium* is a gem, but it is very delicate also. The roots are taken up, and propagation is effected in spring, but it is worth the trouble. The centre bed in the design is filled with the newer strain of *Cannas*, with tall plants of *Iresine* around them, and *Lysimachia*. The *Cannas* have bloomed admirably. In another part of the gardens we noticed a large bed of *Hydrangea paniculata grandiflora*, above Golden Privet and *Antirrhinum* mixed together, and edged with *Acalyphas* and *Lysimachias*.

Violas have been excellent, and double-flowered *Zonias* also.

In front of the saloon there are many more beds cut out on the grass. Between and about these are clumps of Bamboos, and during the summer months, large plants of *Dracena australis*, *Agave americana*, *Phoenix reclinata* and other Palms, *Ficus elastica*, &c., are seen. Here is the boldest treatment in the gardens, and some of the beds containing large, fine yellow-coloured *Ricinus*, and similar plants, look admirable. *Acacia lophantha* and *Araucaria excelsa* are planted in the beds, and where dwarfier plants are employed, wherever practicable, the fine *Celosias*, some of them of deepest colour, others pure golden yellow are used.

We have not attempted to describe fully the plants in every bed, but merely to convey an idea upon what system the whole bedding is carried out, and of the success that follows. It may not be seen at its best now, for the autumn rains have caused a little rank growth since these notes were taken, but a visit next summer should afford pleasure and instruction.

SUNFLOWER-PITH.—The lightest substance known is said to be the pith of the Sunflower, with a specific gravity of 0.028, while Elder-pith—hitherto recognised as the lightest substance—has a specific gravity of 0.09, reindeer's hair 0.1, and cork 0.24. For life-saving appliances at sea, cork with a buoyancy of one to five, or reindeer's hair with one of one to ten, has been used, whilst the pith of the Sunflower has a buoyancy of one to thirty-five.

SOCIETIES.

ROYAL HORTICULTURAL.

SEPTEMBER 7.—There was a better display at the meeting held on Tuesday last in the Drill Hall, Westminster, than on the last occasion. A considerable number of Orchids was staged; and collections of *Dahlia* blooms, lady flowers, and several miscellaneous groups of plants, accounted for a considerable amount of space. There were some very fine plants of *Eucharis grandiflora* in bloom, a large group of *Crotons*, and a magnificent display of *Nepenthes* and *Sarracenias*, the former of which served well to illustrate the exceedingly instructive and interesting lecture upon that genus delivered by Mr. Harry Veitch. By the Floral Committee only four awards were made, viz., a First-class Certificate to a hybrid *Nepenthes* from Messrs. JAS. VEITCH & SONS, LTD., and Awards of Merit to a *Dahlia*, a *Michaelmas Daisy*, and to *Hibiscus Manihot*. There was a considerable amount of fruit staged, including large collections from the Queen's garden at Frogmore, and Lord Percy's at Syon. Several seedling Melons were shown, and an Award of Merit was recommended to a variety from Mr. HARRIS, Droymore Gardens.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. JNO. FRASER, H. B. MAY, JNO. JENNINGS, GEO. PAUL, C. J. SALTER, W. BAIN, J. W. BARR, GEO. GORDON, J. D. PAWLE, H. TURNER, CHAS. T. DRURY, GEO. NICHOLSON, R. HOGG, and CHAS. JEFFERIES.

Messrs. CUTBUSH & SON exhibited a group of plants (of *Nerine Fothergillii* major in bloom, interspersed with a few Ferns).

Mr. T. S. WARE, Hale Farm Nurseries, near Tottenham, staged a large group of hardy flowers, as did also Messrs. BARR & SON, King Street, Covent Garden, London. In both cases a Bronze Bankian Medal was awarded.

Messrs. BARR & SON exhibited an effective *Kniphofia* named *Corallina superba*, also a deep-coloured *Gladiolus*, *J. Laing*; and a double-flowered yellow *Datura* known as *Golden Queen*, a sort of hose-in-hose flower.

Messrs. DOBBIE & CO. exhibited a fine lot of blooms of French Marigolds from their Nursery at Orpington in Kent, the strain of which was remarkable for quality.

A group of *Eucharis grandiflora* plants in bloom was shown by Mr. F. KNIGHT EAMES, Fulwell Nursery, Twickenham. The plants were very large, and well-flowered (Silver Flora Medal).

From Messrs. F. SANDER & CO., St Albans, was shown a number of *Gloxinia* blooms of good strains; and Mr. W. J. GODFREY, Exmouth Nurseries, Devon, had two white-flowered Japanese *Chrysanthemums*, named respectively *Queen of the Earlies* and *Barbara Forbes*.

An Award of Merit was obtained by Mr. W. PETERS, Givons Grove, Leatherhead, for a showy variety of *Michaelmas Daisy* known as *Mrs. W. Peters*. Plants two years old, and others raised from cuttings during the present year, were exhibited. The flowers are numerous, but small, white, with yellow disc.

Messrs. E. G. REID, of Beckenham Hill, had several sprays of new *Cannas*; and Mr. EMPSON, gr. to Mrs. WINFIELD, and Mr. FARR, gr. to A. PEARS, Esq., Isleworth, showed new *Crotons*, but no award was made. A variety of *Primula obconica*, with slightly fringed flowers, came from Mr. THOS. LOWSON, Ospringe House Nurseries, Faversham. A number of sprays of *Cannas*, representing about a score varieties, was shown by Mr. ROSE, OWEN, Maidenhead.

Some beautiful specimens of *Nepenthes* came from Messrs. JAS. VEITCH & SONS, Royal Nurseries, Chelsea, most of them strong, healthy plants, with good pitchers. Like all such exhibits from the Chelsea establishment, it was very representative, both of the original species and of garden hybrids. We noticed specimens of *N. Cheloni*, *N. Curtisii*, *Burkei*, *Hookeriana*, *Mastersiana*, several plants showing variability in colour of the pitcher; *N. Morganii*, *Mixta* (one of the recent hybrids figured in the *Gardener's Chronicle*, January 14, 1893), *N. hybrida* var. *Curtisii*, *Dominiana*, also *marginata*, *Purvillei*, &c. One new hybrid was shown, named *N. Tiveyi*, obtained from a cross between *N. Veitchii* and *N. Curtisii* *superba* ♀. The pitcher is pale green blotched frequently with red, about 6 inches long, wings deep, and having long teeth at the margins; margin of mouth nearly an inch wide, deep brownish-red in colour, prettily lined. Lid erect, and very small in proportion to the mouth of the pitcher. The plant bore six leaves, and each carried a pitcher. This handsome hybrid was awarded a First-class Certificate.

Messrs. JAS. VEITCH & SONS also exhibited sprays of *Robinia hispida*, *Acer palmatum sanguineum*, *Hymenanthera crassifolia*, *Hibiscus celsatus* and *H. totus albus*, *H. Lady Stanley*, *Andromeda arborea*, and plants in bloom of *Acidanthera bicolor* (figured in *Gardener's Chronicle*, October 3, 1896) (Silver-gilt Flora Medal).

An extensive group of *Crotons* was shown by Mr. W. FARR, gr. to A. PEARS, Esq., Spring Grove, Isleworth. These were arranged on the floor in the centre of the hall, and occupied a considerable amount of space. Many finely-coloured specimens were observed, and the group was one that would have done credit to any private establishment (Silver Flora Medal).

Mr. Chapman, gr. to R. I. MEASURES, Esq., Cambridge Lodge, Camberwell, obtained a Silver-gilt Flora Medal for a group of *Sarracenias*, *Darlingtonia*, and *Cephalotus*.

Sarracenias *Chelsoni*, *Atkinsoniana*, *Courtii* *crispata*, *Maddisoniana*, *Wrigleyana*, and *melanophoda* were noticed, and some very pretty plants were included.

From Sir TREVOR LAWRENCE's garden at Burford, Mr. Bain exhibited some capital *Peutastemon* grown from seed sown on February 13 last, also sprays of *Lobelia cardinalis* var. *Carmine Gem*, *L. fulgens violacea* (a distinct and pretty variety); flowers of *Mina lobata*, &c.

Messrs. J. CHEAL & SONS, Lowfield Nursery, Crawley, made an exhibit of *Dahlia* blooms of the *Pompon*, *show*, *Cactus*, and single-flowered sections. An Award of Merit was recommended to the variety *F. C. Pawle*, a scarlet-coloured *Cactus*, with a shade of purple. A Silver Flora Medal was awarded to the exhibit.

A collection of *Dahlia* blooms was shown by Mr. ERIC F. SUCH, Maidenhead; and Mr. J. WALKER, of Thame, Oxon., was awarded a Silver Bankian Medal for an exhibit containing upwards of a hundred *Dahlia* blooms, chiefly of show and *Cactus* varieties.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. JAS. O'BRIEN (Hon. Sec.), THOS. STATTER, J. GABRIEL, H. M. POLLETT, F. J. THORNE, T. W. BOLD, H. J. CHAPMAN, A. H. SMEE, J. DOUGLAS, T. B. HEYWOOD, and C. WINN.

Messrs. JAS. VEITCH & SONS, Ltd., Royal Exotic Nursery, King's Road, Chelsea, staged a fine group, rich in beautiful hybrids, and especially in hybrid *Cattleyas* and *Laelio-Cattleyas*, of their own production, who have done so much to extend the number of showy Orchids which flower in the autumn and winter. One of the finest on the present occasion was *Cattleya* × *Euphrasia* (*superba* ♂, × *Warszewiczii* ♀), which had, when first flowered, in a weak state, been awarded an Award of Merit, but was now unanimously voted a First-class Certificate. The fine flower was of perfect shape, the segments of firm texture, and well displayed; sepals and petals light purplish-rose colour; lip very broad and handsome, in colour yellow at the base, with purple markings, the front lobe of a glowing purplish ruby-red, with a very narrow lavender-coloured margin. Another pretty novelty, shown for the first time, was *Cattleya* × *Melpomene* (*Forbesii* ♀, *Mendellii* ♂), a medium-sized flower, of a clear bluish-white, with lilac veining, the base and centre of the lip being yellow, with a few purple markings and raised processes, which plainly indicated *C. Forbesii*. Other handsome hybrids in Messrs. VEITCH's group were *Laelio-Cattleya* × *Epicasta* (*L. pumila* × *C. Warszewiczii*), *L.-C.* × *Eunomia* (*L. pumila* × *C. Gaskelliana*), *L.-C.* × *Callistoglossa* (*C. Warszewiczii* × *L. purpurata*), *L.-C.* × *Clonia superba* (*L.-C. elegans* *Turneri* × *C. Warszewiczii*), *L.-C.* × *Parysatis* (*C. Bowringiana* × *L. pumila*), *L.-C.* × *Stella* (*L.-C. elegans* var. *L. crispata*); varieties of *L.-C.* × *Nyssa* (*L. crispata* × *C. Warszewiczii*), and *C. x Wondlandi* (*C. Warszewiczii* × *C. Bowringiana*), all very handsome and distinct gains. Among the *Cypripediums* were a grand variety of *C. tonsum*, with three flowers; a fine *C. x Coeanthum* *superbum*, with twelve flowers; *C. Charlesworthii*, with sixteen finely-coloured blooms; *C. x Morganii* *langleyensis*, *C. x Mrs. Canham*, *C. x Carnusianum*, *Veitchii* variety, *C. x Melanthus*, *C. x Janet*, *C. x Hornblum*, *C. x Euryales*, some good *C. Curtisii*, and hybrid *Selenipediums*. Of other species noteworthy were *Angraecum* *Eichlerianum*, of singular growth, and bearing large flowers with scoop-shaped labellum, green at the base, and white in front; *Oncidium* *spilopterum*, some gr. *celu* *O. incurvum*, *O. pretextum*; a singular almost wholly light yellow *O. varicosum*; the pretty scarlet *Renanthera matulina*, a good example of *Aerides Lawrencei*, *Cycnches chlorochilum*, *Catasetum* *Bungerthii*, *Laelia monophylla* with sixteen flowers; *Lycaste lanipes*, *Cattleya bicolor*, *Brassia Lawrenceana longissima* (Botanical Certificate); *Odontoglossum* *Urskinneri splendens*, very bright in colour; and other species. The group, which was a fine one in every respect, was awarded a Silver Flora Medal.

FRED. HARDY, Esq., Tyntesfield, Ashton-on-Mersey (gr. Mr. Thos. Stafford), was awarded a Silver Flora Medal for a small but select group of Orchids, the prominent feature in which was a good example of *Cattleya* × *Hardyana*. With it there were of note *Cypripedium* × *Hardyanum* (× *Ainsworthii* × *caudatum*), much resembling *C. macrochilum*; a fine variety of *Laelio-Cattleya* × *elegans*; *Cattleya* × *Ashtonii*; *C. x polypophlebia*, with pretty light lilac flowers, and purple blotch on the lip; *Dendrobium Phalanopsis* *Echroderanum*, &c.

R. I. MEASURES, Esq., Cambridge Lodge, Camberwell (gr. Mr. H. J. Chapman), showed *Rhynchostylis coelestis*, Cambridge variety, a very handsome form, with bright blue lip, and lighter blue tips to the sepals and petals (Award of Merit); and a *Cattleya Schofieldiana* *superba*, large in size and fine in colour.

THOS. STATTER, Esq., Stand Hall, Whitefield, Manchester (gr. Mr. R. Johnson), showed *Cypripedium* × *Lord Derby* (*Rothschildianum* × *superbians*), which received a First-class Certificate when he first showed it, August 13, 1893, and was well illustrated in the *Gardener's Chronicle*, September 28, 1893, p. 357; also *C. x Lady Isabel* (*Rothschildianum* × *Stoneli*); and the handsome *C. x triumphans* (*Schilleri* *Hyeunum* × *cananthum* *superbum*).

Major JOCKY, Sunningdale Park, Sunningdale, Berks (gr. Mr. Fred J. Thorne), showed a strong plant of the fine old *Acineta Parkeri*, with two pendent spikes of large wax like

yellow flowers, spotted with crimson in the centre. The two spikes bore together forty-five flowers (Botanical Certificate).

Mrs. HARRIS, Lamberhurst, Kent (gr., Mr. Huggins), sent *Cattleya* × *Miss Harris* (C. Mossie × C. Schilleriana), a pretty hybrid, partaking much of C. Schilleriana.

WELCHER S. ELLIS, Esq., Hazelbourne, Dorking (gr., Mr. Bartel), showed *Oncidium panduratum*, a species of the O. Wentworthianum class with brown flowers tipped with light yellow (Botanical Certificate).

A. W. WARBURTON, Esq., Vine House, Haslingden, Manchester (gr., Mr. T. Lofthouse), showed the fine yellow-flowered *Cypripedium insigne* var. *Laura Kimball* with two fine flowers.

C. L. N. INGRAM, Esq., Elstead House, Godalming (gr., Mr. T. W. Bond), sent *Laelia* × *splendens* (crispa × purpurata); and a small form of L. C. × *Andromeda* (bicolor × elegans Turneri) named L. C. × *Gazelle*.

MESSRS. HUGH LOW & CO., Clapton, showed *Cattleya* × *Minnica* (Loddegesii × Warscewiczii), in good form; *Cypripedium* × *Alfred Hollington*, and other *Cypripediums*.

MESSRS. FANDER & CO., St. Albans, sent *Cypripedium* × *callo-Rothschildianum*, C. × *barbatum* × *Rothschildianum*, the pretty *Maxillaria striata*, *Odontoglossum Kramerii* with twenty flowers; the pretty natural hybrid *Miltonia Peetersiana* with dark rose flowers barred with purple; *Miltonia spectabilis* Moreliana, &c.

Fruit Committee.

Present: Philip Crowley, Esq., chairman; and Messrs. Geo. Bunyard, H. W. Ward, G. W. Cummins, T. J. Saltmarsh, A. H. Pearson, J. Wright, C. Herrin, J. W. Bates, W. Farr, W. J. Empson, G. H. Sage, Geo. Wythes, H. Balderson, J. Smith, Geo. Reynolds, and J. Willard.

In the Veitchian competition for flavour, the 1st prize for Apples was taken by Mr. J. MAYNE, Bilton Gardens, Devon, who showed Kerry Pippin, from an espalier tree on the Crab stock. The 2nd prize was awarded to a dish of Gravenstein, shown by Mr. Geo. Wythes, gr. to Earl Percy, Syon House, Brentford. The best Pear was Williams' Bon Chrétien, from Mr. Herrin, gr. at Dropmore, obtained from a bush-tree upon the Quince stock. The same variety from Mr. WYTHES was placed 2nd.

Several good seedling Melons were shown, and to one of these, named Mrs. Herrin, shown by Mr. HERRIN, an Award of Merit was recommended. This was obtained from a cross between La Favourite X, and an unnamed seedling. It has white flesh, uncommonly deep, of good flavour, and very juicy; exterior is straw-coloured, netted, of moderately large size. The cavity in this Melon is very small. Mr. HERRIN also exhibited a fine fruit of Diamond Jubilee Melon, a variety shown at the last Temple Show, when it was given an award.

Mr. Miller, gr. to Lord Foley, Ruxley Lodge, Claygate, exhibited fifteen large, handsome fruits of Princess of Wales Peach for which a Bronze Knightian Medal was awarded. He had also a dish of Yorkshire Beauty Apples, a large, rather flat shaped culinary variety with considerable colour upon one side.

An Award of Merit was recommended to Scarlet Runner Bean, Bunyard's Hill prize, shown by Mr. W. J. EMPSON, Amptill Gardens. The pods were about 10 inches long. Mr. W. MITCHELL, Fir Cottage, Farnham Royal, Slough, exhibited fruits of a Seedling Blackberry, and sprays of same. The fruits were very fine, and this variety free cropping (Award of Merit).

Mr. J. Coles, gr. to H. J. WALKER, Esq., Balcombe, Sussex, obtained a cultural commendation for a dish of beautiful fruits of Exquisite Peach.

Mr. W. KEMP, The Gungah, Barnes, was awarded a Silver Banksian Medal for an exhibit of twenty-four good Melon-fruits, representing several of the finest varieties.

Madresfield Court Grapes in three bunches from C. BAYER, Esq., Forest Hill, gr., Mr. W. Taylor, were deservedly awarded a Cultural Commendation; and a similar honour was deservedly given to a dozen Stirling Castle Peaches shown by Mr. W. Howe, gr. to HENRY TATE, Esq., Streatham Common.

From the Royal Gardens, Windsor, Mr. O. THOMAS exhibited a large number of Peaches and Nectarines, all grown out-of-doors. The varieties were Violette Hâtive, Stirling Castle, Prince of Wales, Alexandra Noblesse, Princess of Wales, Grösse Mignonne, Premier, Buckingham Mignonne, Bellegarde, Barrington, Alexandra Noblesse, Teton de Venus, Hardwick Seedling, Raymaker, Dr. Hogg, Dymond, Condor, and Crimson Galande, Nectarines, Pine-apple, Victoria, Hardwick Seedling, Humboldt, Violette Hâtive, Prince of Wales, Spencer, Lord Napier, and Oldenburg. Some Golden Jubilee Tomatoes shown were perfect in shape, heavy, and of pretty appearance. A Silver-gilt Knightian Medal was deservedly awarded.

A collection of fruits, embracing seventy dishes, was shown by Mr. Geo. WYTHES. The bulk of these were Apples and Pears, many fine dishes of each being noticed. In addition, there were fifteen dishes of Peaches in as many varieties; four Nectarines, viz., Elruge, Dryden, and Humboldt; four varieties of Plums, viz., Pound's Seedling, Archduke, Victoria, and Purple Gage; Shropshire and Cluster Damsons, a dish of Mulberries, and Morello Cherries. The collection was a very praiseworthy one, and a Silver Knightian Medal was awarded.

From JNO. RUSSELL, Esq., Richmond, were some uncommonly well-cropped Tomato plants from out-of-doors; the variety was Campbell's Prolific.

Lecture on Nepenthes.

Mr. HARRY J. VEITCH, who delivered a lecture upon this genus of plants, avoided going over the ground traversed by Professor Vines before a meeting of the Royal Horticultural Society on June 15 last, when the power possessed by *Nepenthes* to decompose and digest in the pitchers various organic bodies was explained and defined. Mr. Veitch commenced by tracing the early history of these interesting plants, and gave particulars as to time and circumstance when many of the typical species were introduced. Until the commencement of the nineteenth century, the known history of the genus is fragmentary to some degree; but afterwards the introduction of the various species can be followed with comparative certainty. Thus Mr. Veitch referred to *N. Rafflesiana* introduced from Singapore in 1815, *N. Hookeriana* from Borneo, in 1847, and many others. A large number of species were introduced between 1880 and 1890. The Seychelles *Nepenthes*, *N. Purvillii*, was illustrated by a plant bearing several pitchers that had been kindly lent by the Director of the Royal Gardens, Kew, who, in an accompanying letter, remarked that it had taken more than a quarter of a century to introduce this species to Britain. Mr. Veitch spoke at some considerable length upon the species obtained from Borneo, and one of these, *Rajah*, which produces a very handsome pitcher, but is very difficult of cultivation in this country, was illustrated by a dried Pitcher from Borneo, and a fresh one that had been produced in the hothouses at the Royal Gardens, Glasnevin, Dublin. Mr. Moore, the skillful director there, had obtained a Pitcher rather more than two-thirds as large as the one produced naturally, and as the achievement is without parallel in the case of this species, Mr. Moore is to be congratulated. Mr. Veitch, when speaking of the plants, in most cases alluded to the specific characters, and with the fresh and dried specimens at his hand, he was able to impart to his hearers a very large amount of interesting information. Passing from a review of the species, to speak of the hybrids that had been obtained by hybridisation in this country, Mr. Veitch said, that though there were probably forty varieties considered hybrids, he thought that many of these were merely varieties from hybrids, and that certainly there had not been that number of crosses effected. There have been ten hybrids raised at Chelsea, already distributed, and Mr. Veitch was enabled to show some of these in comparison with the parents, and to explain what characteristics had been secured in the progeny, that for horticultural purposes made it more valuable than either of its parents. Instancing *N. Mastersiana* and a few others, it was an easy matter to show that some of the very best plants in the genus were hybrids; and Mr. Veitch was on very safe ground when he declared that whilst certain species would always claim a prominent position in gardens, the effect of the work of the hybridist would be that a great number of varieties would be raised that would yield fine pitchers, and combine with this property a strong habit of growth, and eventually, as a race, they would be more useful to the gardener than the original species. This much has already been proved: that the hybrids raised as seedlings in English hot-houses are much more amenable to the artificial culture essential in this climate than are the species. There are some hybrids possessed by the Chelsea firm that have not yet been shown or distributed, and one was before the meeting on Tuesday. It was named *N. Tiveyi*, and is alluded to in the above report.

Next, Mr. Veitch devoted some time to a description of the botanical features of the genus. Some coloured drawings helped greatly to supplement these remarks. The diocious flowers were described, the essential organs, male and female. The processes of pollination and fertilisation were explained, and the time which elapsed between the one and the other given. A few pots of seedlings one year old, and others a little more advanced were shown, and the rate of progress of growth at that stage and subsequently, were matters referred to in detail. The first true leaves produce pitchers, and these become larger on succeeding leaves, in proportion as the strength of the plant increases.

The concluding part of Mr. Veitch's admirable paper was devoted to a description of the habitats of most of the species. The conditions of climate the plants naturally enjoy were given precisely, and statistics of rainfall, temperatures, humidity of atmosphere were given that had been taken from observations made at meteorological stations.

Following the reading of the paper, Mr. F. W. Burbidge, M.A., Curator of the Botanical Gardens at Trinity College, Dublin, remarked upon the subject under discussion at considerable length. He first referred to the Pitchers themselves, and reminded the audience of the insect-digesting powers they had, suggesting that Nature had prompted the plants to develop this means of obtaining nourishment in order to compensate for the disadvantages attending a weak root-system. Passing, Mr. Burbidge had something interesting to say about the Bornean species at home, and of his experience when collecting some of them in company with Mr. Peter Veitch. From personal observation, too, Mr. Burbidge described the white mist that is peculiar to great altitudes in Borneo, and how all vegetation in this zone is continually wet, and the temperature cooler, but unusually even. Cultivators in this country had to produce circumstances as nearly like these as possible. In an ordinary *Nepenthes*-house (Mr. Burbidge reminded his hearers) air should be allowed to enter the house from the bottom, but that no top ventilation should be open at the same time. A better system Mr. Burbidge thought would be to build a structure for the *Nepenthes* without any special means of heating it; surround this with the hottest of the stoves, and by allowing the air to pass from these into the cooler atmosphere of the *Nepenthes*-house a condensation of moisture would occur as nearly as possible resembling the natural state of things.

READING HORTICULTURAL

SEPTEMBER 1.—Nothing is more depressing than a show held during a gale, accompanied by drenching and it was under such circumstances the usual summer of this Society took place. As usual, the display was in the Abbey ruins, and the tent covering being shaped, quite a deluge of water came through at points. The weather kept visitors away, and a great must result. This was all the more to be regretted, generally a good exhibition; some of the fruit, vegetables especially, being superb.

PLANTS.—Stove and greenhouse plants were all eight, the 1st prize being taken by Mr. W. FINK, O. Mr. Chamberlain, gr. to F. M. LONERGAN, Esq., Cres Park, took the 1st prize with four specimens. 1 specimen plant in flower was *Erica Marnockiana*, 1 Peel, gr. to Miss Todd, Shirley, Southampton; Mr. gr. to J. B. KANSLAKE, Esq., Whiteknights, coming 2 a superbly-grown and flowered light-flowered *Fuchsia Western Beauty*. Orchids were poorly shown, but better is late for them. *Fuchsias* were shown by Mr. large, finely-grown pyramids, admirably blooming, Wilson, gr. to Mr. B. GARLAND, Lower Redland, 1 *Lilium*, double zonal *Polargonium*, and tuberous were not exceptional. In the amateurs' divisions, staged in fours made a good show, Mr. Smith, gr. NIELD, Reading, taking the 1st prize.

Stove and greenhouse Ferns were well shown Willis, gr. to H. C. SIMMONDS, Esq., Reading, who excellent specimen of *Microlepia birta cristata*, also *phila australis*, *Cibotium princeps*, &c. Mr. Leith A. R. WELCH THORNTON, Esq., Basingstoke, was 2nd latter had the best four fine-foliaged plants, having coloured piece of *Croton Queen Victoria* among them.

Mr. PEEL had the best three Palms, staging 3 examples, consisting of two fine *Kentias*, and a *Lat. bonica*. Mr. G. LEWIS was 2nd. *Coleus* were also the best of them in the form of bright-foliaged pyramids.

GROUPS.—One extremely interesting feature at the exhibition was the competition in the large group class 180 feet, arranged on the turf banks in the Abbey ruins were four competitors, there being offered by Messrs. & Sons a very handsome chased Silver Cup of the 25 guineas, which is held for a year by the holder, addition a cash prize of £5. This was won by Mr. 1 to Miss Todd, with a very tasteful arrangement, in usual subjects were grouped in a skillful manner. has to be won three times in succession before it can outright. Mr. Pope, gr. to J. P. WHITE, Esq., Wargrave 2nd. There were several competitors with small group 180 feet, Mr. CHAMBERLAIN taking the 1st prize.

CUT FLOWERS.—Among the cut flowers Dahlias took The best eighteen blooms came from Mr. J. WALKER, run very close by Mr. S. MORTIMER, Farnham, who both stands contained excellent blooms. Mr. J. R. T. Henley-on-Thames, had the best twelve bunches, as SUCH, Maidenhead, was 2nd. The best six bloom amateur division came from Mr. G. LEWIS. Messrs. & Sons, Crawley, had the best twelve bunches of flowered, among them *Duchess of Marlborough*, white with crimson-purple, was very striking. Mr. MORT the best eighteen blooms of *Cactus Dahlias*. Mr. W had the best twelve, and was also 1st with the same of Tea Roses; but storms had affected them. In the class of twelve, W. C. ROMAINE, Esq., Windsor, was

MESSRS. J. CHEAL & SONS had the best twelve *Glaudiolus*; MESSRS. WALLACE, Colchester, was 2nd FINCH had the best twelve bunches of cut flowers, mainly stove and greenhouse subjects.

FRUIT.—In the class for eight dishes of fruit prize went to Mr. Gleeson, gr. to C. E. KEYS Warren House, Stanmore, who had finely-finished Muscat and Black Hamburg Grapes, both showing lent culture; a grand Smooth Cayenne Pine-apple Turkey Figs, Pittaston Nectarine, Barrington extra fine in size and colour; Golden Gem M. splendid Morello Cherries. Mr. POPE was 1st Muscats, Smooth Cayenne Pine, and Favourite 1 good.

With six dishes, Mr. Howard, gr. to Mrs. MET ham Park, was 1st, with fine Pine-apple Nectarine Castle Peaches, and good Grapes; Mr. CHAMBER the 2nd prize. Mr. W. Fyfe, gr. to Lord WASTAGE Park, was very successful with Grapes, showing examples. He was 1st with three bunches of Bl burgh, also with any other black variety, and w Muscats. In the latter class, Mr. Cole, gr. to Sir G. Bart., Swallowfield Park, had three large w bunches, but the berries were rather small. The r in upon Peaches, Nectarines, Apricots and Plum Ross, gr. to Captain A. J. CARSTAIRS, Welford Park, had the three best dishes of culinary Apples; Mr. Benham, was 2nd. Mr. TURTON, Maiden Erlegh three best dishes of culinary Pears. Dessert Peas &c., were shown; also Cucumbers, as near per shape and size as could well be imagined.

VEGETABLES.—The handsome money-prizes given SUTTON & SONS for twelve distinct kinds of brought thirty-seven collections. Seven prizes were Mr. R. LYE, The Gardens, Sydnonton Court, New the 1st prize with a collection so perfect as to be desired. Mr. BOWERMAN, The Gardens, Hack

Basingstoke, was 2nd. These collections, the first seven or eight of which were of high quality, made an exhibition in themselves. Mr. NICHOLLS, The Gardener, Malshanger, Basingstoke, took the 1st of Messrs. WOOD & SONS' prizes for his kinds; and Mr. JOHNSON gr. to A. GILLIAT, Esq., was 2nd.

MISCELLANEOUS.—Fine and showy miscellaneous collections of cut flowers, &c., were shown by Messrs. JAMES VERN & SONS, Chelsea, J. LAING & SONS, Forest Hill, WILKINSON & CO., of Colchester, and others.

GLASGOW AND WEST OF SCOTLAND HORTICULTURAL.

SEPTEMBER 1.—One of the best displays of fruits, flowers, and vegetables ever seen in the western capital of Scotland was made on the above date. At the main entrance were large exhibits of cut flowers from several nurseries; and plants and flowers from Mr. M. CUTHBERTSON of Rothesay filled a large space. Blooms of herbaceous plants were strongly in evidence, and interspersed with florist flowers of brilliant colour, they made a great display. Mr. FORBES of Pawick had large collections of hardy flowers and Carnations; and a large and choice collection of Dahlias and Pansies was shown by Mr. T. SMELLIE.

Messrs. DOBIE & CO., of Rothesay, had a table 45 feet long furnished with products from their Rothesay grounds. Their Pansies were very fine, and there was an immense collection of all classes of Dahlias. Spikes of stately Hollyhocks backed up this large exhibit. An exhibit from Mr. CAMPBELL, High Blawithie, contained many Dahlias and Carnations.

Roses were of much excellence, and Mr. CROLL, of Dundee, obtained the 1st prize for twenty-four blooms. Messrs. CARR of Aberdeen, were 2nd, with a handsome exhibit.

Dahlias made a considerable display, and many growers competed well in the various classes. Mr. CAMPBELL of Blawithie was 1st for the larger collection; and Mr. SMELLIE, of Marigolds, Asters, Pansies, and Antirrhinums of good quality were present in quantity.

In the larger hall, tables of plants for exhibition were not so numerous as on some former occasions. Messrs. SMITH & SONS had a large exhibit of choice foliage and flowering plants, and Messrs. AUSTIN and McALAN had a fine display of plants on and in front of the large platform.

Mr. D. WILSON, gr. to Mr. STEPHENS, Westmount, was 1st, showing a table of beautiful plants, including Odontoglossums and other Orchids. The 2nd prize was taken by Mr. MILLER, gardener at Auchensalth.

A large table filled with bouquets in great variety was the centre of much admiration.

Table plants were numerous, and the competition in the class for six specimens was keen.

Fruit generally was remarkably good, especially black Grapes; Muscats, too, were well shown, and some of them were finely coloured. Apples, Pears, and Plums were less numerously shown than usual. Mr. D. MURRAY, gr. to the Marquis of Ailes, Culzean Castle, was the only exhibitor in the class for a collection of twelve sorts. He had a remarkably handsome Queen Pine, capital Nectarines, Brown Turkey Figs, Best of All Melon, and good Grapes, but we have seen Mr. MURRAY's Grapes much finer than they were this season. Mr. AIRDRIE, Lurbert House Gardens, was 1st for six dishes; his Black Hamburg Grapes, Sea Eagle Peaches, Pine-apple Nectarines, and Figs were first-rate. Mr. BURMAN, gr. at Bargany, was a good 2nd, but some of the fruits were past their best.

The tempting prize for four bunches of Grapes was carried off by Mr. AIRDRIE, beating Mr. LEALIE, of Pitruillen, who has never before been beaten in this class at Glasgow. Mr. AIRDRIE's bunches were Muscat Hamburg, Moscat of Alexandria, Madresfield Court, and Black Hamburg, large in bunch and berry, and highly finished; Mr. LEALIE had fine Muscats of Alexandria.

Fifteen bunches were tabled in the class for Black Hamburgs. Mr. MENZIES, gr. at Drumleopard (?), was 1st, with a grand pair of bunches; Mr. AIRDRIE, Lurbert, was a close 2nd.

Mr. LEALIE's 1st prize pair of Muscats of Alexandria were remarkably fine; Mr. AIRDRIE was 2nd with well-coloured bunches.

The other classes for Grapes were well contested, and that for the heaviest bunch was won by Mr. LEALIE, who staged one weighing 8 lb.

Apples were not remarkable for size or quality; neither were Pears. Peaches, though not numerous, were fine in size and colour. Mr. AIRDRIE was 1st with Sea Eagle. Nectarines were very fine especially the 1st prize exhibit of the variety Pineapple from Mr. MURRAY.

A large hall was crowded with vegetables of fine quality. Mr. BROWN, gr. at Houston, had a capital collection; Leeks, Celery, Peas, and Potatoes being as fine as they are ever likely to be seen at a September show. Potatoes were remarkably well exhibited, and were, without exception, clean and of fine form. The exhibits from amateurs were numerous and good.

NATIONAL DAHLIA.

SEPTEMBER 3, 4.—The annual exhibition of this Society was held on the above dates, at the Crystal Palace. In face of the unusually severe gales of the forepart of last week, Dahlia growers had not anticipations of a record show, for

each of them was painfully aware of the difficulty attending the preservation of their own flowers from the effect of wind and rain. We do not intend to speak of the exhibition in the superlative degree but there can be no hesitation in describing it as very satisfactory, and much beyond general expectation. No doubt, the strongest section was that of the Cactus-like flowers; there was much competition in the classes, and the flowers were decidedly good. Indeed, such a bank of Cactus blooms as was produced by the classes for eighteen and twelve varieties has seldom, if ever, been staged. From an exhibition point of view, the section next popular was the show type—the large, symmetrical, "spat" looking flowers, as if chiselled, but possessing colours of beautiful and varied shades. Too solidly heavy to cut for decorative purposes, they seem to be cultivated for the exhibition boards alone. The decorative flowers were few, and they are merely a compromise between the show and Cactus types. Pompons are useful for decoration, and they are most effective in the flower-borders. There were several exhibitors in these classes, which we think it would be more pleasing were greater care to be used in the selection of the smallest most "Pompon" like flowers. Single flowers, the petals of a dozen years ago, are partially neglected, and it is easily seen that the circumstance is due to the marvellous development in the Cactus section. The few exhibits of single flowers, however, were so good as to suggest, "Why has our popularity decreased?" Single flowers with longitudinally recurved petals, and describe a single-flowered Cactus, do not appear to find much favour unless with persons who admire an æsthetic kind of decoration.

Many new varieties of Dahlias were submitted for Certificate; and, as usual, these were principally of the most popular sections. One of the very best was the Cactus bloom shown by Mr. WEST, and named Island Queen, a pure mauve-coloured flower, and distinct from any hitherto raised.

COMMEMORATION CLASS.

The principal class at this Exhibition was one known as the Commemoration Class, in which tempting prizes were offered for the best decorative display of Dahlia blossoms, together with ornamental foliage plants, &c. These groups were staged on a table-space of 13 feet by 6 feet, and were intended to advantageously display the development that has taken place in the Dahlia during the Victorian Era.

As a matter of fact, the exhibits were decorative arrangements of Dahlia blooms, and nothing more. The Victorian Era was only suggested by the collection awarded 1st prize, and this suggestion consisted in a rather stiff-looking crown composed of a yellow Pompon Dahlia, and by the monogram V.R. with 1837 on one side, and 1837 on the other, all in Dahlia blooms. In a group arranged for effect, it would have been dangerous to have sought by comparison to demonstrate the development that has taken place, and the task was not attempted. Apart from this failure to comply with the schedule, the two collections were satisfactory. As pictures, the 2nd prize collection was the more enjoyable, but it did not thrust the Dahlia forward so well and thoroughly as in Mr. M. V. SEALE's collection from Sevenoaks. Few plants were used in the latter exhibit, and there was a profusion of cut blooms, in sprays, upon pillars, and as shower bouquets, and it probably deserved the 1st prize awarded to it. Messrs. J. CHEAL & SONS, Crawley, employed much fewer flowers, and they were well toned down by a profusion of suitable foliage. A cone, with a Palm-capped top, was the least pleasant feature in this stand.

SHOW AND FANCY BLOOMS INTERMIXED.

There were five collections in the class for sixty blooms, and it was an exhibit of considerable merit that won the 1st prize for Messrs. KEYNES, WILLIAMS & CO., Salisbury. We will give the varieties as being of interest in this noteworthy year:—Back row: W. Rawlings, Emin Pacha (very fine bloom), Harrison Weir, J. T. West, R. Dean, Mr. Chamberlain, M. Campbell, Chieftain, Duchess of Albany, Mrs. C. Noyes, Harry Keith, Rev. J. B. Camm (sport), a distinct coloured flower; Duke of Fife, Dorothy, Colonel, Geo. Birnes (self), J. Hickling, beautiful soft yellow; A. Ocock, Pelican, and Gaiety (sport). Centre row: Buffalo Bill (dark crimson self), Florence Tranter, Imperial, Royal Queen, Rev. J. B. Camm, Comte de la Saxe, R. T. Rawlings, Nellie Cammel, Mrs. Saunders, Alice, Emily, Gaiety, curious markings of red, yellow, and white; Thomas Hobbs, William Powell, yellow; Arthur Rawlings, Virginal, Buffalo Bill, Miss Barber, H. Walton, Mr. Glascock, and Duchess of York. Front row: Niblan, Mrs. Langtry, Miss Cannell, W. Keith, Mrs. Every, Mrs. McKenzie, Dazzler, T. S. Ware, Mrs. W. Slack, Seedling Yellow with reddish edges, H. Bond, Mr. Spoforth, Hon. P. Wyndham, Shott's-ham Hero, Goldsmith (yellow sport, with deep red margins), Mrs. Morgan, Golden Pledge, Kathleen (very pretty tint), Rebecca (self), and Mrs. Gladstone. The colours might have been more effectively disposed in this stand. Mr. CHAS. TURNER, Royal Nurseries, Slough, was 2nd, with an even lot of medium-sized blooms, of good colours, and well put up.

In the class for forty-eight blooms, distinct, there were again five exhibitors, the chief honour being won by Mr. J. WALKER, Thame, Oxon. We noticed in this stand of praiseworthy blooms, excellent examples of Chorister, John Hickling, Jno. Standish, Victor, Harrison Weir, H. Walton,

Dorothy, Eclipse, Perfection, Glow-worm, one of the brightest of Dahlias; Peacock, Maud Fellow, Emin Pacha, and others; Mr. C. TURVER, again showing smaller, well-formed blooms, was 2nd; and Mr. S. MORTIMER, Rowledge, Farnham, was 3rd, exhibiting commendable blooms.

Of thirty-six blooms, distinct, there were only three collections, and the 1st prize was taken by Mr. G. W. HUMPHRIES, Twickenham, with an exhibit of capital blooms of moderate size; Mr. J. WEST, Tower Hill, Brentwood, was 2nd; and Mr. J. BRECKWICK, St. Leonards-on-Sea, 3rd.

Mr. G. W. HUMPHRIES won the class for twenty-four blooms with a collection containing fine specimens of Colonel, Jas. Stephens, Mrs. Sanders, Mrs. John Dawkins, Harry Keith, W. Powell, Mrs. Gladstone, and others. The only other exhibitor in this class was Mr. J. WEST, Tower Hill, Brentwood, whose blooms were a little below good exhibition size.

The best exhibit of twelve blooms was from J. R. TRANTER, Esq., Henley-on-Thames, who had Chieftain, Duke of Fife, Florence Tranter (fine bloom), Jas. Cocker, Duchess of York and Miss Cannell (both pretty edged blooms), Shirley H. B. R. T. Rawlings, Rosamond, Mrs. Langtry, Arthur Rawlings, and Matthew Campbell; Mr. A. RAWLINGS, Romford, was 2nd; and Messrs. J. CHEAL & SONS, Crawley, 3rd.

Cactus blooms.—These were the feature of the show, and elicited general admiration. There were seven competitors in the class for eighteen varieties in bunches of six blooms each, and in a marvellously keen competition the 1st prize was gained by Messrs. J. BURRILL & CO., Howe House Nurseries, Cambridge. The varieties staged were Mrs. A. Beck, Falsa, a soft purplish-red coloured flower; Mrs. Wilson Noble, rather less deep in colour than we have seen this comparatively new variety; Lady Penzance, a charming yellow flower; Mrs. F. Fell, white; Earl of Pembroke, purple; Gloriosa, Delicata, a most beautiful bloom; Chas. Woodbridge, Harmony, Fusilier, Fantasy, with crab-apple-like petals; Mrs. Kingsley Foster, Matchless, Casilda, Starfish, excellent scarlet variety; Cinderella, and Hagulus, a deep crimson self of excellent quality, and awarded the Society's First-class Certificate. Messrs. KEYNES, WILLIAMS & CO., Salisbury, took the 2nd prize, an enviable one in such a competition. This firm included several new varieties, such as Mary Service, Stella (scarlet, crimson), Alfred Vasey (salmon red), Ruby (crimson and purple), and Archino, a bizarre-looking flower with much recurved petals (white and red, centre of each petal white). Messrs. J. CHEAL & SONS were 3rd, and included a few new ones also, notably, King of Siam, a deeply-coloured flower, the inner petals of which are almost black.

Mr. J. WEST was the winner of the 1st prize for a collection of twelve varieties, beating Mr. G. W. HUMPHRIES, 2nd; and Mr. S. MORTIMER, Farnham, 3rd. In Mr. West's stand was a pure mauve-coloured variety named Island Queen, and awarded the Society's First-class Certificate. There were several seedlings of some merit, J. C. Drower and Eileen Palliser were very fine blooms. Two 2nd and 3rd place collections were very good.

Decorative Varieties.—There were three exhibitors in a class for twelve varieties, in sprays of six blooms each. The 1st prize was taken by Mr. M. V. SEALE, Sevenoaks. The collections made a pretty offset. Messrs. J. CHEAL & SONS were 2nd, and Mr. JNO. CHARLTON, Tunbridge Wells, 3rd, each staging commendable exhibits.

Pompons.—The largest class in this section is for twenty-four varieties, and they are shown in sprays of ten blooms each. Messrs. KEYNES, WILLIAMS & CO. were 1st, with a praiseworthy lot of blooms, inclusive of a seedling under the name of Agate, pale lemon in colour, very slightly marked with pale purple. The other varieties call for no special remark. The 2nd prize was awarded to a collection from Messrs. J. CHEAL & SONS, which appeared to run very closely the exhibit just noticed. The blooms were good, and in addition to being fairly representative, they were set up very neatly; Mr. C. TURNER, Slough, was 3rd, and showed several novelties, including Ida, yellow, with crimson edge; Snowflake, white; and Hypatia, pale red, with yellow centre. There were four competitors.

The class for twelve blooms was won by Messrs. J. BURRILL & CO., with a praiseworthy exhibit of the choicest varieties. Mr. J. WEST was a good 2nd, and obtained a First-class Certificate for the variety Nellie Broomhead, exhibited in this collection. It is of capital form, and the colour is very pretty mauve. Mr. G. H. HUMPHRIES was 3rd.

Single flowered Varieties.—Messrs. J. CHEAL & SONS, Crawley, were 1st in the class for twenty-four varieties, and they were shown similarly to the Pompons in bunches or sprays of ten blooms each. The stand was a good one, and well calculated to display the charms of the single-flowered section. The 2nd prize was taken by Mr. M. V. SEALE, who is also entitled to a share of praise.

The class for twelve varieties found but one exhibitor, viz., Mr. J. WALKER, Thame, Oxon, who had a stand of capital blooms, staging the following varieties: Miss Roberts, Northern Star, Amos Perry, Mude, W. C. Harvey, Formosa, Duchess of Westminster, Victoria, Lowfield Beauty, Mrs. Bowman, and Eclipse.

AMATEURS.

The classes for amateurs were well filled, and the number of exhibitors in this division is on the increase. The best twenty-four blooms of show and fancy varieties, came from Mr. THOMAS HOBBS, Lower Easton, Bristol, a veteran who commenced to exhibit in 1852, and on this occasion headed the nine other competitors. He had well-finished blooms of

Duchess of York. Vice President, John Hickling, Matthew Campbell, Imperial, Mrs. Gladstone, Mr. W. Slack, Thomas Hobbs, Muriel Hobbs (new), Prince of Denmark, &c. Mr. A. STARLING, Havering, Romford, was 2nd. Mr. S. COOPER, Chippenham, had the best twelve show varieties; and Mr. W. MIST, Igham, was 2nd. Mr. C. KEEP, Streatham, came in 1st with the best six, and Mr. G. WYATT was 2nd.

In the amateurs' division, fancy Dahlias are still shown by themselves. Mr. S. COOPER took the 1st prize with twelve, having, in good character, Frank Pearce, Mr. J. Down's, Mr. Saunders, Sunset, Matthew Campbell, Lottie Eckford, &c. Mr. R. BURGIN, St. Neots, was 2nd. Mr. A. STARLING was 1st with six blooms, having the Rev. J. B. M. CAMIN, S. Mortimer, Peacock, Duchess of Albany, S. Cooper, and Dazzler. Mr. E. JEFFRIES, Langley Burrell, was 2nd. There was a class also for maiden growers, which brought a good competition.

The amateurs made a good display with Cactus varieties. Mr. W. MIST taking the 1st prize for twelve bunches of six blooms; chief among them being Starfish, Mr. Wilson Noble, Mr. A. Beck, Miss A. Nightingale, Masterpiece, and Gloriosa. Mr. E. BROWN, Horley, was 2nd.

The best six bunches were shown by Mr. E. MAWLEY, Berkhamsted; Mr. C. E. WILKINS, Swanley Junction, 2nd. Messrs. J. CHEAL & SONS offered prizes for nine bunches, the best coming from Mr. WILKINS, who had Mr. Wilson Noble, Lady Penzance, Fusilier, and Charles Woodbridge, the latter being very fine this season. Mr. H. A. NEEDS, Horsell, was 2nd. In the Maiden class for six bunches, Mr. F. SHARP, Twyford, took the 1st prize.

The best six varieties of Pompon Dahlias were shown by Mr. W. C. PAGRAM, Weybridge, chief among them were White Aster, Arthur West, Phoebe, and Sunshine; Mr. J. HUDSON was 2nd.

Mr. E. JEFFRIES had the best six varieties, six blooms of each; Mr. G. WYATT was 2nd.

Mr. T. W. GIRDLESTONE, Sunningdale, took a 1st prize with six bunches of ten blooms of single Dahlias, having attractive varieties in Cadet, Naomi, Tighe, Jeannette, Polly Eccles, Phyllis, and Fred. Leslie. Mr. C. OSMAN was 2nd.

Mr. E. MAWLEY had the best six bunches of six blooms, Beauty's Eye, Demon, and Miss Roberts being his best; Mr. J. HUDSON was 2nd.

Mr. J. HUDSON took the 1st of Messrs. DOBBIE & Co.'s special prizes for six single Cactus Dahlias; and Mr. C. OSMAN was 2nd.

OPEN CLASSES.

The series of classes for six blooms of one colour of Show and Fancy Dahlias is useful as bringing out the best of each. Thus, the best dark was the Prince of Denmark, from Mr. M. W. SEALE, Shirley Hibberd, and William Rawlings following. We do not appear to have any light Dahlia which can beat Mrs. Gladstone—it was 1st, 2nd, and 3rd, Mr. MORTIMER having the best. The leading yellow self was John Hickling, from Mr. MORTIMER, J. N. Keynes, and R. T. Rawling following in order. A bright self-form of the Fancy Mrs. J. Downie, won the 1st prize for a red Dahlia for Mr. MORTIMER, John Standish and Arthur Rawlings being 2nd and 3rd. The best white was John Walker from Mr. WALKER, which when at its best no other white self can compete with. Mr. G. HUMPHRIES had the best tipped Dahlia in Mrs. Saunders, and it took the 2nd prize also. Mr. SEALE had the best striped in Mrs. Downie, and it was 2nd also. The best edged Dahlia was Miss Cannell, from Mr. J. WALKER; J. T. West came next in merit.

NEW DAHLIAS.

Certificates of merit were awarded to Messrs. J. BURRELL & Co., Cambridge, for Cactus Dahlia *Regulus*, deep shaded crimson, a flower of fine shape. To Mr. F. BONNY, for single Dahlia *Colton Beauty*, the sides of the petals edged with soft yellow, very chaste and pleasing. To Messrs. KEYNES & Co., Salisbury, for Cactus Dahlia *Alfred Vasey*, brilliant orange-salmon, flushed with rose on the points of the florets; Mary Service, the base golden-salmon, the points of the florets rose-mauve; Capstan, salmon, suffused with red; and Arachne, the curious tubular florets, white, margined with reddish crimson, and incurving towards the centre—all very fine. To Mr. J. R. TRANTER, for show Dahlia *J. R. Tranter*, a pale orange self, of fine outline, and somewhat distinct in colour. To Mr. C. TURNER, for Pompon Dahlia *Hypatia*, bright terra-cotta, with golden centre—very pleasing. To Mr. J. STREDWICK, St. Leonard's, for Cactus Dahlia *Daffodil*, soft yellow, of exquisite tint and shape; Tillie, salmon, suffused with pale rose, the florets tinged with a ft mauve; and Night, rich maroon, tinted with fiery-crimson towards the edges of the petals—all very fine quality. To Mr. T. HOBBS, for show Dahlia *Muriel Hobbs*, clear, soft yellow, of fine shape and centre. To Mr. S. MORTIMER, for Cactus Dahlia *E. J. Deal*, clear, bright scarlet—very fine. To Mr. G. HUMPHRIES, for Cactus Dahlia *Andie Turner*, orange-red, with a pale cerise shading. To Mr. J. T. WEST, for Cactus Dahlia *Island Queen*, a ft lilac-mauve—very distinct and pleasing; and to Pompon Dahlia *Nellie Broomhead*, soft lilac, of fine shape. To Mr. T. W. FELLOWES, for show Dahlia *Mrs. William Fellowes*, yellow ground, heavily suffused with orange-red, fine petal and shape; and to Mr. GEO. ST. PIERRE HARRIS, for show Dahlia *Harbinger*, soft pinkish-rose—a very attractive shade.

MISCELLANEOUS EXHIBITS.

Messrs. H. CANNELL & Co., Swanley, made a fine display of Dahlia blooms, and a few other flowers. Dahlias were shown by Messrs. CARTER, PAGE & Co., London Wall, and Mr. T. S. WARE, Hale Farm Nurseries, near Tottenham,

and Messrs. J. PEED & SONS, Roupell Park Nurseries, Norwood.

Autumn Roses made an exhibit of some dimensions from Messrs. W. PAUL & SONS, Waltham Cross, Herts. Many of the newer varieties were included, such as Queen Mab, Empress Alexandra of Russia, Waltham Standard, H.P., Enchantress, &c. These varieties appear to afford a considerable amount of bloom during August and September.

Messrs. JNO. LAING & SON, Forest Hill, London, S.E., had a group of plants displaying their Begonias, Caladiums, and Gloxinias. Messrs. A. W. YOUNG & Co., Stevenage Nurseries, showed blooms of Asters, Lilies, and other border plants; and Mr. CHARLTON, Tunbridge Wells, exhibited a group of lard flowers.

NATIONAL CHRYSANTHEMUM.

SEPTEMBER 7, 8, 9.—The usual September show of this Society was held in the Royal Aquarium, Westminster, on the above dates. There was the customary display of Dahlias and Gladioli, but not many Chrysanthemums. Apart from varieties of Madame C. Desgranges, there was scarcely a large-flowered Chrysanthemum well represented in the few competitive classes, which were easily accommodated upon one table. Chrysanthemum plants in flower were commendably shown by Mr. J. H. WITTY, Nunhead Cemetery, and H. J. JONES, Ryecroft Nursery, Lewisham. If Chrysanthemums were unusually attractive, the show of Dahlias and Gladioli left nothing to be desired in the matter of display. Both flowers were well shown. Messrs. J. BURRELL & Co., Howe House Nurseries, Cambridge, with a magnificent collection of varieties, took 1st prize for a collection of Gladioli, and a much smaller exhibit of a similar character was made by Messrs. HARKNESS & SOX, Bedale, Yorkshire.

CHRYSANTHEMUMS.—The first class calls for twenty-four bunches of Chrysanthemums in eighteen varieties, but there was only one exhibitor, viz., Mr. ERIC F. SUCH, nurseryman, Maidentoad. The well-known early-flowering varieties constituted this collection, and we did not notice any new one that calls for remark.

The best twelve blooms of Madame C. Desgranges were shown by Mr. B. CALVERT, gr. to Col. A. HOEBLON, Hallingbury Place, Bishop's Stortford, who had very good blooms of this variety. Little inferior, however, was a dozen from Mr. CHAS. CROOKS, gr. to the Dowager Lady HINDLE, Hudson House, Droitwich; and a third exhibit was staged by Mr. W. PERRIN, gr. to C. W. RICHARDSON, Esq., Fairgreen House, Sawbridge-gate.

Mr. CALVERT took 1st prize for the best twelve blooms or a large-flowering variety other than Madame Desgranges, showing very fine blooms of the yellow-flowering sport *George Wernig*. Extra prizes were given to Mr. W. J. GODFREY, Exmouth Nurseries, and Mr. JAS. AGATE, Havant, both of whom showed twelve blooms, which included several mid-season varieties being contrary to schedule. Emily Silsbury, Queen of the Earlies, and Barbara Forbes, were good in Mr. GODFREY's stand.

The best twelve bunches of Pompons were from Mr. E. F. SUCH; and Miss DEBENHAM, St. Peters, St. Albans, was 2nd. Mr. B. CALVERT had 1st prize for the best six bunches of any yellow variety of Madame C. Desgranges, staging, however, the two varieties *Geo. Wernig* and *Mrs. Hawkins*.

The only exhibitor of six blooms, distinct, who made a tolerable display was Mr. W. J. GODFREY. Emily Silsbury, Lady Father Smith, and Milano being the best varieties.

Miss DEBENHAM beat Mr. D. B. CRANE in a class for twelve bunches of Chrysanthemums.

Mr. B. CALVERT obtained a 1st prize for six blooms of any large-flowering variety, showing Madame C. Desgranges; Miss DEBENHAM was 2nd.

The best epergne of Chrysanthemum blooms was a satisfactory one from Mr. T. S. WILLIAMS, 4, Oxford Road, Ealing.

Of non-competitive exhibits of Chrysanthemums we noticed the following:—Mr. W. WELLS, Earlswood Nurseries, Redhill, furnished a table with bunches of Chrysanthemums of many varieties. The exhibit was remarkable for a really large flower of Madame Gustave Henry, a white-flowered Japanese variety. Mr. J. H. WITTY, Nunhead Cemetery, had an excellent group of plants in flower. For the season they were well flowered, and the group was nicely put up. Mr. H. J. JONES, Lewisham, showed a group of plants in flower, with a smaller group of Begonias at either end. The Chrysanthemums had interspersed among them a few plants of *Lilium sp. solum* album in flower, and the group generally was an exhibit of good taste.

Messrs. H. CANNELL & SONS, Swanley, put up a few bunches of Chrysanthemum blooms, with sprays of *C. perus-grass*; and Mr. NORMAN DAVIS, Framfield, Sussex, had a few varieties of Chrysanthemums, of which Queen of the Earlies, Harvest Home, and Mme. Desgranges appeared to be the best.

DAHLIAS.—We have already described the show of Dahlias as satisfactory, and our space will not permit us to note fully the competitive classes. Some of the principal of these were won as follows: For forty-eight blooms of Show and Fancy Dahlias in thirty-six varieties, Mr. JNO. WALKER, Thame, Oxon, was 1st; and for thirty-six blooms, distinct, Mr. S. MORTIMER, Rowlledge Nurseries, Parnham. Mr. S. HUMPHRIES, Kingston Langley, Chippenham, Wilts, was 1st for twenty-four blooms, distinct, in class 15; and for a similar number in class 17, THOS. HOBBS, Esq., Easton House, Easton, Bristol. Messrs. J. BURRELL & Co. had the best collection of eighteen bunches of Cactus

Dahlias; and Mr. J. T. WEST, Tower Hill, Br had best collection of twelve bunches.

Messrs. KEYNES, WILLIAMS & Co., Salisbury twenty-four bunches of Pompons, distinct; at BURRELL & Co. for twelve bunches.

The best twelve bunches of single-flowered from Mr. ERIC F. SUCH, Maidentoad; but F. STONE, Esq., Sunningdale, won the larger class for four bunches.

Among miscellaneous exhibits, Mr. E. F. SUCH number of Dahlia blooms and hardy flowers. Reid, Beckenham, furnished a table with flow of Cannas. Mr. M. V. SNAKE, Sevenoaks, exhib blooms; and Mr. JNO. GREEN, Norfolk Nurseries made one of the best displays with the same flower.

Mr. THOS. S. WARE, Hale Farm Nurseries, covered a considerable floor-space with a design large central cone of blooms, and smaller cones at A large number of Dahlia blooms were used in which created considerable display.

Apples and Pears were shown by Messrs. S. SONS, Hounslow.

ROYAL CALEDONIAN INTERNATIONAL CULTURAL.

SEPTEMBER 8, 9.—The autumn show of the donian Horticultural Society was held in the Market, Edinburgh, on the above dates. The show was in a flourishing condition. Its finances are good, increasing, and its influence among horticult north is becoming more and more general. This is being held as we go to press is the latest and success that attends the society's efforts.

It is very much with societies as with in stand still is to go back. No increase substantially decrease; and all horticulturists North and South hope that its approaching centenary may but its vigour and augment its vitality. No doubt the Jubilee has added to the prosperity of the show but those liberal prizes have hardly added score to the entries. The growth of the Society regular and steady national advance in horticulture.

To give some idea of the extent of the exhibit be stated that about 360 bunches of Grapes there were five fine fruit tables in one class, containing twenty-five dishes of fruit. There collections of eight dishes of fruit, six or twelve dishes of hardy fruits, four collections dishes of fruits grown in an orchard house, up Melons, nine dishes of Figs each containing t and fourteen dishes of Peaches, twelve fruits The entries were numerous in the classes for culinary Plums, and for Gages. There were s of Apples in the class for twelve varieties; and competition generally in the Apple classes, by lections and in the single dishes, was satisf being staged, at the most moderate calculation 3000 fruits.

The most popular varieties of Apples, as measured number of entries, are Lord Suffield, twenty-one; Castle, twenty-five; Ecklinville, sixteen; King of fourteen; Cox's Orange Pippin, twelve; Rib twelve; Keswick Codlin, fifteen; Irish Pear Warner's King, twelve; Hawthorned, eleven Pearmain, nine; Lane's Prince Albert, nine; Peasgood's, eight; Pott's Seedling, nine; Th nine; Oslin Pippin, eight.

The entries for a single dish of Pears, of six numbered 136, making a total of 514 single fruit alone—not bad for the capricious crop of the ye figures do not include the collections of Pear varieties, four of each, for which there were petitors; and the collection of Pears grown in 1 varieties, four of each. The Jargonelle still hold the most popular Pear, with fourteen entries; V Chretien, 11; Marie Louise, 11; Louise Bonne o Beurre d'Amanlis, 8; Doyenné du Comice, 6; Souvenir du Congrès, 5. There were 20 dish berri s, 19 of Cherries, 16 of red Currants, 9 o black, 7 of Raspberries, and 4 of strawberri-s.

The nurserymen's classes, such as Dobbie's Lane's, Todd's, the specimen Ferns and flowe the enormous masses of herbaceous plants, fi Begonias, were the most noticeable objects.

The specimen Conifers and Palms also did e furnish the spacious floors of the Waverley Mark

Pelargoniums, Fuchsias, stove and greenh Violas, Gladioli and Hollyhocks, were superbly

A pretty collection of Water-Lilies, as grown air, was shown by Mr. HUNSON of Gunnersbury, much interest. Some of the finer varieties we Marilacea carnea, aurora, sulphurea, tuberos Robinsiana, the last-named a very pretty crimson colour, and small, &c. Altogether, twenty-one varieties.

ROSES made a first rate display. Messrs. CRO HARKNESS, and others, showing as good blo have exhibited this season, the Messrs. CROLI ing the boards in the nurserymen's class, takin following classes:—Thirty-six, twenty-four, eigh and for twenty-four and twelve Pears. Also 1st fo

following:—Twelve Roses of one sort—a most brilliant display. Dozens of other sorts were also shown in perfect condition, making a fine collection in themselves, and securing 1st prizes in every class.

The choicest blooms among the different stands were perfect examples of the following:—Marie Van Houtte, Madame Hoste, Medes, The Bride, Innocente Pirola, Maréchal Niel, Souvenir de S. A. Prince, Captain Hayward, Prince Arthur, A. K. Williams, Susanne Rodocanachi, La France, and the dozens of single sorts were all good alike.

Mr. CROCKER, of Dundee, THOS. SMITH & SONS, Stranraer, and Messrs. HUGH DICKSON & SONS, of Belfast, were winners of several 2nds in various classes; Mr. CROCKER's 1st, however, for a dozen of Chas. Lefebvre, were magnificent blooms.

PRIZE LIST—FRUIT.

Collection of twelve dishes of fruit, 1st prize, J. HUNTER, Lambton Castle; 2nd, F. HARRIS, Elnor Castle, Ledbury; 3rd, J. W. McHARTIE, Strathfieldsaye.

Collection of eight dishes of fruit, 1st, F. HARRIS; 2nd, D. KIDD, Musselburgh; 3rd, RICHARD CAIRNS, Balrudeary, Dundee.

Collection of twelve dishes of hardy fruit, 1st, J. DAY; 2nd, J. NICHOLSON, Essex; 3rd, T. H. COOK.

Collection of twelve dishes of fruit grown in an orchard-house, 1st, J. HUNTER; 2nd, JAS. GIBSON, Chiswick; 3rd, W. WILLIAMSON, Tarvit.

Six bunches of Grapes, in three varieties, 1st, T. LUNT; 2nd, R. CAIRNS; 3rd, J. LESLIE.

Four bunches of Grapes, distinct varieties, 1st, D. KIDD; 2nd, Messrs. BUCHANAN, Forth Vineyards; 3rd, D. AIRDRIE.

Two bunches of Muscat of Alexandria, 1st, D. KIDD; 2nd, R. CAIRNS; 3rd, W. RUTHERFORD.

Two bunches of Black Hamburg, 1st, J. MATHIAS; 2nd, J. MENZIES; 3rd, T. SUTHERLAND.

One bunch of Muscat of Alexandria, 1st, P. MACDONALD; 2nd, D. KIDD.

One bunch of Black Hamburg, 1st, J. MENZIES; 2nd, PATTERSON.

One bunch of Alicante, 1st, P. HUNT; 2nd, Messrs. MURRAY & SONS.

One bunch of Alnwick Seedling, 1st, A. HUTTON; 2nd, T. LUNT.

One bunch of Gros Colmar, 1st, D. MACPHERSON; 2nd, W. MURRAY & SONS.

One bunch of Lady Downes, 1st, D. AIRDRIE; 2nd, J. DAY.

One Queen Pine-apple, 1st, D. KIDD; 2nd, D. MURRAY.

One Pine, other variety, 1st, M. MALOJUM McINTYRE, Glen.

One Melon, green-headed, 1st, A. RICHARDSON, Craig Park; 2nd, J. WALSH, Dollar.

One Melon, scarlet-headed, 1st, A. RICHARDSON; 2nd, J. RAMAGE.

Twelve Figs, 1st, J. MORRISON; 2nd, M. McINTYRE.

Twelve Peaches, 1st, F. HARRIS; 2nd, JAS. COSAR.

Twelve Nectarines, 1st, T. LUNT; 2nd, J. MORRISON.

Twelve Apricots, 1st, D. MACKAY; 2nd, Wm. LAING.

Twelve Plums, Gages, 1st, W. LAING; 2nd, F. HARRIS.

Twelve Yellow Plums, not Gages, 1st, J. HARPER, Jersey; 2nd, F. HARRIS; 3rd, THOS. BOWMAN.

Twelve Red or Purple Plums, 1st, J. HARPER; 2nd, F. HARRIS.

Collection of Dessert Plums, four varieties, 1st, J. DAY; 2nd, THOS. BOWMAN.

Collection of Culinary Plums, four varieties, 1st, J. HARPER; 2nd, J. DAY.

Collection of Apples, two varieties, ripe or unripe, 1st, JAS. GIBSON; 2nd, J. F. McLEOD.

Collection of Apples, grown in Scotland, twelve varieties, 1st, J. DAY; 2nd, D. MURRAY.

Collection of Apples, six varieties, 1st, J. CAIRNS; 2nd, Wm. LAING.

Six dessert Apples, no two varieties, 1st, JAS. GIBSON; 2nd, J. HARPER.

Collection of Pears, twelve varieties, four of each, ripe or unripe, 1st, J. HARPER; 2nd, JAMES GIBSON.

Collection of Pears grown in Scotland, six varieties, four of each, 1st, D. MURRAY; 2nd, T. H. COOK, Gosford.

THE VICTORIAN ERA CLASSES

Were so named in commemoration of the Diamond Jubilee of Her Majesty the Queen, and because the Council of this society desired to bring prominently before the public the remarkable advance made in the leading branches of horticulture during the Queen's reign, as exemplified in the best produce of British horticulture at the present time. The Council therefore hopefully anticipated that this competition would be a noteworthy one, and that the exhibits displayed would form a record in the history of British gardening. In the 1st class the prizes amounted to thirty-nine guineas, with a 1st prize of twenty guineas, a 2nd of twelve, and a 3rd of seven guineas. The class was for a table of fruit 20 feet long by 4 feet 6 inches wide, tastefully decorated for dessert.

The Veitch Memorial Silver Medal was awarded with the 1st prize, the Society's Diamond Victoria Silver Medal with the 2nd, and the Society's Jubilee Bronze Medal with the 3rd. Five competitors entered the lists, and it is only needful to name the exhibitors to note the nature of the struggle between them: Mr. J. HUNTER, Lambton Castle Gardens, who took 1st prize; RICHARD CAIRNS, Balrudeary House Gardens, Dundee, who was 2nd; ALEXANDER KIRK, Norwood, Alloa, 3rd.

Prizes of equal value (thirty-nine guineas) in money, accompanied with similar medals, were awarded to the best group of plants tastefully arranged on a space not exceeding 300 square feet of the floor of the Hall.

There were only three competitors:—JOHN McINTYRE, Woodside Gardens, Darlington, who took 1st prize; Mr. McINTYRE, the Glen Gardens, Innerleithen, 2nd; Mr. JOHN DOWNIE, Edinburgh, 3rd.

For cut flowers in class 3 the prizes were a 1st of ten guineas, a 2nd of seven guineas, and a 3rd of four, with accompanying medals for the best and most artistically-arranged table, 15 feet long by 5 feet wide, of cut flowers, hardy plants, and half-hardy annuals grown in the open air. Each bunch was formed of one variety, set up in vases or other suitable receptacles with their own foliage, no other to be used, and no plants in pots to be set upon the table. There were five entries in this class, the tables made a fine display; but it surely must have been an accident that Roses were excluded from the cut-flower tables with Dahlias, Chrysanthemums, Pelargoniums, and other tender plants and flowers. Messrs. HARKNESS & SONS, Bedale, were 1st; Mr. JAMES COCKER, Aberdeen, 2nd; and Mr. JAS. FORBES, 3rd.

Class 4, called for a table of vegetables 12 feet by 5 feet wide, tastefully arranged, consisting of twenty-five dishes, and not fewer than sixteen kinds, and not more than two dishes of two distinct varieties of any one kind. The same money prizes and medals were awarded as for cut flowers, viz., ten guineas, seven guineas, four guineas, with medals and cash. It is almost a new departure in showing vegetables to ask and provide space for their neat, tasteful, and effective arrangement, but no decorations—plants, flowers, or foliage—were used, but pot or sweet herbs, the foliage or sprays of culinary vegetables, green moss or a suitable cloth.—Open to Gardeners and Amateurs (four entries). JAMES GIBSON, Drumhwa, 1st; ROBERT R. RAE, Drumlan, Roxburg, 2nd; WILLIAM HARPER, Tullibet House Gardens, Perth, 3rd.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

* 2	1	118	0	+ 348	− 80	6	155	24.0	46

The districts indicated by number in the first column are the following:—

- 1, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S.
- Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W. 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending September 4, is furnished from the Meteorological Office:—

"The weather was again in a very unsettled, rainy condition, but with some fine intervals, the latter being most marked in the southern and south-eastern districts. Thunder

and lightning occurred in many parts of England during the latter part of the period.

"The temperature was below the mean in all districts, the deficit ranging from 1° in 'Scotland, N.' and 'England, N.E.' to 5° in most of the western districts and in the 'Midland Counties.' The highest of the maxima were registered on August 30, and ranged from 73° in 'England, E.' to 65° in Ireland, and 68° in 'Scotland, W.' The lowest of the minima, which were recorded on September 4, ranged from 31° in 'Scotland, E.' (at Braemar), and 34° in 'Scotland, N.' to 41° in 'England, N.W.' and to 49° in the 'Channel Islands.'

"The rainfall was greatly in excess of the mean; in 'England, N.E.' the fall was as much as four times the normal, and in nearly all other parts of the kingdom two or three times.

"The bright sunshine was less than the mean in most districts, but slightly exceeded it in 'England, S. and E.' and over Ireland. The percentage of the possible duration ranged from 47 in 'England, E.' and 46 in 'England, S.' and the 'Channel Islands,' to between 26 and 30 in Scotland."

CONTINENTAL NOVELTIES.

A VARIEGATED-LEAVED SUNFLOWER.

SOME leaves, young, and also of full size, of a variegated dwarf form of *Helianthus annuus* reach us from Mr. F. Roemer, seed grower of Quedlinburg, which have a rather striking effect. The variegation consists of irregular patches of creamy-white on a green ground colour. The plant, if it come true from seed, might be of use in shrubberies and rough places in the garden.

NEW INVENTION.

A PLANT PROTECTOR.

WE have recently received a model of a very simple plant protector. An ordinary flower-pot is used, the interior is whitened, and the bottom sawn off in such a manner that two grooves remain. The pot being inverted, a piece of glass is fitted into the grooves, and is thus secured against disturbance from wind. It is proposed to use these protectors to place over delicate plants in spring, that may by such means be safely planted out in the open much earlier than the work is usually done, and the plants becoming established in their permanent positions, a longer season of bloom will ensue. It is urged that being made in different sizes, these protectors will be useful for placing over all sorts of delicate bedding plants, Potatoes, and many other things. It is probably intended for amateurs rather than professionals, though the latter may find such a cheap contrivance useful. A patent has been applied for by a Mr. H. Thompson.

MARKETS.

COVENT GARDEN, SEPTEMBER 9.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly very Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

FRUIT.—AVERAGE WHOLESALE PRICES.

	s. d. s. d.		s. d. s. d.
Apples, Dessert, in variety, p. bush.	8 0-10 0	Nectarines, selected fruit, per doz.	6 0-8 0

		— Channel Islands, per lb.	0 2-0 3

POTATOS.

Supplies are still rather light, and some descriptions have advanced a shade since last report. Ruling prices as follows:—Hebrons and Snowdrops, 70s. to 90s.; Giants, 70s. to 80s.; Blacklands, 60s. to 65s.—John Bath, 32 and 34, Wellington Street, Covent Garden, W.C.

SEEDS.

LONDON: Sept. 8.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that there were but few buyers on to-day's seed market. With respect to Trifolium, both supply and demand are now alike falling off. For Mustard and Rape seed there is a small inquiry on former terms. Choice new Winter Taroas are offering at tempting rates. Giant seed Rye is scarce and firm. Full prices are asked for Alayke and Trefoll. Hemp and Canary seed, without much business passing therein, are both very firmly held. Wisconsin Peas and Haricot Beans are 2s. higher. Californian Butter Beans meet with increasing favour at advancing quotations. Linseed is quiet.

FRUIT AND VEGETABLES.

GLASGOW: Sept. 8.—The following are the averages of the prices current here during the past week:—Pears, 3d. to 8d. per lb.; Apples, 4d. to 6d. do.; Plums, 4d. do.; Tomatoes, Guernsey, 3d. to 4d. do.; do., Scotch, 5d. to 7d. do.; Grapes, home, 1s. 6d. to 2s. do.; do., foreign, 6d. to 1s. do. Vegetables:—Golden Ball Turnips, 1s. 6d. to 2s. per doz. bunches; Cabbages, Scotch, 6d. to 8d. per dozen; Cauliflowers, Scotch, 1s. 3d. to 1s. 6d. per bunch; do., Dublin, 2s. 6d. do.; Parsnips, 5s. to 6s. per cwt.; herbs, assorted, 1d. to 2d. per bunch; Mint, green, 6d. do.; Onions, Dutch, 3s. 6d. to 4s. per bag; do., Portugal, 1s. per stone; Parsley, 9d. to 1s. do.; Potatoes, 8d. to 10d. do.; Carrots, 10d. to 1s. per dozen bunches; Peas, 5s. to 10s. per cwt.; Cucumbers, 4s. to 4s. 6d. per dozen; Lettuces, round, 6d. to 9d. do.; do., Cos, 6d. to 9d. do.; Radishes, 4d. to 6d. per dozen bunches; do., London, 1s. 6d. do.; Horseradish, 2s. 3d. to 2s. 6d. per bundle; Beans, Broad, 1s. per stone; do., French, 3s. 6d. to 4s. per sieve; Mushrooms, 1s. per lb.; Beetroot, 4d. to 5d. per bunch; Mustard-and-Cress, 3d. per punnet; Spinach, 2s. to 2s. 6d. per stone; Rhubarb, 1s. 6d. to 2s. per cwt.

LIVERPOOL: Sept. 8.—Average of the prices at under-noted markets:—St. John's Potatoes, 1s. to 1s. 4d. per peck; Cucumbers, 3d. to 6d. each; Nectarines, 3d. to 4d. each; Peaches, 6d. each; Grapes, English, 1s. to 2s. 6d. per lb.; do. foreign, 4d. to 6d. do.; Pines, English, 5s. to 7s. each; do. foreign, 1s. do.; Mushrooms, 4d. to 6d. per lb. Birkenhead:

Potatoes, 10d. to 1s. peck; Cucumbers, 2d. to 6d. each; Grapes, English, 1s. 6d. to 3s. per lb.; do., foreign, 6d. to 8d. do.; Pines, English, 4s. 6d. to 7s. each; Peaches, 4d. each; Mushrooms, 4d. to 8d. per lb.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending September 4, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1896.	1897.	Difference.
Wheat	23 1	33 7	+ 10 6
Barley	21 11	25 11	+ 4 0
Oats	19 11	17 6	+ 3 1

BOG AND AQUATIC PLANTS: *Enquirer*. Aponogeton distachyon, Butomus umbellatus, Calla palustris, Hottonia palustris, Lythrum roseum superbum and L. salicaria, Menyanthes trifoliata, M. nymphoides, Nuphar advena, N. lutea, Maris' Nymphaea, and others; Pontederia cordata, Villarsia nymphoides, Iris pseudo-acoris, and I. palustris.

BOOKS: X. Y. Z. *The Rose Garden*, by Mr. W. Paul (Kent & Co., 23, Paternoster Row); *Folklore of Plants*, by T. F. Thiselton Dyer (Chatto & Windus); and *The Book of the Rose*, by Rev. A. Foster-Melliar (Macmillan & Co.)

BUSHES AND TREES FOR MARGINS OF WATER: *Enquirer*. Hardy Rhododendrons, Pernettyas, Gaultheria Shallon, Cotoneasters various, Aralia spinosa, A. Sieboldi, Yucca gloriosa, Y. filamentosa, Y. flaccida, the more ornamental Alders, as A. glutinosa laciniata, A. cordata, &c., American Oaks, American red Cedar (Juniperus virginiana), Pinus strobus, Willows, Poplars, especially Populus canadensis, P. Abels, and P. tremula; Catalpa speciosa, and C. syriensis. For all of these plants special stations should be made by digging out the staple, and filling up with suitable mixture. Ferns, Rhododendrons, and American plants generally, like a soil in which peat or a fibry loam forms the chief part, together with a good proportion of sand. If the staple be of fair quality, a small quantity of new loam will make it good enough for most kinds of trees, but it should be trenched 3 spits, and lay exposed for an entire winter. All ground before it is fit to carry plants not naturally inhabitants of a marshy soil should be drained in some manner, and rubble drains are the best for such land, these being placed low enough to obtain a fall to the outlet, and yet drain the land 3 to 4 feet deep.

CORRECTION.—Mr. Henry Merryweather desires us to rectify "Wild Rose's" statement regarding the premier bloom of Niphetos Rose staged at the National Rose Society's show at Norwich, of which he was the exhibitor. See *Gardeners' Chronicle* for last week, p. 158.

COUCH-GRASS AND LILY BULB: W. T. The perforation of bulbs and tubers by the roots of Couch-grass is of common occurrence.

GRAPES CRACKING: *Perplexed*. The effect of much moisture having access to the border after a long period of drought, aggravated probably by undue denudation of foliage, and an over-moist atmosphere in the vinery, with insufficient ventilation.

NAMES OF FRUITS: G. C. A Codlin, evidently, perhaps Keswick; but fruit arrived in too poor a condition to determine.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number*.—J. A. Dendrobium chrysanthum.—R. W. P. 1, Amaryllis belladonna; 2, Eryngium amethystinum; 3, Heuchera glabra; 4, Pteris argyrea.—C. M. Rogers. Spiraea sorbifolia, the flowers are white, paniculate.—J. Smith. 1, Spiraea callosa; 2, Spiraea satifolia; 3, Spiraea Douglasii; 4, Diervilla floribunda.—G. F. Statice Gmelini.—John Clayton. Asclepias fruticosa.—G. H. S. 1, No specimen; 2, a garden variety of

Rose; 3, Atropa belladonna; 4, Pernet nata; 5, Silphium laciniatum; 6, S. aquatica; 7, Clethra alnifolia.

PLANTS FOR MARGINS OF WATER: *Enquirer* almost any species, New Zealand flax Donax, and the variegated form of it, scabra, Rhubarb, Hartstongue Fern, regalis, Polypodium vulgare in its varieties, Polystichum aculeatum, P. many forms; Woodwardia orientalis, L. tata, L. spinulosa, L. dilatata in shady montana in cool and damp ones. Ma Alpine plants so-called, if planted in w rockeries or parts of the bank that a efficiently, do and look well by the side &c.; if planted in big patches, viz., Campanula caespitosa, C. pulla, C. carpat binata, Dianthus alpinus, Gentiana: verna, Iberis corneifolia, Myosotis i Phlox Nelsoni, P. frondosa, P. subulata oeymoides.

PALM: J. Carter. I find no fungoid d's little white mould is superficial and as It seems impossible for a plant to liv roots compressed into a pot in this mai out soil or sustenance—that is quite account for anything. M. C. C.

PEAR TREE: J. M. When the leaves to any necessary pruning may be done wi that any injury will occur to the tre all redundant growth down to the old afterwards keep it under by early rem summer; and persistently keep the cen head clear of shoots. The best fruits (the spurs (not too long), and the termina old shoots. Do not carry out much w ing after your tree is brought into pr but rely upon two summer prunings, June, and late in July. Marie Louise long spurs, and a close inspection shoul when shortening these, that those termi fruit-bud are not cut off unless unduly l

ROSE-BUDDING OF DWARF STOCKS: F. T. the stem just below the ground-level is one.

"SETTING" THE FLOWERS OF CUCUMBER: The pollen should be employed for f about noon, and it should be taken fr that have been expanded about two hours it that you mean by word "ripe," that t had been open much longer than that useless for fertilising purposes, the pol fallen on the soil, or been eaten by bees,

SITUATION ABROAD: T. H. With your ac and foreign experience you should have n in filling an appointment. Advertise in *Tropical Agriculturist*, and this journal.

STRONG BRIAR-SHOOTS IN HEDGES: F. T. be budded without removal, taking then spring; but this job must be carefully d bud may die. Such Briars may also l trimmed at the roots, and potted in 32s in January grafted with Rose-shoots in ture of 58° to 69°. These will flower ur house treatment in April.

TOMATOES: J. W., Hampstead. The fruits ar by the "Black-spot" fungus, Clados copercioi, so often described and figur columns. Remove and burn at once t that is so affected.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the honor of announcing that the circulation of the *Chronicle* has, since the reduction in the price

MORE THAN DOUBLED, and that it continues to increase

Advertisers are reminded that the "*Chronicle*" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDEN-LOVERS at home, that it has a FOREIGN AND COLONIAL CIRCULATION, and is preserved for reference in all the principal Libr

THE

Gardeners' Chronicle.

SATURDAY, SEPTEMBER 18, 1897.

CAEN.

NOW that the London, Brighton & South Coast Railway Co. have established a line of small, but comfortable, steamers direct from Newhaven to Caen, horticulturists, botanists, and anybody else who has the opportunity, might easily do worse than take a trip to Normandy by this route. The boats are necessarily small because they have to go up a canal, some 9 miles long, from Onistreham (the name of which is strikingly suggestive of our Kentish town of Westerham) to Caen, but the sea-voyage of nearly 150 miles only occupies seven hours, and the fares are moderate itself.

This is not the place to dwell on the manifold interest of the ancient town of Caen to the student of history or of architecture. In these respects, the most competent of authorities, the late Professor Freeman, has compared it to Oxford. William the Conqueror and his queen lie buried here, each in a magnificent abbey-church of their own foundation—or rather Matilda still lies undisturbed, whilst the bones of the Conqueror have been scattered no man knows where; whilst, besides these two noble specimens of Norman architecture, there is at least one other church in the town, that of St. Pierre, worthy to rank with many of our English cathedrals. The castle, also founded by the Conqueror, and once garrisoned by 4000 English soldiers, still frowns over the town, with its deep though dry moat, its draw-bridges, and its machicolated gateway; crumbling, half-timbered houses in many of the streets recall Chester or old London, and at every turn dark entries, with round-headed stone arches or picturesque gables, offer attractions to artist or photographer. In the Hôtel de Ville is a by no means despicable library and picture gallery; but it is as the seat of a well-equipped University with three faculties (letters, medicine, and science), and of a small, but excellent, botanical garden, that Caen is most likely to interest readers of the *Gardeners' Chronicle*. The University possesses a natural history museum, containing the valuable ethnological collections of Dumont d'Urville, the great navigator, who was born in 1790 at the small manufacturing town of Condé sur Noireau, some thirty miles south of Caen. In France they appreciate the honour due to men of science: and in Caen, besides a Place Malherbe, named after the poet who was born there; and a statue of Auber the composer, also a native of the town; a street and statue commemorate Laplace the astronomer, and Elie de Beaumont the geologist, two illustrious natives of the department of Calvados, in which Caen is situated; a Rue Desmoneux and a Place Blot do honour to the founder and chief benefactor of the Botanical

Garden; and a Rue Pasteur bears a name which belongs to the whole world of science.

The Jardin des Plantes is on the outskirts of the town, approached by the Rue Desmoneux, and facing the Place Blot, and occupies rather high ground, sloping mainly towards the north-east. It is of irregular outline, about a quarter of a mile long, but less than half as wide, a considerable portion of its upper part being little more than a shrubbery, the trees in which are not labelled. The original garden, the foundation of Desmoneux, at the north end, is now devoted to propagating purposes, all the public portion of the present garden occupying the site of a quarry of the celebrated Caen stone, which was presented to the municipality by Dr. Frederic Blot, a physician of the town. On the grass slopes of the quondam quarry, there is now some effective bedding, in which Cannas, Begonias, and *Lobelia cardinalis* play the chief part. The good trusses of bloom on the *Pelargoniums* used for bedding-out, here, and in most of the cottage windows in the neighbourhood, are very noticeable.

In the centre of the garden is a fine block of houses, comprising a central hall and staircase, over which is the museum, herbarium, and small lecture-theatre; a small but lofty gable-topped temperate-house, and a more recently-added iron-framed, curved-roofed Palm-house, entirely covered with excellent, narrow-slatted Venetian blinds. Both houses at the time of my visit were at 25° C. (77° F.), but, except for its walls, which were nearly covered with *Heliotrope*, and a large specimen of *Yucca guatemalensis*, about 20 feet high, with a stem over a foot in diameter, the temperate-house was all but empty; a number of fine tall plants of *Mimosas*, *Eucalypti*, *Proteas*, *Benthamia*, *Araucaria*, *Chamærops*, &c., in tubs, being out-of-doors for the summer. In the Palm-house is a large Date-palm and a fine plant of *Pachira insignis* from Martinique, and, throughout the collection, as is only natural, and as is to a great extent the case with our own national collections, the colonies of the country were better represented than other foreign lands. I also noticed a good specimen of *Xylophylla arbuscula*, and one of *Euphorbia Hermentii* from the Gaboon. The plants in the houses are almost all labelled, the larger specimens bearing also the names of their donors. Below the level of the gravel terrace in front of the principal block is a range of seven good-sized "petites serres," partly underground, well-stocked with clean, well-grown plants; but without any arrangement and, considering the reputation of M. Angis—the late director and father of the present director—as an orchidist, very few Orchids. It should be mentioned, however, as an excuse for any shortcomings, that the gardens are under a not too lavish municipal control, and that M. Angis, with some fifteen men under him, is responsible for all the little gardens in the squares of the town. In the grounds a large Myrtle, *Cephalotaxus Fortunei* in full fruit; and several *Catalpas* covered with blossom, told of a mild climate. In the lowest and most sheltered part of the garden is the botanical garden proper, in which, in a space not larger than the student's garden at Kew, is a much more extensive series of hardy plants systematically arranged according to their Natural Orders. Here there were strikingly few gaps, and still fewer of those errors which so commonly arise from strong-growing self-sown usurpers. The white enamelled-iron labels with black lettering were only too

conspicuous, all of them being about 3 feet high; but the use of separate generic labels, the generic name not being repeated on the others, did not seem to facilitate study. One agreeable feature of this collection, on the other hand, is, that not only shrubs but trees, such as *Catalpa*, *Paulownia*, *Liriodendron*, *Magnolia acuminata*, and *M. macrophylla*, were in their proper places in the systematic sequence. Two small ponds afforded an insufficient representation of aquatic plants.

In the centre of the botanical garden is a commodious botanical institute, which, together with a marine laboratory at Luc-sur-Mer, a watering-place 14 miles from Caen, is under the control of the Faculty of Sciences of the University. The building is about the same size as the Jodrell Laboratory at Kew, and by the kindness of Dr. Léger, one of the botanical staff, who happened to be in residence, though the vacations had commenced, I was enabled to inspect all the arrangements. Besides small private studies for the professors, a small but sufficient reference library, in which Dr. Léger pointed out Bentham and Hooker's *Genera Plantarum* and the *Index Kewensis* as being in daily use; and a carpentry room, in which was a lathe for grinding sections of fossil plants; there was a roomy well-lighted dissecting-room, with lockers for each student containing a Hartnack microscope, with camera lucida, dissecting microscope, and re-agents. Students of two classes work here; from twenty to thirty at a time belonging to the Faculty of Medicine, and about half as many preparing for graduation in science.

The museum, over the central hall of the glasshouses, is small. It contained some sections of timber-trees grown in the gardens, some interesting colonial timbers, and a systematic collection of fruits and seeds; but its chief interest is the herbarium, which is chiefly that of Lenormand, but also includes a very valuable collection from New Caledonia, made, during a residence of fifteen years, by M. Vieillard, a navy surgeon. The Lenormand herbarium is very extensive, filling several rooms, and comprises cryptogams as well as flowering-plants. The latter are arranged according to De Candolle's *Prodromus*; but a very ingenious index to it has been prepared, based upon Durand's index to Bentham and Hooker. This consists of a small chest of drawers filled with cards, ordinal ones standing higher than the others, generic ones written on yellow card, and the species in each genus in alphabetical order.

CAEN FLOWER SHOW.

On the occasion of the annual race-meeting at the beginning of August, whilst the boating club organised a most picturesque and successful Venetian fête on the Orne, the Horticultural Society of Caen and Calvados held a three days' flower show in the Hôtel de Ville. On one evening of the show an excellent instrumental concert was given by a large military band. The number of competitors was not great, nor did the exhibition seem to have been sufficiently advertised, but the exhibits of the prize-winners were of so high a degree of excellence as to demonstrate that the florists of Caen fully understand their business. Amateurs were not well represented, nor, with the exception of some samples of the remarkable Louis Gauthier Strawberry, preserved in spirit, were fruit or vegetables at all prominent. Of this Strawberry I can only say, from what I saw, that its fruits reach a circumference of 9½ inches. Five of them are stated to have weighed 1½ lb..

and the variety has the additional valuable quality of bearing a second crop in August and September on the runners. It was produced by the gardener whose name it bears at the Château of Gronthéville, distant about 5 miles from Caen. The chief floral exhibits that attracted my attention were a group of Coleus (awarded a Gold Medal), exhibited by M. Marcel Lepage, 23, Rue des Marais, Caen; a group of very fine tuberous Begonias, effectively edged with *Linaria multi-punctata erecta* (Silver-gilt Medal), exhibited by M. Rouette of 88, Rue de Vancelles, Caen, who also obtained a Silver-gilt Medal for *Petunias*, and Bronze Medals for *Zinnias* and *Verbena*; a group of *Pelargoniums*, awarded a Gold Medal, was exhibited by M. A. Lenormand, 11, Rue St. Mauveur, Caen; another excellent group, awarded a Silver Medal, was exhibited by M. L. Davy, 200, Rue Caponière, Caen, who also obtained a Silver Medal for Coleus; and last, but not least, the collection of varieties of *Thalictrum glandulosum* exhibited by M. Léon Haretto, of 3, Rue Gémare, Caen. Two of these, novelties of 1896, "Nuits d'Orange," and "Nuit de Carnot," the one a lurid brown-yellow, the other a very deep crimson, are exceptionally fine. Certainly, the gardens of such cultivators as these gentlemen, would alone make the capital of Calvados well worth a visit. (H. H. Soudyger.)

BOOK NOTICE.

THE HAMBURG BOTANICAL GARDEN.

In connection with the remarkable Horticultural Exhibition now in progress at Hamburg, it may be of interest to allude to the Botanic Garden, long under the direction of our correspondent, Dr. Reichenbach. Dr. Voigt has, by authority of the educational officials of Hamburg, prepared a complete history of the botanical institute of that city, illustrated with reproductions of photographs of the principal points of view in the garden, the museum (interior and exterior), and some of its contents, besides plans and maps of the garden and museum in their past and present aspects.* Dr. Voigt has divided his book into two portions and an appendix. In the first section he traces the origin of the garden, and includes a biographical memoir of Dr. Johannes Flüge, to whose travels a collection of botanical specimens was due its foundation. Dr. Flüge died in 1816, his last days being embittered by the grief of seeing the garden upon which he had bestowed the work and zeal of a lifetime destroyed by the bombardment of the city by the French. The garden was not re-instated for nearly five years after this event, when Dr. Lehmann was appointed director. After his death, there was again an interregnum of some three years before Dr. Reichenbach was offered the vacant post. Under his régime, the area of the garden became greatly extended, the plant collections were re-arranged according to a more modern system of classification, and vast numbers of new specimens were purchased. The description of the present condition of the botanic garden occupies the third chapter of Dr. Voigt's book, and the second section is devoted to a notice of the earliest collections of botanical specimens that were made in Hamburg, and to that of the development of the museum, the original model being the similar institution at Kew. Although the question of founding such a museum had often been brought forward, no decided steps were taken in the matter till 1879, when Dr. Buck bequeathed his carpological collections to the State on condition that their custody should be entrusted to competent men in order that they might become of permanent value and be constantly added to and enlarged. They included seeds and fruits of

about 10,000 plants, brought together from all parts of the world. Dr. Binder's collection of Algae was acquired by the exertions of Dr. Sonder in the same year, and so rapidly did the specimens accumulate that they were amalgamated under the title of the Botanisches Museum in 1883. In 1894 the collections were removed to their present imposing and commodious quarters. Here are the herbaria, the collections of woods and seeds; the library, the work-rooms and laboratories, all of which are fully described in Dr. Voigt's book. The appendix is devoted to a list of the names of the officials connected with the Botanical Institute from the time of its foundation, the numbers of the species of every genus of plants grown in the garden at the present time, and many other details connected with the library, museum and laboratory.

WALNUTS, CHESTNUTS, AND ALMONDS.

In order to answer the many inquiries relating to the composition of Californian Nuts, and to the manures required to replace the exhaustion of the soil caused by their growth, Mr. G. E. Colby began the work of investigating samples of Walnuts, Chestnuts, and Almonds grown in various parts of California, each variety of Nut and its parts being considered separately. The physical analysis, the ash, nitrogen contents, and the kinds of fertilisers necessary to replace the soil ingredients taken away by the Nut crops are first considered; then the question of the composition of the kernels of the Nuts with reference to their food-values, is briefly dealt with.

WALNUTS.

Six varieties of Walnuts were examined of the growth of 1895; they were gathered from trees upwards of eight years old, grown in districts which well represent Walnut-producing localities. The Bijou Walnut is more of a curiosity than anything else, still it deserves the place given it.

The following table gives the results of the physical analysis, and the ash and nitrogen contents of the various parts of the Walnut:—

COMPOSITION OF CALIFORNIAN WALNUTS.

Constituents.	Variety—Soft-shell.			Bijou.	Native Black
	Orange County.	Los Angeles County.	Amador County.		
<i>Physical Analysis.</i>					
Entire fresh fruit:—					
Average weight of nuts grams*	13.30	15.80	13.30	31.00	14.10
Average weight of hulls	20.00	17.50	11.70	49.00	35.90
Total weight ..	33.30	33.30	25.00	80.00	50.00
Nuts, proper per cent.	40.00	47.50	45.00	37.50	30.00
Hulls	60.00	52.50	55.00	62.50	70.00
Fresh Nuts (hulled):—					
Average weight of kernels ..	6.00	6.65	5.10	8.34	3.75
Average weight of shells	7.30	9.15	8.20	22.66	10.35
Total weight ..	13.30	15.80	13.30	31.00	14.10
Kernels ... per cent.	45.00	42.10	38.30	26.90	25.90
Shells	55.00	57.90	61.70	73.10	74.10
<i>Ash and nitrogen.</i>					
Fresh nuts (hulled):—					
Ash per cent.	0.78	0.64	0.83	0.68	0.57
Nitrogen	1.00	1.00	1.08	0.81	0.98
Fresh kernels:—					
Ash... ..	1.16	1.05	1.18	1.36	1.26
Nitrogen	1.82	2.09	2.45	2.40	3.16
Fresh shells:—					
Ash... ..	0.61	0.35	0.62	0.41	0.30
Nitrogen	0.32	0.21	0.23	0.20	0.20
Fresh hulls:—					
Ash... ..	1.15	1.83	2.21	1.06	0.51
Nitrogen	0.11	0.28	0.17	0.15	0.12

* About 30 grams, an equivalent to 1 ounce.

The Bijou Walnut is very large, weighing 24 as an average, or more than twice the weight of ordinary Walnuts. While the hull is also quite different in percentage of the entire fruit, 62.5, is not much greater than that of the soft-shell, and less than that of the native black. The same is with regard to the proportion of shell in the nut, 73.1 per cent.

Between the three soft-shell varieties there are differences other than would naturally occur samples from different trees or localities.

average weights are, of nuts, 14.1 grams; hulls, grams; shells, 8.2 grams; and of kernels, 5.9 grams.

It is remarkable that the percentage of nitrogen the fresh nuts (hulled), and in the fresh kernel is much greater than is the percentage of ash. In the case of the native black variety the nitrogen the fresh kernels is nearly three times more than the amount of ash, and twice as much in the soft-shell varieties from Los Angeles and Amador counties.

CHESTNUTS.

Two samples of Californian Chestnuts were examined, both of the Italian variety, one grown Santa Paula, Ventura county, and the other Clinton, Amador county.

The following table gives the results of physical analysis, and shows also the ash and nitrogen contents, in the various parts of the Chestnut fruits.

COMPOSITION OF CALIFORNIAN CHESTNUTS.

Constituents.	Grown in Santa Paula.	Grown in Clinton.
<i>Physical Analysis.</i>		
Entire fresh Fruit:—		
Average weight of Nuts grams	28.50	21.1
Average weight of hulls	21.50	11.1
Total weight	50.00	32.2
Nuts per cent.	57.00	65.5
Hulls	43.00	35.5
Fresh Nuts (hulled):—		
Average weight of kernels, grams	24.08	18.1
Average weight of shells	4.42	3.1
Total weight	18.57	21.2
Kernels per cent.	84.50	84.5
Shells	15.50	15.5
<i>Ash and Nitrogen.</i>		
Fresh Nuts (hulled):—		
Ash per cent.	0.83	0.6
Nitrogen	1.02	0.6
Fresh Kernels:—		
Ash	0.75	0.6
Nitrogen	1.06	0.6
Fresh Shells:—		
Ash	0.99	0.6
Nitrogen	0.76	0.6
Fresh Hulls:—		
Ash	1.21	0.6
Nitrogen	0.50	0.6

Of the two samples of Chestnuts examined from Santa Paula is clearly the better, for it heavier nut and kernel, though the proportion of nut, with reference to the entire fruit, is greater than that from Clinton. The averages of the two taken as a possible average for Chestnuts in general are—hulls, 16.58 grams; nuts, 25.08 grams; 3.88 grams; and kernels, 21.21 grams.

ALMONDS.

Eleven samples of Almonds were examined, of light-weight, and four of heavy-weight. The from Davisville stands as the lightest of a varieties, viz., 5.2 grams, though its nut is somewhat heavier than that of King's soft-shell, 2.6 to 2.3 grams.

On the other hand, the Languedoc Almond heaviest of all, viz., 25 grams, though its nut is about like that of the light-weight varieties, 4.5 to 4.7 grams. The IXL Almond from Skyland, on the Santa mountain, has also a large hull, 4.4 grams; but it the largest nut of the lot, 7 grams, nearly times the weight of several of the others. The

* Die botanischen Institute der freien und Hansestadt Hamburg, von Dr. A. Voigt (Leopold Voss, Hamburg and 1897).

riety of the Foothill Station has a very heavy rasing 17 grams, and a nut as small as that ght-weight Ne Plus Ultra, viz., 3 grams; the on between the hulls and nut being greater h any other of the varieties. hus seen that, although an Almond fruit may and weighty as it comes from the tree, it by

Marie Dupreys, which ranks next to the Languedoc, the heaviest kernel of all.

NITROGEN CONTENT OF THE DIFFERENT FRUITS.

Referring again to the tables above, where the nitrogen is reported for nuts, kernels, shells, and hulls, it is seen that the average percentage for

closely with that mentioned for the Californian nuts. The difference in nitrogen in the kernels of the Pennsylvania and California Chestnuts is only a trifle.

The ash constituents, and the manurial requirements of the different trees, will be considered in a future article. *J. J. Willis, Harpenden.*

CODONOPSIS OVATA.

THE first mention of this pretty species is in Dr. Forbes Royle's *Illustrations of the Botany of the Himalayan Mountains*, p. 258, which was published in 1839. A figure of the plant is also given under t. 69, but it cannot be said to agree very well with the accompanying illustration (fig. 58), which was made from a plant shown at the Royal Horticultural Society's meeting, Westminster, on June 23, 1896, by Mr. Amos Perry, of Winchmore Hill. *Codonopsis* (*Glossocomia*) *clematidea*, as figured at t. 167 of the *Gartenflora*, seems to be much nearer the plant here figured so far as habit is concerned, but the flowers do not agree with those of that specimen either in size or colour. The plant shown at the Drill Hall was from 12 to 18 inches high, and bore several more or less drooping flowers of a pale blue colour outside, distinctly veined, and with a conspicuous purple zone about one-third the length from the base, at a point where some of the flowers are somewhat constricted. Looking into the flower, one may notice two zones of purple, then one of yellow, and one of black at the base surrounding the ovary. The plant is a native of the Himalayas, but, unless there is considerable variation in the species, there seems to be a doubt as to whether that here figured is really *Codonopsis ovata* or some other species not yet described. *John Weathers, R.H.S., London.*

NOTES ON THE CULTIVATED BRASSICAS.

IN common with nearly all cultivated plants, especially those which are perplexing, the Brassicas have recived too little attention from botanists. The inevitable outcome of such neglect or of any superficial study is a reduction of species, and in this direction Brassica has suffered greatly. It is usually confusing to reduce types. The most perplexing species in our manuals are those which contain the greatest number of old types or synonymous names. It is true that this is supposed to be primarily due to the variation of the species or groups, but I am convinced that it is often to be charged to superficial study or insufficient material. The conviction is growing upon me that our manuals contain too few rather than too many species; at all events, the miscellaneous dumping of *Rutabagas*, *Turnips*, *Rape* and other plants into *Brassica campestris* is unnatural, and therefore unfortunate. The best presentation of the species of true Brassicas which has yet been made is that of De Candolle's *Prodromus* so long ago as 1824, and my own studies lead me to adopt essentially those conclusions. I am not clear as to the generic merits of *Brassica* and *Sinapis*. If we are to erect generic characters upon general habit, the two might be kept apart, but I have not found structural characters with which to separate them, and for the purposes of this discussion I have kept them together. I should add, that I am acquainted with no group in which many of the difficulties of classification vanish more quickly upon a study of the growing plants than in these Brassicas. From my standpoint, the group may be divided as follows:—

a. Whole plant glaucous-blue when in flower; leaves of the flower-stems clasping; flowers various.

I. Leaves from the first more or less fleshy throughout, and glaucous-blue, even when young; flowers large and creamy-yellow, the petals conspicuously long-clawed, and the sepals usually erect.

1. *Brassica oleracea*, Linn., the Cabbage and Cauliflower tribe. Leaves smooth from the first, and the root never tuberous.
2. *B. Napus*, Linn., the Rape. Leaves smooth from the first, differing from *B. oleracea*

FIG. 58.—CODONOPSIS OVATA.
(Exterior of flowers pale blue, with purple zone.)

ns follows that the nut is also large, and, he cleaned product from a tree bearing such it is proportionately greater, it may not be ofitable than that from small-sized fruits. amining the results as to the proportion the kernel and the shell, it is found that the kernels are with the heavy-weight varieties, e exception of Drake's Seedling, which falls some of the light-weight Almonds; and the

hulled nuts stands thus:—Walnuts, 1.02 per cent.; Almonds, 1.64 per cent.; Chestnut, 0.80 per cent. of nitrogen. The largest part of this is contained in the kernel, as that in the shell of the Walnut is but one-sixth, that in the Almond-shell one-twelfth, and that of the Chestnut-shell one-tenth of the whole nitrogen of the hulled nut.

Comparing this with the European data we have, we find that the European nitrogen-content agrees

chiefly in habit, and more deeply scalloped leaves. The botanical position of the Rapese is open to doubt.

3. *B. campestris*, Linn., the Ruta-baga. First leaves hairy, the root usually tuberous.

II. Leaves, except upon the flower-stem, thin and green; flowers smaller and bright yellow, less prominently clawed.

- a. Plant potentially biennial (that is, the root hard and thickened, often distinctly tuberous); foliage firm in texture.

* Leaves distinctly hairy.

4. *B. Rapa*, Linn., the common Turnip. Leaves, prominently lyrate or interrupted below, the root tuberous.

** Leaves not hairy.

5. *B. chinensis*, Linn., the Pak-Choi Cabbage. Radical leaves wavy and ample, glossy green, obovate or round, obovate in general outline, either entire or obscurely wavy or even crenate, tapering to a distinct and thick strong petiole, which is generally not prominently margined; pod large and tapering into a beak half an inch long; root sometimes tuberous.

6. *B. napiformis*, Bailey (Bull. 67, Cornell, 1894), the tuberous-rooted Chinese Mustard. Radical leaves comparatively few, the blade thin and oval in outline, and on long and slender, slightly-feathered petioles, sharply and irregularly toothed, with a thin bloom; beak of the pod more abrupt; root distinctly hard and tuberous.

aa. Plant truly annual; foliage profuse, loose and soft.

7. *B. Pe-Tsai*, Bailey, l.c., the Pe-Tsai Cabbage. Numerous radical leaves, large and light green, oblong or ovate-oblong, crinkled and very veiny, and the margins wavy, contracted into a flat and ribbed petiole 1 to 3 inches wide, which is provided with a wide thin-notched or wavy wing; stem-leaves sessile, and clasping; pod of medium size, with a short cone-like beak; the leaves tend to form an oblong, loose head, like *Cos* Lettuce.

8. *B. japonica*, Sieb., the Californian Pepper-grass, Pot-herb Mustard. Rather numerous radical leaves, oblong or oblong-obovate, the margins either crisped or cut into many very fine divisions, the petiole distinct at its lower end; stem-leaves all petioled; pod very small, with a slender beak; the soft, thin leaves make excellent "greens."

- b. Plant green or but slightly glaucous when in flower; leaves on the flower-stems not prominently clasping; flowers small and yellow. (Essentially *Sinapis*.)

9. *B. juncea*, Cosson, the Chinese Mustard.

10. *B. nigra*, Koch, common Mustard of commerce.

11. *B. alba*, Boissier, white Mustard.

The most important innovations in this classification are the recognition of the peculiarities of the stem-leaves and the sizes and colours of the flowers; and it is to be noticed that the Ruta-baga and Turnip, which are ordinarily thrown together, fall into different categories. The differences between the Cabbage-like species and Turnip-like species in size and colour of flowers is really striking when the plants are flowered side by side. The Turnip-flower is more like that of Mustard than like that of the Cabbage tribes. The breaking up of the Oriental Cabbage tribe into the three species (*B. chinensis* proper, *B. napiformis*, and *B. Pe-Tsai*) is also an innovation, but I am unable to understand the plants in any other arrangement.

The point which I wish to urge particularly at this time is the specific distinctness of the Ruta-baga and Turnip, and I will contrast them more minutely. The tubers of the two are different in season, texture, and flavour. In the Ruta-baga the small leaves immediately following the seed-leaves are sparsely hairy, but all subsequent leaves are entirely smooth, densely glaucous-blue, thick, and Cabbage-like, with a fleshy petiole and midrib. In the Turnip the radical leaves are always more or less hairy, and they

are green and Radish-like, thin, with slender petiole and the leaves are much more lyrate, with interrupted leaflets on the petiole; the small leaves following the seed-leaves are also thinner and narrower, and more deeply scalloped. In the Ruta-baga the flowers are large, creamy, and Cabbage-like, while in the Turnip they are small, yellow, and Mustard-like, with shorter claws and more spreading calyx. The Turnips vary in hairiness, but the cone of expanding leaves, or the "heart-leaves," always shows the hairs distinctly, while the heart-leaves of the Ruta-bagas are entirely smooth, fleshy, and remind one of the young shoots of Seakale. I have grown most of the trade varieties of Ruta-bagas and Turnips, and they may be referred to their respective species as follows. Specimens are in the Cornell Herbarium.

Ruta-Bagas (*Brassica campestris*).—1, Bronze-top Swede; 2, Burpee's Breadstone; 3, Carter's Ruta-baga; 4, Carter's Imperial Hardy Swede; 5, Colson's West Norfolk; 6, Early White Vienna; 7, Improved American Purple-top Ruta-baga; 8, Improved Champion; 9, Improved Yellow Summer Turnip; 10, Improved Yellow Swedish; 11, Laing's Improved; 12, Lincolnshire Improved; 13, Long Island Improved Purple; 14, Long White French Turnip; 15, Shamrock; 16, Skirving's; 17, Sutton's Champion; 18, Taunton; 19, White Ruta-baga; 20, White Swede or Russian; 21, Yellow French.

Turnips (*Brassica Rapa*).—1, Aberdeen; 2, Black Stone; 3, Cow-horn; 4, Early Dutch Turnip; 5, Early Snowball; 6, Extra Early Milan Red-top Strap-leaf; 7, Extra Early Purple-top Munich; 8, German Teltow; 9, Green Barrel; 10, Green Globe; 11, Grey Stone; 12, Long White Tankard; 13, Montmagny; 14, New Golden Finland; 15, Pomeranian White Globe; 16, Purple-top Strap-leaf; 17, Purple-top White Globe; 18, Red-top Globe-shaped; 19, Red-top Strap-leaf; 20, Robson's Golden Ball; 21, Seven-top; 22, Teltow, or Small Berlin; 23, True Jersey Navet; 24, White Egg; 25, White Flat, or Globe; 26, White Model; 27, White Norfolk; 28, White Strap-leaf; 29, Yellow Aberdeen; 30, Yellow Globe; 31, Yellow Malta; 32, Yellow Stone.

Brassica oleracea must be held to include, I think, all the Cabbages, Kales or Borecoles, Collards, Brussels Sprouts, and Cauliflower and Broccoli; and most botanists appear to agree that the Kohl-rabi belongs here, but upon this point I am not fully satisfied. So far as I know, *B. oleracea* is the most variable species in cultivation in temperate climates, although Naudin would give this distinction to *Cucurbita Pepo*. But the *Brassica* varies immensely in nearly all its parts, while the important variations of the *Cucurbita* are confined to the fruit and length of bine. There are few plants in which contemporary evolution can be so well studied as in this *Brassica*.

The Chinese Cabbages, which are now coming into cultivation, possess unusual interest to both the horticulturist and botanist. They are not only exceedingly variable, but the variations are of such a character as to show very clearly what has been the genetic history of the garden forms. The species is now represented in cultivation by several widely different forms. Hemsley refers the Chinese Cabbages to *Brassica campestris*, but they really have little in common with that much-abused species.

The confusion into which our Brassicas have fallen is in some measure due to the different vernacular names which they bear in different countries. The French use the word *chou* generically to include all forms of *B. oleracea*, and the Ruta-baga, that is, all the blue thick-leaved Brassicas; while in England the Ruta-baga is called the Swedish Turnip. A tabular view of the different vernaculars may prove to be useful:—

French.	English.	American.
<i>Chou Cabus</i>	Cabbage	Cabbage
<i>Chou de Milan</i>	Savoy	Savoy Cabbage
<i>Chou à Grosse côtes</i>	Portugal Cabbage	Portugal Cabbage
<i>Chou de Bruxelles</i>	Brussels Sprouts	Brussels Sprouts
<i>Choux-verts</i>	Borecole or Kale	Borecole or Kale
<i>Chou-rave</i>	Turnip-Cabbage or Kohl-rabi	Kohl-rabi
	Turnip-rooted Cabbage or Swedish Turnip	Ruta-baga
<i>Chou navet</i>	Turnip	
<i>Chou-fleur</i>	Cauliflower	Cauliflower
<i>Navet, or Chou-navet</i>	Turnip	Turnip

L. H. Bailey, in "Garden and Forest."

EASTERN AND WESTERN LILIES.

THE Lilies of Asia and America, in addition to their capability of floral impressiveness, have this valuable qualification—that the grandest of these bloom between the first and the second efflorescence of the Rose. This is an admirable arrangement for our gardens, and we do not greatly mourn the temporary absence of their greatest rival, while the imperial Lilies of Japan, of California, of India, and of Levantine regions are in splendid bloom. The earliest Lily and the latest—*Dahuricum* and *speciosum*—are, however, beautiful contemporaries of the Rose. The former flowers in the beginning of July, often as early as the third week of June; it belongs to the sub-genus *Isolirion*, its finest varieties being *D. erectum* and *D. incomparabile*, of which the latter, which increases rapidly, creates in my garden magnificent effects. With *Lilium speciosum*, on the other hand, the season of flowering is, as I have indicated, the latest of all; it is the peculiar glory of September and October, at which period it is undoubtedly, by reason of its beauty and fragrance, the most attractive of autumnal flowers.

In Scotland, the reign of that queen of the garden *Lilium candidum*, begins usually, except in an abnormally warm season, about the middle of July; and there can be no question that when it is extensively and adequately cultivated, the effect of this Lily when in flower is unique. By many authorities, such as Mr. J. G. Baker of Kew, Sir Edwin Arnold, who has travelled much in the East, and Dr. Wallace of Colchester, it is conjectured that the words "even Solomon in all his glory was not arrayed like one of these" were suggested to the greatest of Teachers by the brilliant aspect of *Lilium chalcidonicum*, the scarlet Martagon; but as *Lilium candidum* is also a native of the Levant, and flowers with great freedom in the valleys of Palestine, it is equally possible that its beauty may have been the inspiration of one of the most touching and memorable utterances of the "Friend of Man."

The amateur cultivator who knows nothing, in most instances, of their nature or characteristics, will, in all probability, during the first flowering season after planting their bulbs, be intensely disappointed with the aspect of these; but if he will let them wisely alone till the following year, he will witness a vast improvement in their growth, which in succeeding seasons will be greatly increased. It is, indeed, a peculiarity of all the Martagons, including *L. dalmaticum* and *L. chalcidonicum*, that as a general rule they take several years for their full establishment; but as I can testify from long experience, they are all the more enduring by reason of this limitation, if such it may be called, in the light of its results. *L. Szovitzianum*, sometimes erroneously denominated "the Persian Lily" (though, as I have already explained, this special variety is of Caucasian extraction, see *Gardeners' Chronicle*, p. 320, September 19, 1896), is a supreme favourite of the Dean of Rochester, in whose antique garden it sometimes attains to a height of 8 feet. Here, my stateliest specimen was destroyed, or rather, broken off from the bulb by the wind in the month of June, before which my finest Dalmatian Martagon also gave way—likewise a fasciated form of *Lilium candidum* bearing upwards of 100 buds. Growing as they were, in strongly sheltered positions, and none storm of such violence having been anticipated, they had been, unfortunately, inadequately secured. But I have this consolation, that the uninjured bulbs remain with what may be entitled their floral potentialities.

The growth of *Lilium giganteum*, the great Himalayan Lily, is like that of the Martagons, exceedingly slow when it is grown from offsets, as to ensure its full stature it always ought to be. One of my *giganteum* has been growing steadily thus for at least three years, and I anticipate that my patient will be amply rewarded next season by its floral revelation, and the majestic height to which, under such conditions, it will certainly attain. Perhaps the most successful cultivator in Scotland of *Lilium*

giganteum is J. W. Osgood H. Mackenzie of Inverewe in Ross-shire, not far from Loch Maree, and he tells me he grows it entirely from offsets, the results of which natural method of culture are invariably impressive. He who grows it from bulbs generated elsewhere than in his own garden need not be surprised if its growth is limited; likewise, let me add, the number and dimensions of its flowers.

The characteristics of *Lilium auratum* are of a widely different character from those of *giganteum*, for a bulb of this Lily, if planted as late as the end of February, will make, in all probability, a successful effort to bloom the same year. But I think that this is the experience of cultivators of the "Golden-rayed Lily,"—that, when grown in this somewhat disrespectful manner, which is utterly unworthy of a true lover of flowers, it has a strong tendency to resent such treatment, and disdains to exhibit, when its flowering-period comes, its full capabilities. The probability also is, that if forced in this unnatural manner, the result will be deterioration and early decay. The Divine Art, which works in the realms of Nature in its highest operations, is deliberately slow. Its loftiest work is accomplished imperceptibly. We do not see our fairest flowers growing, we only know by observation that they have grown. Their silent yet realisable evolution is a mystery, and so, by reason of our mental limitations, it must evermore remain.

Much might be written regarding the fragrance of Lilies, which imparts to our gardens such a tropical atmosphere during the summer and autumn months. The perfume of such varieties as *L. auratum*, *L. longiflorum* Harrisii, and even *L. candidum*, is too powerful and oppressive for an ordinary conservatory; but it is not objectionable in the open air. On the contrary, when experienced under such mitigating conditions, it forms—especially in the case of *L. candidum*—no inconsiderable part of their attractiveness. But on the other hand, the exquisite odour emanating from *Lilium Browni*, *L. Krameri*, and the richly-dowered *L. speciosum*, requires no mitigation. This, independently of their distinguished beauty, gives them a fascination which is, even among Lilies, exceedingly rare. David R. Williamson, *Manse of Kirkmaiden, Wigtownshire, N.B.*

NURSERY NOTES.

MR. G. MOUNT'S NURSERY, CANTERBURY.

As an instance of successful nursery and market gardening, Mr. G. Mount, carrying on operations at Canterbury and Folkestone, is worthy of a note in these pages. The original establishment, called the Exotic Nursery, in St. Peter's Street, Canterbury, once carried on by the late W. Masters for many years, and subsequently by him in company with J. Kimmont, still exists as an appendage of the larger nursery at St. Dunstan's on the outskirts of the city; but it is too small in area and too much surrounded by houses and trees to serve any very useful purpose at the present day. At one time this small nursery was filled with hardy perennials, hardy Ferns, Phloxes, Carnations, Hollyhocks, &c.; the walls with climbing plants, and the glasshouse with a fine assortment of Azaleas, Camellias, and stove and greenhouse plants, and the best Orchids of the day, exotic Ferns, and Selaginellas. The chief use of this garden at the present day is the growing of flowering annuals and border flowers for the shop trade, and Carnations and Picotees. The old circular-shaped glasshouse, standing in the centre, and once surmounted with an expensive domed roof, now replaced with one of a less ornate character, was filled, at the time of our visit, with Palms, &c., for decorative purposes. One longed to clear away the whole stock of the place, houses and all, and remodel and plant it with a better class of material, building a light useful glasshouse or two for the display of popular flowering and foliage greenhouse and stove plants. Perhaps, in time, the present proprietor, who is certainly not lacking in enterprise, will see his way to do this.

At the St. Dunstan's branch all is modern—

long, span-roofed houses of simple construction, and provided with ample means of ventilation and heating, are grouped together in some numbers. Here Vines and Tea Roses in pots are grown to perfection, also Tea Roses planted out for the supply of cut flowers all through the season, and now, being rested by withholding water from the borders and affording the most ample ventilation, to be started later in the autumn for furnishing flowers at Christmas, when there is a lively demand for Roses, especially Teas. The varieties chiefly planted are Niphetos and Catherine Mermet. This Rose-house measures 20 feet in width by 100 feet in length, and the area is divided into a central bed, and a bed at each side, and the plants are mostly in bush form.

Two other span-roofed houses were remarked, 135 feet in length and 20 feet wide in each case, that were similarly planted with Rose Catherine Mermet.

A large span house was filled with Maidenhair Fern, shade being afforded by training Tomato-plants to the sash-bars—a remarkably healthy lot of plants, both of Ferns and Tomatoes. Tomatoes in the perfection of health and fruitfulness occupied two houses, respectively 130 feet by 27 feet, and 130 feet by 20 feet. The plants were planted out, as we thought, rather thickly, in the central and side-beds. The results, however, dissipated any doubts that we may have had in respect to the plants shading each other, and thus acting inimically on their flowering, for more fruitful plants could scarcely be found anywhere under entirely dissimilar treatment. The fatal "spot" disease of the fruit, *Cladosporium lycopersici*, seldom gave trouble; and equal freedom from the leaf and fruit disease, *Cladosporium fulvum* and the "sleepy" disease was, we were informed, enjoyed. The *laissez faire* of some cultivators does not hold here, timely precautions being taken by dressing the plants with the Bordeaux Mixture, and affording as much air day and night as is commensurate with fairly rapid growth; moreover, the syringe is not frequently employed, nor much root watering, but the happy medium aimed at between a too dry and a too moist condition of the soil. The variety is a selection of Perfection, and hundreds of mature fruits were seen which measured 14 to 15 inches in circumference. Several thousands of *Chrysanthemums* Lady Selborne, one of the best white flowered decorative varieties, the plants healthy and well-foliaged, were remarked. The blooms are for cutting. *Maréchal Niel* and other climbing varieties of the Rose, are grown in pots; besides bushes of Tea Roses, similarly grown, were to be observed standing outside in the full sunshine, in order to mature the shoots. The second flowering of these and of the Tea Roses in the open quarters, had been very abundant this season, and still gave promise of a plentiful crop should the weather prove propitious, and early frosts in this part of Kent are not usually of any great severity, so that the promise will probably be fulfilled.

The large stock of *Chrysanthemums* above-mentioned will be accommodated in those houses that are now filled with maturing crops of Tomatoes, the pot-Vines, pot-Roses, &c.

Some remarkable quarters of young Apple-trees, one and two years from the graft or bud, were observed weighed down with fruit. These consisted of that wonderful cropper, Bismarck, the coming Apple for market purposes, according to the belief of many nurserymen; Worcester Pearmain, Cox's Pomona, Cox's Orange Pippin, Gascoigne's Seedling, Mère de Ménage, Peasegood's Nonsuch, Jubilee, and Blenheim Orange Pippin. All of these varieties are worked on the Paradise stock. We could not fail to remark the healthy appearance of all varieties of Apples, Plums, &c., and the entire freedom from aphids, and of the "worm i' the bud," Winter Moth and Codlin Moth, a pleasant state of things which is due to spraying the trees several times with Paris Green for the larvae, and quassia for the aphides. Of Plums there are great breaks of Rivers' Early, Denyer's Victoria, and various Gages: many of the trees being in bearing condition, and all were in a vigorous condition.

It was a genuine pleasure to us to observe in this

nursery a desire to keep abreast of the newer knowledge and methods whilst retaining all that is of value in the old. Especially was this to be noted in the use of fungicides and insecticides, the lamentable effects of the non use of which are only too common, even in such a famous fruit growing county as Kent.

MESSRS. H. CANNELL & SONS.

We have referred on several previous occasions to the work carried on at Eynsford by Messrs. H. Cannell & Sons, with a view to raising in this country flower and other seeds that are still imported largely from the Continent, and which a few seasons ago were obtained exclusively from foreign sources. Taking advantage of a bright day during the present week, we revisited the establishment, to see what the harvest of such seeds for the present year promised to be. Most gardeners are probably aware that Eynsford is the next station below Swanley Junction on the London, Chatham & Dover Railway; that it lies pretty high, and that the ground where the tender annuals are grown for producing seeds is a valley with steep sides very much exposed to light and all possible sunshine. Hence the position has been chosen for the purpose to which it has been put, and in this sense is exceptional. But there are numerous other spots, we doubt not, in Kent and the adjoining counties, where the work might be done as well as here, if commenced under energetic management. The results of the present season are not required to prove the capacity of our land or climate to produce seeds that English seedsmen have habitually permitted Germany to supply them with; for several years past this has been a fact to some of us. It would be mere affectation to pretend other than satisfaction at every fresh evidence English producers exhibit of a desire and ability to raise or manufacture for themselves an article, the supply of which they have heretofore obtained from outside sources. This much is said without the least intention to despise foreign produce, upon which we are continually dependent, and for which the country is grateful. If there is any gardener or seedsmen who doubts the capacity of our own climate to perfect seeds of all sections of Asters, he should run down to Eynsford during the next fortnight. The evidence Mr. Cannell will be able to give him should be conclusive, and it will be afforded freely.

Asters—The breadths of these Asters may be seen at present with blooms in perfect condition, others going to seed, and with some seed already developed. Of course, when this last stage is reached the flower-stems are removed, and then exposed to sunshine under glass. Thus the Comet section had been removed altogether, as it is the first to be harvested. Other types were still in the field, including Victoria, Emperor, Pæony-flowered, Crown, Shakespeare, Mignon, Jewel, English Quilled, Comets, Needles, &c. All of these, and indeed every description of Aster, we were informed, produce capital seed at Eynsford, and of all, except novelties, the stock in the nursery is raised from seed so obtained. Owing to the construction of the flowers, the most difficult to seed are the Pæony, Victoria, and Emperor types; the most easy being the quilled flowers, which have always been grown as well in England as anywhere. Mr. Cannell assured us that sufficient seeds of every section are obtained to supply the whole of his private trade, and for planting again in the nursery the following spring. These seedlings are dibbled out towards the end of May or in June. It would serve no purpose to enumerate the very many varieties of different colour in all the sections, but the yellow-flowered variety of quilled Aster, known as Eynsford Yellow, may be mentioned as being decidedly distinct and the best yellow-flowered Aster. There is a novelty described as a yellow-flowered Victoria, but as we saw it, the flowers were only cream-coloured at the most. Speaking of novelties, there are several from the continent, including the Victoria just mentioned; *L'Idéale*, a white-flowered Aster with smooth petals, excellent flowering habit, so that when pulled up the plant forms a fine white bouquet in itself. In shape and size of flower, it looks like a rather large Mignon. X-rays

represents two varieties, one white-flowered, the other purple; the florets are quilled, and the blooms pretty fairly represent some of the Japanese Chrysanthemums.

MISCELLANEOUS.

Most of the Stocks, including the biennial ones, are grown in pots, and being flowered under glass, the perfecting of the seeds is ensured. Turning from the Asters, there are beds around of various flowering plants, all being grown to produce seed. African and French Marigolds, Dianthus, Lobelias, Salpiglossis, Violas, Verbena hybrida (an excellent strain with extra large flowers), Nasturtiums, Phlox Drummondii, Petunias, Antirrhinums, Delphiniums, Carnations, Pentstemons, Godetias, Coreopsis, and too many others to be mentioned here.

Owing to the dry weather during the summer, the seed-harvest is rather earlier than usual, and should the present bright sunshine continue for a fortnight the quantity and quality of the seed will be most satisfactory. A white, single-flowered Petunia named Snowball, a Continental novelty, was very promising; as was a semi-double variety of dwarf Lobelia, named Duplex, with flowers of intense colour. In the bottom of the valley many beds of Violas were still flowering freely, among them being a fine yellow one, named Christina Robinson, raised at home, which we think gardeners will value.

Vegetables, not less than flowers, are planted in the nursery and adjoining fields to produce seeds, and excellent Parsley, Lettuce, and other kinds, may be seen close to the Asters. Onions are successfully grown and seeded, the large breadth covered with bulbs to flower next year being in every way satisfactory. A stock of exhibition-sized bulbs has been housed, of excellent quality, being sound and fully ripened.

When the numerous features in the seed-grounds have been studied, the houses where the seed-drying is effected may be visited. They stand on a hill, are span-roof and light—just the kind suited to Melon, Cucumber, or Tomato-growing, to which purpose they are put during the summer. Now, however, they are full of seeds, principally of flowering plants, and no better place could be desired to thoroughly dry and ripen them. Leaving the wonderful seed-farm, the management of which must require unremitting care, industry, and patience, we are driven back to

SWANLEY,

but by a round-about way, for the purpose of noting two systems of fruit-growing, the lazy method, and the up-to-date intelligent method. We are not concerned with this at the present, however, and reaching Swanley, there was plenty to interest one for a very long time. The zonal Pelargoniums, and other plants for winter-blooming, are looking capital. Three houses were occupied by Cannas, and one of these especially presented a gay picture. Cannas are obtained in bloom the whole year round, and at the present there are numerous varieties in fine flower. We will mention a few extra good ones that any gardener may obtain with confidence that they will please:—Aurora, orange-scarlet, a well-formed flower, habit of plant dwarf; Germania, scarlet, with a suspicion of yellow towards the margin of segments; the well-known Queen Charlotte, an excellent variety; American Flag, orange-red, with a yellow fringe; Beauty Poitevine, vermilion-crimson; Persoa & Co., crimson; Emilie Lorenz, very fine, a dwarf plant, with a compact inflorescence, flowers yellow, marked with blood red; Incendie, similar to the last-named, but the colours less decided; Souvenir de Antoine Crozy, Alphonse Bouvier, intense crimson; M. H. Debrousse, spotted yellow, habit very good; Madame Pichon, yellow, with suffused red spots; Madame Perrin de Isles, quite a new shade of colour, perhaps best described as red, over which is a silvery hue, and suspicion of purple—a first-rate novelty; and Madame La Baronne P. Thenard, also a new shade, being distinct orange. The two last-named are acquisitions.

MESSRS. J. CHARLESWORTH & CO.

The collection of Orchids obtained by E. H. Woodall, Esq., St. Nicholas House, Scarborough, has passed into the hands of Messrs. J. Charlesworth & Co.,

Bradford. The collection is famed for its fine specimens, and the remarkable varieties it contained, many of which have from time to time delighted the visitors to the Royal Horticultural Society's shows. Among them may be noted some grand examples of Vanda corulea, one of which secured a First-class Certificate; a fine specimen of Cypripedium insigne Sanderae, the rare, scarlet-flowered Renanthera Irmschootiana, Cypripedium Rothschildianum giganteum, C. Leeannum giganteum, and some remarkably fine Cattleyas and Laelias, among which are capital specimens of Laelia crispa superba, and Cattleya Loddigesii, sent direct to Mr. Woodall by desire of the late Emperor of Brazil.

Messrs. Charlesworth & Co. have also acquired the collection of M. Robinow, Esq., Hawthornden, Didsbury, Manchester, a Guatemalan merchant, who had exceptional facilities for procuring the best varieties of everything from the countries in which he had correspondents; hence his magnificent specimens of the best form of Lycaste Skinneri alba, and other rare varieties. The collection, which has been carefully worked up for the last twenty years, contains Gramatophyllum speciosum, Coelogyne cristata alba, in fine condition; Vanda Sanderiana, and other showy Vandas and Aerides, and many rare species. Both the late owners are giving up their collections, owing to indifferent health rendering it inconvenient to afford their hobbies the proper amount of attention. J. O'B.

KEI-APPLE AS A HEDGE PLANT.

THIS shrubby South African plant (Aberia caffra, Harv. & Sond.), a Bixiaceae plant, is armed with long spines, and makes excellent hedges. It is evergreen, and bears fruits like small yellowish Apples. When fresh they are acid, and used as a pickle; when ripe they make a good jam. The *Waikato Times* of New Zealand, recommends the Kei-apple as a hedge plant in the following terms:—

"One is always hearing complaints now-a-days of the paucity of good plants suitable for hedge purposes. This harbours the Wheat-rust or the leech, but dies out in patches; while another would be admirable were the cows not so fond of it. This being so, the thanks of the community are due to Mr. A. Tempest, of Parnell, for his enterprise in introducing and propagating the Kei-apple. It was Sir George Grey, I believe, who first mentioned the shrub, which grows wild upon the Karoo, or sandy plains of South Africa, and it certainly seems a perfect hedge plant. It is a sturdy, stocky, short-jointed grower, an evergreen, and with thorns which grow to 6 inches long and over, and a 'perfect terror to evil-doers,' be they beasts or human beings. As an added advantage, the female plants (they are of both sexes) fruit heavily, bearing in great quantity yellow Plum-shaped fruits, the size of a Green Gage, which are both pleasant eating, and make an exquisite jam. Orchardists would do well to bear this shrub in mind when planting."

To this the following note is added in the *Agricultural Journal* of the Cape of Good Hope:—

"It will be noticed that a wrong part of the country is stated to be the native habitat of this plant, but all the good qualities as a hedge plant are perfectly true. In some old book of travels in South Africa, it is stated that on the eastern coast there were 'wild Apricots'; were these Kei-apples? Few people like to eat the fruit raw, but the jam is first-rate. A proportion of Kei-apple, with Tomato, would make a good jam."

THE WEEK'S WORK.

PLANTS UNDER GLASS

By G. H. MAVCOCK, Gardener, Luton Hoe Park, Luton.

Indian Azaleas.—Thoroughly cleanse the structure in which it is intended to house these plants, as they will require to be taken indoors very soon. The plants themselves should also be cleansed with a solution of soft-soap and tepid rain-water, or by the use of some safe insecticide. To effect this, lay the plants on their sides to prevent the liquid from entering the soil. Immediately the plants are housed and dry, well fumigate the house for the purpose of killing any thrips that remain.

Ivy-leaved Pelargoniums.—These may be propagated, placing four or five cuttings in a pot. Keep them in a cool-house, and rat at the root, until roots have formed. They be potted off as soon as they are struck, growing all the winter; thus treated they would good decorative plants by next season.

Chrysanthemums.—Vigilance will be required down earwigs, or they will prey upon the selected to form the early supply of bloom. all lateral growths, and see that the plants suffer from want of water. The surface of may appear moist when the roots are not, rap every pot carefully with the knuckles the matter. Preparation should be made for the plants, that, should early frosts occur, they may be removed under cover expeditiously.

General Work.—All other plants that were outside for the summer months, will need removed to the houses very shortly. If it ticable to devote small houses to some of the cial species, the work is greatly facilitated. case, no plants should be housed that thoroughly clean. The houses, too, should be cleansed for their reception; the creepers thinned out, as the case may require, and pests destroyed. If the plants have to be housed containing mixed collections, the arrangement should permit of the different species being separate groups.

THE HARDY FRUIT GARDEN

By H. W. WARD, Rayleigh, Essex.

Transplanting Young Fruit Trees.—In most young trees of the Peach, Plum, Pear, &c., are temporarily till space on the walls and in borders and orchards, can be found them. By following this plan the trees in time size, and the foundation of the future besides getting well provided with roots prepared trees do not feel removal much away the following summer unchecked is especially if they are transplanted in the before the leaves fall, that is towards the next month. In order to transplant satisfactorily, they should be lifted with of the earth adhering to the roots, as of the fibres intact. The soil for 18 to 2 feet from the stem of wall-trees, and distance, or a little more, according to size case of trees growing in the open, should be over with a fork, and watered a day or two digging up the trees, so as to insure the operation. On beginning to dig up a tree, should be opened out about the distance more or less, according to the size of tree about the same depth, the soil being carefully with a fork from beneath the roots until the of the mass of soil is reduced sufficiently. two or three men to lift it on to a strong gal which should have been placed under the b it is still in its place. By this means the be readily lifted without the soil coming a the roots. The hole at the new station of should be a little larger than the ball, and prepared in readiness for the tree. If the good, i.e., loamy, inclining to be heavy rat light, and about 18 inches deep, all that sary is to excavate the hole to the prop breaking up the soil in the bottom of the a fork, and placing a portion of the top spi leaving the soil somewhat high in the for a standard or bush tree, rounding off to for wall-fruit trees. Being satisfied that the deep enough to take the mass of soil without burying the crown of the root mor inch, place the mass in the hole, rest mat from beneath the ball, cut off strag damaged roots, and work some of the under and among the roots protruding from of the ball. In planting, allowance should for the soil subsiding 1 or 2 inches in t of as many weeks. When the soil filled in round the ball, mulch with a 2-inch short dung, and afford the whole a thorough tion of water. If the staple be poor, shallow for near the water-line, means should be render it better adapted to the requirements tree by adding thereto road-side parings th and horse-droppings or short dung one whole being well mixed before being p hole. In the case of wet land 6 inches of c brickbats should be put into the hole for and the trees planted on slight mounds. event of the staple being unduly heavy,

chalk, lime-rubble, or leaf-mould, if obtainable, should be added; lime-rubble and leaf-mould applied together would prove beneficial. Trees of the Peach, or choice varieties of the Plum and Pear, transplanted to sites against walls having south, west, and east aspects, will be the better for having a mat or two hung over them during the heat of the day for a week or ten days after removal, syringing the trees overhead in the afternoon.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Spring Cabbage.—The crop of Spring Cabbage being usually regarded as an important one, the early cutting of which affords a good deal of emulation to the craftsman, every effort should be made to push on the plants at this season. The plantations of the earliest-mixed plants should be hoed on a dry day, and after lying untouched for a day or two, the plants earthed-up with the hoe. The main batch of plants of the principal sowing will now be large enough for planting on the ground occupied by the Onion crop; the soil if it be light and in good heart, being merely dug over slightly, or deeply hoed, and the rubbish raked off. In most cases, however, it will be advisable to afford the land a light dressing of good manure, and dig it. Too much space between the plants is not desirable, and 18 inches each way is sufficient for all the early varieties of Cabbage. If slugs be troublesome, dust the land with soot and lime, doing this in the evening or early morning, and fill up vacancies in the rows without undue delay.

Endive and Lettuce.—If well-rooted stocky plants are still to be found in the seed-beds, they may be dibbled into the soil of a south or other warm border, planting them at 15 inches apart, and keeping a sharp look-out afterwards for slugs and grubs of various kinds, creatures that are very fond of newly-planted Lettuce. This batch of plants will prove of great use during the last two months of the year, if means can be afforded to shelter them where they grow from frosts and heavy rains. If frames or pits are available at that season, the plants, when fully or partially grown, may be planted in these rather closely, and given proper attention in the matter of airing, they will remain fit for use for a long period. Lettuce-seed may still be sown in a sheltered plot of ground for affording plants for setting out in the early spring; Bath, or Brown, and Hicks' Hardy White Cos, and All the Year Round Cabbage being the best varieties to sow at this season.

Mushrooms.—Endeavours should be made to supplement the supply of Mushrooms obtainable in the fields and from Mushroom-beds in the open, by making beds in the Mushroom-house or in warm sheds. In making up beds in sheds it is necessary at this time of the year to make them thicker than is necessary in warmer weather, and after spawning them, which should be done as soon as the heat has declined to 85°, to cover the bed with a good thickness of sweet hay or dry litter. If the supply of fresh horse droppings be insufficient, fresh tree leaves may be mixed with the manure, in the proportion of one of leaves to three of manure, or dry loamy soil in about the same proportion may be used instead, taking care to mix all thoroughly together a few days before making up the bed.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maidenhead.

Rows.—Blooms promise to be more plentiful than was at one time anticipated, the rains having induced free growth, which is clean and free from rust and mildew, so far. Briar-stocks that broke too late into growth for the first budding may be budded if the bark runs easily. These late buds if they take well remain dormant till the spring, which is better than having buds break into growth, which being tender when the winter comes, is liable to be cut off by frost. The buds on early worked Briar-stocks should have the ties round the buds loosened or removed, as may be necessary. The strong shoots on climbing Roses should be loosely tied in, or they may be broken off by winds; and all weak and blind shoots, and the shoots that have borne flowers, clean cut away. This will strengthen those that are left, by letting in the light, and utilising the energies of the plants in the right direction.

Propagation.—Cuttings of *Coleus*, *Alternanthera*, and *Resinas* for furnishing stock in the spring, should now be taken from the plants in the beds, and inserted in pots of sandy soil, surfaced with silver sand, and plunged in a mild hotbed to form roots. The cuttings of *Mesembryanthemum cordifolium variegatum* being liable to damp off in a hot

bed, can be struck with the least amount of loss if the cutting-pots are placed on a shelf in a warm house that is kept moderately dry. Having watered in the cuttings, the soil should be allowed to get rather dry before water is again afforded, and all decaying cuttings removed as soon as they are observed. Cuttings of *Fuchsias* may now be struck, and in the case of bedding varieties, they may be kept growing till next spring, either in the cutting-pots, or as potted-off plants. *Fuchsias* form good subjects for filling vases and baskets, as well as "starers" or solitary plants in the beds. The bedding *Pelargoniums* have made moderately sturdy shoots which will make capital cuttings should more stock be required to meet the requirements of next year. The cuttings at this late part of the season must be rooted in pits, or frames, and not out of doors. *Calceolarias*, *Violas*, *Geranias*, &c., may remain until quite the end of the month, with the certainty of the cuttings striking freely at that time.

Carnations.—The layers, if well attended to from the first, will have become sufficiently rooted to allow of severance from the parent plant and planting where they are to flower next year, or for potting and keeping in cold frames during the winter. In all but the very coldest parts of these islands and in smoky centres, border Carnations are best outdoors, and especially if the soil be light. In clayey and wet soils, winter protection is often necessary; but the less codling, as a rule, the plants receive, the better. The beds and sites for receiving the layers should be changed annually, and should be prepared by digging and manuring, new loam or decayed manure, or both, forming a good dressing for the beds or patches. After making the soil firm by treading it evenly and regularly all over, and in the case of beds lining them out in quadrangular shape, plant out the stronger and better-rooted layers at one foot apart. Potted plants should be made firm in the soil, and afforded an abundance of air always, except during hard frosts.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Odontoglossums, &c.—Where these plants are cultivated largely it will take some considerable time to get them all repotted, and while this work is in progress, other plants will be requiring similar attention. *Lælia elegans* now flowering from the new pseudo-bulbs should be repotted, if necessary, as soon as the flowers fade, the new roots at that time emitted from the base of the flowering-bulb, enabling the plant to establish itself. Afford plenty of drainage in the pots, and a thin layer of sphagnum-moss over the crocks; and use fibrous peat and sphagnum-moss in equal quantities, mixing plenty of small clean crocks with it. When repotting any tall-growing species of *Lælia*, make the pseudo-bulbs firm by fastening them to a neat and durable stick, and keep the base of the plant above the rim of the pot. At this period some of the plants are in bloom, others fast sending up bloom-spikes, the young pseudo-bulbs being especially tender and subject to decay from water lodging in the centre of the growths, too great moisture in the compost, or a too low temperature; or excess of moisture in the atmosphere will also cause the leaves and bulbs to decay. If injury arises from excess of moisture at the root, forthwith repot the plant and place it in a drier and warmer house. If caused by the other evils, which are only local, the affected pseudo-bulb may be removed almost to its base, affording water with care afterwards, and gradually exposing the plant to more light and air. If a plant exhibits no further signs of discoloration, it will commence to root, and may then be repotted in the manner advised for healthy plants. A newly-potted plant of *Lælia elegans* requires careful watering, as any excess causes the tips of the roots to become black. First afford as much water as will moisten the compost, and subsequently less frequently, and gradually diminish the quantity according to the activity of the roots. At the present time, and during the winter, the plants of this species should be placed at the warmest end of the Cattleya-house, or where the warmth is about 60°. Our late-flowering plants of *Lælia purpurata* are starting into growth, and any that require repotting will be attended to when the growths are a few inches high. Large specimens that may have lost many old back pseudo-bulbs may be divided and remade up; decayed portions of the rhizome, dead roots, being removed, and the worn-out compost replaced with new. *L. purpurata* requires a deep pot and plenty of compost. The varieties of *Cattleya Eldorado* may now be repotted. Keep them in the warm part of the Cattleya-house, and when the night temperature of that house

falls to or below 60°, place them in the cooler part of the East Indian-house. *C. Bowringiana* which has ceased to grow, does not need frequently to be afforded water, the pseudo-bulbs turning black, and the inflorescence being lost if too much moisture be afforded. This applies also to plants of *C. Skinneri*, *Cattleya Dormaniana* and *C. bicolor*. *C. Lawrenceana*, *C. exoniensis* ×, *C. amethystoglossa*, *C. elongata* (Alexandria), and *Lælia tenebrosa*, now in good growth, will be benefited if placed at the warmer end of the house and raised to the roof. Small plants being suspended from the roof, will assist in the timely formation of the new pseudo-bulbs. *C. Dowiana* and *C. D. aurea*, now in bloom, should be placed where they can get plenty of light to ripen their growths, water being carefully afforded. *Lælia pumila* and its varieties should be hung up to the roof of the Cattleya-house, plenty of water being afforded them till the flowers fade, and growth for the season is at an end. *Cattleya Trianaei*, *C. Mendeli*, *C. Schroderae*, *C. Percivalliana*, *C. maxima*, *C. labiate* (the autumn-flowering variety), and others which have ceased to grow, will require less water at the root, every ray of sunlight, and as much fresh air as it is practicable to give them. During the dull damp weather it is advisable to look over the *Cattleyas* and *Lælias* every morning, letting out the moisture that gathers in the sheaths, which, if not removed by slitting those that are damp-looking, will cause decay. The plants so treated should be kept dry at the root, and removed to a drier house for a few days. If a pseudo-bulb is seen to be turning black, the plant should be treated as advised for *Lælia elegans*.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Ledbury.

Tomatos.—Plants which have borne much fruit should be removed, and new plants for winter-fruiting planted in their places. These plants should have been setting their fruit outdoors, but it being risky to allow them to stay there any longer, it is well to plant them forthwith under glass. The house or pots, before the plants are placed in them, should be cleaned and fumigated, and if the Tomato-fly has been a source of trouble, flowers-of-sulphur may be burned in them, or Richards' XL All employed in its place. The proper drainage of the beds is an important matter, and this must be examined, and if found faulty, put in good order. Be careful in fastening the plants to the trellises that the stem does not get twisted; and rub off all laterals, so as to allow of the plants being stood nearly close together. If the plants are already in their winter quarters, the roots must not be allowed to ramble at will, but they must be confined or restricted in some way. It is always advisable to set the blooms, if possible, out-of-doors, the conditions favouring setting during the fine days in early September. The redundant growths of shoots and leaves on fruiting plants should be regularly reduced, so that light may reach the ripening fruits. Afford water rather sparingly, and ventilate freely in fine weather, and gather the fruit as soon as it is well coloured. Gather all fruits on out-of-doors plants if frost appears imminent, hanging them in a warm glass-house to ripen.

Pinery.—No time should now be lost in getting the various divisions put in order for the winter, washing the walls, &c., with soft-soap and water in which half-a-pint of petroleum to the pailful is mixed; not forgetting when washing the walls to wash those of the pit that will contain the fermenting materials for bottom-heat. If tree-leaves in a fresh state are used at this season, great care must be taken that the plants do not suffer from any excess of heat in the bed, fresh leaves being very liable to heat violently, which, if it happen when the bulk of the plants are resting, would be very disastrous.

Fruiting Plants carrying fruit will require a steady bottom-heat of 85°, and to be examined carefully once a week to ascertain if any plant requires water at the root, water being afforded a plant till the fruit it is carrying begins to colour, and then withheld.

Succession-plants, which have quite, or nearly finished their growth for the season, should be kept in a moderately dry condition at the root—not too dry, or they may fruit prematurely. The bottom-heat should not exceed 80°, or the night temperature 62°.

Snakers which have made free growths, and are likely to get pot-bound before the spring, may still be repotted into comparatively small pots. Advantage should be taken of the first warm day to wash the walls and glass of all pits and houses containing Pines, even should the occupants of the same need no immediate attention.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	SEPT. 21	Royal Horticultural Society's Committee.
SALES.		
MONDAY,	SEPT. 20	Bulbs, at Protheroe & Morris' Rooms.
TUESDAY,	SEPT. 21	Bulbs, at Protheroe & Morris' Rooms. Clearance Sale of Glass Erections, Piping, &c., at the Layfield Nursery, Sudbury, Harrow, by Protheroe & Morris.
WEDNESDAY,	SEPT. 22	Bulbs at Protheroe & Morris' Rooms. Clearance Sale of Glass Erections, Piping, &c., at the Rose Nursery, High Street, Clapham, by Protheroe & Morris.
THURSDAY,	SEPT. 23	Bulbs at Protheroe & Morris' Rooms. Sale of Palms, Ferns, Shrubs, &c., at the Floral Nurseries, Castle Hill, Maidenhead.
FRIDAY,	SEPT. 24	Bulbs at Protheroe & Morris' Rooms. Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—56.6°.

ACTUAL TEMPERATURES:—

LONDON.—September 15: Max., 67°; Min., 52°.

PROVINCES.—September 15: Max., 62°, at York; Min., 53°, at Sumburgh Head.

Do Orchids degenerate? THE report of the Congrès Horticole de la Société Nationale d'Horticulture de France, 1897, revives the question, "Do certain Orchids degenerate under cultivation?"—a question which has been frequently touched upon in the pages of the *Gardeners' Chronicle*. In speaking on the subject, M. GEORGES GRIGNAN made some excellent remarks, the tendency of which was to maintain that the question was by no means settled, and that, were it possible, it should be submitted to universal suffrage; and even then the matter would possibly be as indefinitely terminated as it is now.

We may say that we agree with the views expressed by M. GEORGES GRIGNAN; and as it is a matter of the highest importance to the large number of amateurs now cultivating Orchids, we venture to touch on the subject in the hope that some of our readers may be able, and willing, to give their version of it.

In the first place we should say that, in order to start fairly, the question should rather be put, "Do certain Orchids degenerate under cultivation more than other plants which are not easily propagated?" It may be said that all cultivated plants which are not readily increased by seeds, cuttings, runners, or in some other manner whereby the re-establishment of the plant as a young specimen, free from the infirmities of the old stock plant is secured, are liable to degenerate more or less quickly, the rate in a great measure being determined by the care bestowed on them, and the suitability or otherwise of their surroundings. It is not too much to say that plants, like men, must terminate their existence at some time or other, whether in their native habitats or under cultivation; and it is doubtful whether a huge mass of *Cattleya* freshly imported does not last as long as a single specimen in the Orchid-grower's hands, if it be properly treated, as it would be in its native habitat. But in its native home, when the feebleness of old age comes on, some of the stronger pieces on its outer circumference establish themselves as centres, and when the main plant collapses, they start anew as fresh plants. This process (a very common one among hardy perennials) is analogous to what is called degeneracy under

cultivation, and one of the methods of preventing the loss of the plants would be to imitate nature and start with fresh young specimens. This practice is much resorted to by nurserymen, and there are numberless instances of Orchids which were only imported as a single specimen, or in other cases as two or three specimens, and by propagation under cultivation, they have become tolerably plentiful, and more healthy to-day than was the first imported plant. One of the most familiar instances of this is *Dendrobium nobile nobiliss*, though that is scarcely a severe test, for the species is not generally on the black list, but still there are numbers of gardeners who do not succeed in growing it well.

And with regard to the list of species difficult to grow, it appears that what one grower considers difficult, another manages very well; and the genera which are considered impossible to cultivate to-day, may be as easily managed by those who understand them in ten years' time,

unsatisfactory, though here and there suffice specimens of them in rude health may be found to redeem them from the list of unmanageable which, generally speaking, means plants understood, or for which no proper accommodation has yet been found. Of these we mention *Saccolabiums*, *Aërides*, *Vandas*, and other evergreen Orchids of the same class with which the greater number of Orchid-growers fail, probably from the same cause: growers of the *Catasetums* failed in time gone by, viz., an excess of heat and moisture at the season, when, though evergreen, they require, in the same manner as the deciduous plants coming from the same districts, a resting season, though not necessarily a drying-off.

Cattleya Mossiae has by some means got the reputation of degenerating, though in some of our old gardens, where a few Orchids are grown among other plants, it is no uncommon thing to find great specimens of it, and of other reputed "bad doers," which have been in

FIG. 59.—A PLANT OF *NEPENTHES* X *TIVEYI*: PITCHERS COLOURED BROWN AND GREEN.

(Shown by Messrs. J. Veitch & Sons. See p. 201.)

as some of the things considered very difficult to manage ten years ago are easily grown to-day. Take, for example, the *Catasetums*, *Mormodes*, and *Cycnoches*, which up to a few years ago had a bad reputation as being unmanageable. To-day you may see in Sir TREVOR LAWRENCE'S collection, and in others, a large number of specimens which have been cultivated for years, and with increasing strength of flower and growth. The reason of this change will explain a large number of successes with plants that were formerly regarded as difficult.

Formerly, when *Catasetums* and other plants of the class alluded to were received, they were placed on the staging among other Orchids, and watered more or less all the year round, like too many other subjects which require a distinct period of growth, and as well marked a period of rest—and degeneracy and death were the consequences. Now, they receive special treatment, and are grown well, and afterwards they are properly ripened; the period of inactivity serving the all-important purpose of ensuring their doing but twelve-months' work in one year. There are yet many classes which are at present deemed generally

same garden for a great many years. In such specimens now are more often found gardens where a collection of Orchids is attempted than they are in collections almost exclusively of Orchids, and in which degeneracy is said to be noted. And this brings us to another thought as to the cause of the so-called degeneracy, viz., overcrowding. In the early days of Orchid culture small consignments were the rule, the specimens were carefully guarded and given space by the cultivators who received them, now the plants come over by the thousand, it is quite a common thing for amateurs to buy a hundred or so of a species at a time. The consequence is, that suddenly an amateur starts with new houses and plenty of room. In early days all goes well, for anyone can grow Orchids for a time; then, as large quantities are continually being added, the houses begin to get crowded, and the owner finds for the first time that Orchids are not so easy to grow as he thought, and that some of them are degenerating. The plants have the same nature as they had when they did well, the conditions are altered. The subject is an interesting one, and its bearings numerous.

FIG. 60.—PITCHER OF NEPENTHES X TIVEYI.

and in future issues we hope, with the assistance of some of our readers, to give particulars of some species of Orchids, of which the plants noted have been in cultivation for a great number of years.

But before leaving the subject, we would like to point out the importance of raising Orchids at home. To a great extent, so far, the experiments have consisted of raising cross-bred varieties, and our experience of these tends to prove that the home-raised plant has a better constitution, and can better adapt itself to our climate and houses than the imported specimens can be expected to do. The question is, then (although it would take time), would it not be wise to raise uncrossed, or true, many of the finer varieties of Cattleyas, Lælias, and other popular Orchids, and thus, while increasing the plants wished for, get also the better constitution which comes with the seedling plant raised in the country in which it has to grow?

It is true that disease, which many Orchid-growers attribute to unsuitable surroundings and errors in treatment, attacks Orchids in some collections; but it can no more be spoken of as either the cause or the effect of degeneracy, than the diseases attributable to unhealthy surroundings and errors in diet which afflict human beings can be said either to point to, or arise from the degeneracy of mankind.

NEPENTHES X TIVEYI.—Our illustrations represent a full-sized pitcher and the plant as it appears at the present time, of a new hybrid of *Nepenthes* raised by Messrs. J. VEITCH & SONS, of the Royal Exotic Nursery, Chelsea, and exhibited by them at the Royal Horticultural Society's meeting held at the Drill Hall, James Street, Westminster, on Tuesday, 7th inst. The plant is the result of a cross between the species *N. Curtisii* and *N. Veitchii*, and is named in honour of Mr. TIVEY, one of Messrs. VEITCH's able hothouse foremen. The ground colour of the body of the pitcher is of a light green, streaked and blotched with a bright brown tint, as is likewise the prolongation of the mid-rib of the leaf on which the pitcher depends. A conspicuous feature is the broad, convex rim of the pitcher, which is of bright reddish-brown, running into a lighter shade towards the inner edge, and beautifully lined. The operculum or lid resembles the rest of the pitcher in regard to the ground colour and markings; the wings are green, and possess a few long hairs. The pitchers in general partake of the characteristics of both parents—*N. Veitchii*, a Bornean species of great beauty, going sometimes under the names of *villosa* and *sanguinea*, and figured and described in the *Gardeners' Chronicle*, December 7, 1881; and *N. Curtisii*, also Bornean, introduced by Messrs. VEITCH through Mr. CURTIS and figured and described in the *Gardeners' Chronicle*, December 8, 1887.

THE CULTIVATION OF CYCLAMENS is the title of a lecture to be delivered at a meeting of the Committees of the Royal Horticultural Society on Tuesday next, in the Drill Hall, Westminster.

THE BRITISH ASSOCIATION.—The second Canadian meeting of the British Association, as we learn from the *Times* of Sept. 11, has come to an end. The general impression is, that in many respects it has been one of the most successful meetings ever held. In point of numbers it is, as might be expected, below the average; the total is 1860. But in the number and character of the papers, in several at least of the sections, the Toronto meeting will compare favourably with any recent meeting. In the Botanical Section the papers were almost all of a highly technical nature, dealing largely with the microscopical structure of plants. Mr. SEWARD's lecture on "Fossil-plants" was one of the most warmly received contributions to the work of the session.

THE CHURCH ARMY'S EMIGRATION TEST FARM.—The Earl of WINCHILSEA has joined the Management Committee of the Church Army as honorary adviser to the Society's emigration test farm and market garden. Mr. FRANK SPICKER, of Farnborough, has also become an honorary agricultural adviser.

THE IMPORTATION OF BELGIAN WITLOOF INTO FRANCE.—The importation of Brussels Endive or Witloof into France, according to the *Journal du Cercle Horticole du Nord*, has assumed large dimensions in recent years, and the greater part of the Witloof consumed in that country is of Belgian growth, there being, it is calculated, about a million and a half kilos. imported. The Halles in Paris and

and continues to increase its demands. The total produce of the champagne districts is some 28,000,000 bottles, and 22,000,000 are exported. In 1894 and beginning of 1895, the consignments to this country showed a falling off; however, a decided increase took place in the second quarter of 1895. While the quantity exported to us during the first five months of that year amounted to 3,252,000 bottles, it increased in the corresponding period of 1896 to 3,938,000 bottles. It is to be noted, that whilst the trade with America remains stationary, that with Russia, Germany, and Belgium shows an increase in proportion corresponding to that of our own. It would be interesting to our transatlantic friends if they could get at the actual consumption of

of low-lying fogs, the search-light which render them visible is an invaluable assistant. A year ago some accounts were published relative to the cloud effects on Mount Low and Pasadena. According to these accounts Mount Low is about 15 miles north-east from Los Angeles, and about 6 miles in a straight line from Pasadena. When the beam of light fell upon the bodies of clouds they at once became luminous, so that all the details of motion were visible; when the beam fell upon the falling rain, the great cone of light glowed like molten metal. It seems, concludes Prof. Abbe, that the formation and motion of fog and cloud at night-time could be advantageously studied by means of the search-light. The height at which fog first forms, and its gradual extension upwards and downwards during the night, would be a very interesting and profitable investigation. *Nature*, September.

THE CODLIN-MOTH.—Those orchardists who have but few Apples this year will have their compensation next year in the greatly lessened numbers of the Codlin-moth. It has been remarked that in orchards which had few Apples in any one year, the fruits were not greatly injured the following year, even when no measures were taken to prevent an attack. This was doubtless owing to the moth finding few or no fruit in which to develop the maggot.

ASPARAGUS RUST.—We remark in *Garden and Forest* for August 25, an article, with illustrations of a disease of Asparagus, appearing in the U.S.A., which takes the form of a rust, and is due to a fungus, *Puccinia asparagi*. The parasite is exceedingly minute, consisting of microscopic threads, which penetrate the tissues of the Asparagus plant, deriving its nourishment therefrom, and breaking through the surface to bear the innumerable brown spores that impart the dark colour to the spots on the stems. The Bordeaux Mixture has been used as a protection and preventive dressing. As a means of destroying the spores existing on the mature stems and leaves, collecting these and forthwith burning them, is an obvious way of lessening the risks of an attack of the fungus another year.

VALUATION OF NURSERY GROUND.—Messrs. T. KENNEDY & Co., of Dumfries, have successfully appealed against the valuation of their York Place Nurseries, at Dumfries, which was assessed at £60. The claim for a reduction to £40 was granted.

BELGIUM.—We published last week a few notes of the exhibition of the Antwerp Royal Horticultural Society. In addition to the Certificate of Rarity obtained by M. F. DE LAET, of Contich, for *Echinocactus Trolletii*, this exhibitor was awarded Cultural Certificates for *E. Wislizeni* and *Melocactus communis*, a Gold Medal for a group of Cacti, and for another group a silver gilt Medal.

PUBLICATIONS RECEIVED.—*Kew Bulletin* for August and September. Diagnoses Africana, embracing 181 species of plants; also a few miscellaneous notes.—*Dictionnaire Iconographique des Orchids*, by A. COGNIAUX and A. GOOSSENS: Epidendrum.—*Florilegium Harlemense*. Coloured plates, with descriptions of bulbous and tuberous-rooted plants.

A "CRESTED" BEGONIA.

DURING the present year we have on several occasions, given illustrations of "crested" Cyclamen flowers, and in fig. 61 is reproduced a bloom of a tuberous-rooted Begonia shown at the last meeting of the Royal Horticultural Society, from the gardens of Sir Trevor Lawrence, Bt., Dorking. Mr. Bain writes us: "I cannot yet say much about the crested Begonias. Sir T. Lawrence has half a dozen varieties of them in different colours, and showing crests of different degree. By saving seed from the best crested varieties, I hope to obtain flowers with larger crests. The varieties appear to retain their flowers longer than the normal single-flowered ones." In the case of the Cyclamen the "crest" tendency has been much developed, and no doubt this is just as possible with the Begonia.

FIG. 61.—A "CRESTED" BEGONIA.

the environs are credited with a million kilos. a year, which is about three-fourths of the entire foreign importations of this salad plant. Our gardeners are evidently not the only ones who feel the pinch of "foreign" competition.

PRODUCE OF FRENCH VINEYARDS.—Trustworthy information on this subject is always of interest to consumers in this country—which is so profitable a customer of the French agriculturist. Certainly not the most or the best is made of cider, perry, and Hops in this country; and until proper attention is given to what may be termed our national beverages, French wines of a good class will always command attention. In a recent number of the French *Economist* some interesting particulars are given as to the production and exportation of champagne. Thus we are told that Great Britain is the largest foreign consumer of this wine,

champagne in the States; in this way they could get at the amount to be placed to the credit of the American producer.

THE HEIGHT OF CLOUDS.—A method of determining the heights of clouds, and especially of the ill-defined stratus clouds, by means of the search-light, was suggested by Prof. Cleveland Abbe many years ago. It was proposed to establish a search-light, the beams of which should be vertical: the apparent altitude of the centre of the luminous spot of the cloud was to be observed from a station not far away, and the height was a matter of easy calculation. Prof. C. Abbe returns to the subject in the *Monthly Weather Review* (May), and points out that with the great increase in the power of the modern search-light, further applications have become practicable; thus in harbours on the sea-coast, where one wishes to ascertain the presence and development

HOME CORRESPONDENCE.

APPLE PEASGOOD'S NONSUCH.—In calling at Falkland Park, South Norwood, recently, a bit of information which may be useful to gardeners was gleaned from Mr. A. Wright, viz., that this variety of Apple forms a fruit bud—if in bearing condition—on the terminus bud of the shoots; and if the trees are pruned on the short spur-system, the result is a barren tree. *J. B.*

THE NATIONAL CHRYSANTHEMUM SOCIETY'S DISQUALIFIED EXHIBITS.—The recent disqualification at the Aquarium Show must, in a great measure, be attributed to the ambiguous wording of the schedule. For several years past, various classes for the September Show were stated to be for "blooms of any large flowering varieties," and what is understood to be such have been exhibited with success. This year it reads the same, but a note is appended at the bottom of the amateur classes as follows: "Only the varieties included under the head of early flowering in the society's Jubilee catalogue, '96, can be exhibited in the foregoing classes." This apparently was overlooked or misinterpreted by the various exhibitors, and disqualification was the result. Among the early-flowering varieties given in the catalogue, very few, if any, can be called large-flowering, neither do they all bloom in September. Should not the foot-note distinctly state that the whole of the varieties must be culled from the list as given in the catalogue? And, further, is it advisable to attempt to encourage the cultivation of these small-flowering early varieties, except it be in the natural or bush form? If such stipulation be considered a wise one, then the selection must be compiled with more care than has been displayed in the Jubilee catalogue, for several of the finest and largest-flowering early-blooming varieties are omitted. Two in particular I would mention, viz., Queen of the Earlies and Barbara Forbes. These were sent out as early-flowering varieties in the spring of 1896, and were shown at several of the earlier meetings of the National Chrysanthemum Society in the autumn of 1895. Of the first-named, the late Mr. W. Piercey, no mean authority, repeatedly expressed the opinion that it was by far the finest early white variety in existence; and two seasons ago, Mr. W. H. Lees, who is one of the catalogue committee pronounced it immensely superior to Madame C. Desgranges. Barbara Forbes received the first and only First-class Certificate awarded by the National Chrysanthemum Society throughout last September; yet, strange to relate, neither of these varieties is to be found in the early-flowering list of the National Chrysanthemum Society, and for this reason they were disqualified by the judges (to whom no blame can be attached) at the recent exhibition. That they were known to the committee is proved by the fact that they are to be found in the general selection. It is worthy of remark that several varieties which have repeatedly been exhibited and catalogued by many of the trade are omitted from the catalogue, whilst quite two-thirds of those catalogued have not and never will be grown by English growers. Annie Heard, perhaps the prettiest and most graceful single white flowered Chrysanthemum that we possess, was certificated by the National Chrysanthemum Society and Royal Horticultural Society in 1895; yet it is not to be found in the selected list of singles of the Jubilee catalogue. If not worthy of inclusion, why certificate it, and what value can the members of the catalogue committee themselves place upon the certificates? *W. J. Godfrey.*

PLAQUE OF WASPS.—I do not know if wasps are very numerous this season generally, but this neighbourhood is quite overrun with them. To-day I started five men in search of nests, and within the space of two hours they found no less than nineteen, all within a quarter of a mile of our fruit-garden. To-day I was examining a fruit of *Beurré d'Amanlis* Pear, and I found no less than twelve wasps inside of it. What can one do to protect his fruit under these circumstances? The insects attack the fruits long before they are ripe. *John Butler, Normanton Park Gardens, Stamford.*

LARGE ONIONS.—For some two or three years the Hackwood-raised Onions, chiefly Ailsa Craig, have been the best that have been shown anywhere in the Kingdom, taking all the leading prizes. What will be the entire result of the present year's crop here has yet to be seen; but there are in the garden-sheds hundreds of superb bulbs, ranging from 2 lb. to 3 lb. each, perfect in form, and as solid as a cannon-ball. It is interesting to find that these grand bulbs are

produced each year from the same ground, which is each season deeply trenched, the bottom being brought to the top every time, so that the soil is all of the same quality, and the ample feeding and great depth allow the roots to go deep, and they will do so. Allied to sowing seed under glass in the mid-winter, and putting out the young plants when strong and sturdy in April, these are the chief elements in this method of Onion production. Even if these fine bulbs had no exhibition value, and that is considerable, they constitute first-class seed stock; indeed, it is well known now, that even ordinary outdoor spring-sown seed, if from such fine bulbs, produce by far the finest stocks. I have been able to test that point, this season, on comparatively poor ground at Surbiton, having grown from an ordinary spring sowing of Main Crop, Ailsa Craig, Crimson Globe, Wroxton, and others, far finer bulbs than anyone on the 150 allotments had, with better soil than mine. This seed was saved from very fine bulbs given me in 1895, and grown for that purpose last year. The big bulbs are also valuable for baking or stewing, constituting a mild flavoured yet delectable dish. *A. D.*

LADY HUTT GRAPES.—Last year Mr. Bowerman fruited the black Appley Towers Grape finely at Hackwood Park, but it is not so good this year; and he thinks it is a variety that does best on young rods, and therefore should be grown on the long-rod system in preference to hard-spurred rods. It would be interesting to learn other gardeners' impressions. Lady Hutt, growing in the same house, is this season better than last year. The bunches are fine and massive, and the berries large. Even when fully ripe, there is in them a greenish hue that gives to the variety a distinct appearance. Judging by what is seen of the variety here, Lady Hutt should make a first-rate, late, white Grape, either for exhibition, or for the dessert. The border at Hackwood is outside, and that fact has to be taken into consideration. *A. D.*

THE SPINELESS GOOSEBERRY.—We have a bush of each of the varieties of the so-called Spineless Gooseberry, and for a spineless kind they are wonderfully prickly; they grow very slowly, have had no fruit for two years, and are apparently undesirable additions to our fruit bushes. We will try them for one more year, and if there is no improvement to the rubbish heap they will have to go. *Thos. Fletcher, Grappenhall, Cheshire.*

LARGE PEACHES.—A Peach-tree in an unheated fruit-house at Blithwaite Castle Gardens, Carlisle, has this year borne some exceptionally big fruit, and not having myself seen any of such a size, it may be of interest to record the fact. The tree is of the Barrington variety, and was planted in the beginning of the year 1893. In 1894 it produced three, in 1895 forty, and in 1896 about 140 Peaches of an average size, none of which was over 10 oz. This year it has not matured so many fruit—about forty ordinarily-sized ones, and eighteen large ones—these latter varying in weight from 10 oz. to 14½ oz., well-shaped, nicely-coloured and of good quality. They are borne on a particular branch of the tree which produced very few fruit the preceding year, and this may partly account for the size attained this year, although the limb is on the more shaded side of the tree. *J. Parkin, Blithwaite, Carlisle.*

THE SOUTHERN COUNTIES CARNATION SOCIETY.—Nothing that has been said by your correspondents suffices to remove from my mind the impression that the proposed establishment of a Southern Counties Carnation Society is a move entirely in the interests of Mr. William Garton, Jun. It is true the word "gratis" is written on the side of the circular, but it is not printed, and has evidently been added as an after-thought. The original passage runs:—"Mr. William Garton, Jun., is willing to supply each new amateur member with twelve good and well-rooted plants of different varieties, and also proposes to set aside, out of his large stock every season, a certain number of plants to be distributed among this class of competitors." I presume this was thought to be a little too much of a tout for business, and so the word "gratis" was added by the pen, after that of supply in the first line, and it is now in the form of a bribe to persons to become members. It will be observed that it does not necessarily follow that the term "gratis" applies to the last half of the passage. It therefore appears that in order to induce persons to become members of the Southern Counties Carnation Society, and also obtain possible purchasers of plants from Mr.

William Garton, Jun., a bribe in the way of a gift of plants is necessary. To this I strongly object, as subversive of all the best traditions of floriculture. Almost every so-called amateur, who grows and exhibits Carnations in the present day is a trader, and many of them publish a list of varieties they wish to dispose of. I have no doubt that what is termed in the printed circular the leading professional growers—that is, the legitimate traders—will note this, and hold themselves severely aloof from the Society, or any association with such questionable floral philanthropy. "A. D." appears to find himself in a tight place, and is driven to extremities to find a justification for his hasty and ill-advised advocacy of Mr. Garton's scheme. *An Old Florist.*

PHYSALIS FRANCHETI.—This is an acquisition to our hardy plants. I obtained seed of good vegetative power in 1896, which gave me abundance of plants, whereas that of 1895 was generally bad. The large orange-coloured calices, many of them 9 inches in circumference, have, when cut, a brilliant effect in winter and autumnal decorations of all kinds. The plant is of easy cultivation in good garden-soil, the calices colouring well if the plants are grown in a sunny spot. *N. F. P.*

FRUIT FROM THE CAPE.—Seeing the quotation from the *African Critic* in your last issue, about the apathy exhibited by some of the fruit-growers at the Cape, perhaps the following lines concerning one of the first to attempt teaching them better things may be interesting:—A young gardener named Hutt was with me at Clumber some twenty years ago. He soon afterwards went to the Cape, and is now superintendent at the office of the Board of Trustees of the Maitland Road Cemetery. Returning home some time since for two months' holiday, he visited me at Ruxley Lodge, when we talked of old matters and of new methods. The following remarks were on the Peach as cultivated in the gardens at Clumber. He observed on going to the Cape that the ground for Peach-trees was well moistened during the rainy season, and this he thought agreed with the practice common at Clumber of affording heavy drenchings to the Peach borders during winter at a time when the roots are considered by many to be at rest. I take no credit to myself in the matter of watering fruit borders, for in my apprentice days at Erskine House Gardens, under Mr. Sheila, our orders were to thoroughly water one yard at a time, before watering another yard, and so on to the end of the house, and, if considered necessary, do it all over again. Bud-dropping was not known at Erskine. Mr. Hutt, seeing how luxuriant the Peach tree grew as standards, and how they were smothered with small fruits, which were not thinned, and that when ripe they were roughly gathered into baskets for the Cape market, advised the growers to thin the fruits upon a few of the trees in their orchards, and taught them to prepare them for market at the Covent Garden. The result was a financial success to the growers, as the larger fruits fetched three times the price obtained for the inferior ones in their own market. Mr. Hutt's next move was to try and make England a new market for the Cape. His father being a market-gardener, he had some experience in packing fruits for Covent Garden Market. The growers were somewhat diffident in the matter, but after some persuasion he assisted them to pack three boxes of their best fruits as he had seen them packed at Clumber. One box was sent to Covent Garden, one box to the director of the Castle line of steamers, and one to some other representative person. Hence the beginning of the exportation of Peaches from the Cape. *J. Miller, Ruxley Lodge Gardens, Esher.*

TROPICAL FRUITS.—In last week's Home Correspondence in the *Gardeners' Chronicle* there is an interesting statement on this subject. It is so difficult to judge rightly by one's individual feelings or senses, for there are no two persons who see alike, smell alike, taste alike, hear alike, or feel alike. It is quite true that "judging from the samples of tropical fruit that come to this country," one can have no idea whatever of what really good tropical fruits are like. I once bought an Avocado Pear at one of the London shops for either two or three shillings, and I am sure I never tasted anything nastier! But it is quite a mistake to fancy that those things sold in the London shops are anything like the fruit one gets in tropical countries. My experience is mainly that of the fruits of India, and I declare that there is no finer fruit on earth than a good, ripe Mango. Of this delicious fruit

there are over a hundred varieties. At one time I was studying the Mango fruits, and native gentlemen who possessed Mango orchards used to send me samples of their choice and rare varieties; so I had an opportunity of tasting many a fine thing. There are Mangos almost as large as an ostrich-egg; others as small as a Plum. The best are those of the "Bombay section," of medium size, and, when ripe, of the consistence of butter in winter, and can be eaten with a spoon. It has been always a wonder to me that these fine varieties are never sent to London, for, like the Pear, the Mango admits of being ripened off the tree, better than on it. Those I tasted in London were of a most inferior kind, from Madeira or the West Indies, and would not be looked at in India. Some that I had studied, had the flavour of Nectarines, others of fresh good Figs, but most have a "sui generis" flavour that is not to be met with in either Orange, Grape, Peach, or anything else. Then I have much wondered why the red Banana (plantain) of Bombay has never, seemingly, been introduced into this country. There is nothing like it in all the range of Banana flavours. It is large and astonishingly good. The stumps or roots would travel any distance and vegetate. It is a tall plant with a red stem. Then again, the thin-skinned Pommello of Bombay, with a beef-red pulp, is a fine fruit of the Orange tribe. The Indian Custard Apple (*Anona squamosa*), when just ripe, cannot be compared to any other fruit; and it is distinct, and delicious. You cannot compare one fruit-flavour with another fruit flavour, any more than you can compare a horse with a camel, or Rhubarb with Celery; and it seems an absurdity to state that because we have Oranges, Grapes, Peaches, &c., we are not to have Mangos, Custard Apples, red Bananas, &c. Fruit-growing under glass is increasing in this country, and therefore I see no good reason why tropical fruit-trees should not be added to the long list of British fruits. They are distinct. One would hardly say that, because we have the Lily of the Valley, we do not need the *Lilium auratum*. With regard to Prickly Pears, there are to be had in Malta three of the finest things in the way of fruit, viz, the white-fruited, the yellow-fruited, and the red-fruited Prickly Pears (*Opuntia Ficus indica*). When fully ripe their flavour is unique, and cannot be compared with any flavour of English or other fruits, and it is simply delicious. The choice varieties are to be found only in private gardens. *E. Bonavia, M.D.; Sept. 13, 1897.*

THE LOQUAT.—In reply to Mr. Clarke's letter in your issue for September 4, we have a plant here which is quite thirty years old, and grows in a conservatory kept at a temperature of about 50° during the winter. The plant blooms about November, and produces fruit annually, but not a heavy crop, possibly because it blooms during sunless weather. The fruit ripens during spring, and resembles a small smooth orange, about 1½ inch in diameter. In flavour it is rather insipid, and not by any means desirable as a desert fruit. *George Harris, The Castle Gardens, Alawick.*

THE CARROT IN INDIA.

SIR GEORGE BIRDWOOD, to whose forethought India owes many of the good things of other climes, gives a very interesting account of the history of the Carrot in that great country, from which we take the following notes:—

"The Carrot would appear to have been continuously known in India from at least the time of the Great Akbar, the contemporary of Queen Elizabeth, and it has long been in cultivation as a garden crop throughout India; while in the Bombay Presidency it is not only cultivated by Europeans as a garden crop from imported English seed, but also widely, if irregularly, as a field crop by the native ryots, who use acclimatized seed,* originally obtained, if I remember

* The acclimatized seed is obtained in Western India by digging up the Carrot when its root has attained about one-third its full size, and cutting off both the root and the leaves, or "tops" (which are eaten as a *baaji*, or, as we say, "greens") of the plant within a couple of inches of "the crown of the root." The portion of the root remaining attached to the stalk is then deeply incised cross-ways and dipped in a strong compost of the mixed dung of the pig and buffalo and virgin-earth, the lateritious earth of the Deccan being preferred with a little *assafoetida* added, and as much liquid-manure as will reduce the mass to an adhesive paste. The roots are then, with the usual religious ceremonial, planted out and watered, and in due course produce strong flowering stems and large umbels of characteristically aromatic fruit.

rightly, from the Cape of Good Hope. It is sown in the 17th and 18th lunar asterisms during the months of November and December, and is reaped in the 22nd and 23rd during the months of January and February, yielding, usually, an abounding crop.

The plant is indeed found growing spontaneously in Cashmere, and on the Western Himalayas at elevations of from 3,000 to 9,000 feet above the sea level, and is probably indigenous to the region; Central Asia, from the Himalayas to the confines of Russia, appearing indeed to be the aboriginal habitat of almost all the immemorially familiar pot-herbs of the old world.

But as the plant is known throughout central and south-western Asia by its modified Greek name, *setyfin*, as well as by the name of *gacar*, one of the many eastern variants of its Sanskrit name *Garjara* (literally "grass," i.e., vegetation), it may possibly have been introduced into Cashmere by the Macedonian Greeks. The fact of the plant being found growing wild in the Western Himalayas, and of flourishing in India wherever it is cultivated, gives the strongest support to the opinion of Sir Edward Buck, that the cultivation of the Carrot as a field crop from improved European seed is capable of universal extension in India.

All the factors of success in Carrot cultivation are found over the greater part of India. The natural soil is nearly everywhere light and loamy, and easily dug, and penetrated by tap-roots to a great depth, and self-draining; and the conditions of climate permit of the seed being sown continuously from August 15 or 30 to November 15 or 30 (in Bombay to December 15), and of the roots being continuously cropped from end of November to the beginning of June. There is also, in normal seasons, sufficient rain for the seed times, while, as the plant is usually raised in India as a garden crop, or by *petite-culture*, artificial irrigation for it is always at hand. In view, however, of the gratifying results of the encouragement given in the last century by the Society of Arts to Carrot-growing in the United Kingdom, it is deserving of consideration whether the Government of India might not, with even greater public advantage, offer small prizes all over that country for the extended or improved cultivation of Carrots, as, indeed, of other quickly-maturing root crops; and this could be easily done either directly or through the intervention of the various provincial agricultural and horticultural societies with which the Indian Government is more or less responsively associated."

THE CREEPING SPECIES OF FICUS.

SEVERAL species and varieties of *Ficus* with the habit of that popularly known as *F. repens*, have recently been brought into cultivation, and are likely to find favour as garden plants. The last is *F. radicans* variegata, introduced by Mr. W. Bull and exhibited by him at the Temple show in May last, and again recently at a meeting of the Royal Horticultural Society, when it was awarded a First-class Certificate. A figure of this plant was published in the *Gardeners' Chronicle* last week.

The names of these plants are, however, somewhat puzzling. Thus *F. radicans* appears to be a garden name for a plant of which a flowerless specimen collected by Sir Joseph Hooker in Chittagong, and still unnamed, is in the Kew Herbarium. The name *radicans* had been given by Roxburgh to the species known to botanists as *F. rostrata*, which is quite distinct from *F. radicans* of gardens. This name may therefore be retained for the plant under notice, at any rate until it can be determined botanically. Some cultivators confuse this plant with *F. repens*, but the two are quite distinct in habit and leaf-characters. They may be distinguished as follows:—

F. RADICANS, Hort.—Stems creeping, smooth, wiry, green when young, dark brown when old, rooting freely, and bearing at intervals of about an inch alternate leaves with whitish stipules; petiole half an inch long; blade lanceolate, cordate at the base, 3 inches by 1 inch, bright green. An evergreen useful for covering walls, pillars, &c., in warm

houses. The variety variegata has leaves prettily marbled, and margined with milk-white.

F. STIPULATA, Thunberg.—This is the plant popularly known as *F. repens*, a smaller-leaved form of it being known as *F. minima*. It has ovate, obliquely-cordate leaves, from ½ to 1 inch long in its creeping or barren stage, and much larger lanceolate-cordate leaves in its tree or flowering stage. It is nearly hardy in England—quite hardy, in fact, in the south if planted against a south wall; one of the most useful plants for indoor gardening, filling as important a place there as the two species of *Ampelopsis* do out-of-doors. It is a native of Japan and China, where it is commonly cultivated. It has been in cultivation in England since 1771. In his recently-published monograph of the Indo-Malayan species of *Ficus*, Dr. King refers *F. stipulata* to *F. pumila* of Linnaeus, but for garden purposes the former name may properly be retained for the creeping or barren form of the plant.

F. FALCATA.—This is a species of recent introduction, which we owe to Messrs. H. Low & Co. It is of similar habit to *F. stipulata*, and is likely to prove as useful for clothing damp walls, &c., in warm houses. In the nursery of Messrs. F. Sander & Co. at St. Albans, there is a beautiful example of it on a wall in a stove, where it has grown very quickly in a somewhat shaded, moist situation. It is also planted as a wall-covering in the tropical fernery at Kew. The stems creep and root and branch quite as freely as *F. stipulata*, and the leaves are an inch long, obliquely oblong, with a slight curve, whence the name *falcata*; they are of a dark lustrous green colour, and decidedly attractive. According to Dr. King, this is a form of *F. punctata* of Thunberg, and is a native of the Malayan Peninsula and Archipelago, where it is not uncommon on trees and rocks. He describes it as "a very remarkable and beautiful species, varying much in fruit, and in the shape of the leaves, even in the same plant, the leaves on its small branchlets from the lower part of the main stem being often much smaller than those from branchlets near the apex, and occasionally different in form."

F. BARBATA.—This species is sometimes met with in large tropical houses, where it covers Palm-stems, pillars, &c., with long trailing shoots, bearing leathery ovate-oblong hairy leaves, about 6 inches long. It has long been an inmate of the Palm-house at Kew. It is a native of the Malayan Peninsula and Archipelago. To recapitulate, we have now the following creeping Figs in cultivation:—

F. barbata, Wall.
F. falcata, Thunb. (a form of *F. punctata*, Thunb.)
F. radicans, Hort. (not of Roxburgh).
var. *variegata*, Bull.
F. stipulata, Thunb. (the barren form of *F. pumila*, Linn.)

syn. *F. repens*, Hort.
var. *minima*, Hort.
I am indebted to Mr. W. B. Hemsley for assistance in identifying these plants. W. W.

COLONIAL NOTES.

THE BAHAMAS.

THE report of the Colonial Secretary of the Bahamas on the condition of the islands for the past year is, on the whole, satisfactory. The value of the imports last year was £194,774, and of the exports £139,000, the figures in both cases showing material increases over the corresponding returns for the previous year. The increase in imports took place in foodstuffs, cigars, coffee, corn, hay, wood, salt, meat, and bicycles; in exports, *Grasses*, *Tomatoes*, salt, sponges, turtle-shell, and logwood were all in larger quantities, while the production of *Sisal-fibre* was nearly doubled. After referring in detail to the various plantations of *Sisal* in the islands, the Colonial Secretary says:—"The prospects of this new industry are now becoming more defined, and, although it has absolutely failed to fulfil the anticipations once formed of it, there seems to be less reason to fear that it will die out altogether, and some reason to hope that it may in time become a small but well-established industry, returning fair profits to those engaged in it, and giving a much-needed variety to the colonial products, which at present are all included in the sponge and fruit trades."

SOCIETIES.

ROYAL CALEDONIAN HORTICULTURAL.

(Concluded from p. 191.)

THE TRADE EXHIBITS.—Without the substantial support afforded by the trade generally, the opening ceremony, and the show itself, would have been shorn of much of its more important features.

Messrs. JOHN DOWNIE & SONS, Edinburgh, furnished a great number of plants, the space occupied by their exhibits being 300 square feet. Messrs. DORRIS & SON, of Rothesay and Orplington, furnished a table of cut flowers measuring 60 feet in length, and 5 feet in width. Messrs. DICKSON & SONS, of Edinburgh, showed extensively; Messrs. FORBES & SONS, Hawick, exhibited a Jubilee table of cut flowers, fine collections of Hollyhocks, Pentstemons, Carnations, and other herbaceous plants. Messrs. FORBES & SONS made a most interesting exhibition of shrubby Phloxes, illustrating their evolution during the last century, from a poor needy-looking variety to the fine exhibits and high-coloured varieties of to-day. This firm were 1st for eleven spikes of Hollyhocks; and Mr. C. IRVINE, Jedburgh, was 2nd. Why eleven? Do the schedule framers believe that good luck is found in odd numbers?

In the gardeners' and amateurs' classes of Hollyhocks, the number of spikes of Hollyhocks required was five. Mr. OLIVER, Morpeth, an old Hollyhock fancier, being 1st in this class; Mr. BENNET, Tweedmouth, 2nd; and Mr. RICHARDSON, Peebles, 3rd.

There was also a class for six blooms of Hollyhocks, in which Mr. OLIVER was also 1st, and Mr. BENNET, 2nd.

In the class for twelve blooms, Mr. OLIVER was 1st; Mr. BENNET, 2nd; and Mr. G. HOOD, Edinburgh, 3rd. These Hollyhock exhibits were, as a whole, the finest and most promising I have seen for many years.

Messrs. DORRIS's stand, which covered 250 square feet, was backed with Palms, Ferns, and tall herbaceous plants of the choicest species and varieties, and furnished in front with show, fancy, Pompons, Cactus, and single-flowered Dahlias, some 200 varieties in all arranged in a striking manner, the whole being edged with flowers of their fine strain of French Marigold.

Messrs. R. B. LAIRD & SONS, Frederick Street, Edinburgh, had a large exhibit of various subjects arranged for effect, the one helping the other. Cut flowers of herbaceous plants were in great variety, forming an important feature of the group.

Messrs. THOS. METHVEN & SONS, 15, Princes Street, Edinburgh, had a table of Lilliums, double-flowered tuberous Begonias, Crotons, Caladiums, Crozy's Cannas in variety, Pancratiums, Palms, and Ferns, arranged as a ground-work to the group, which was artistically arranged. The whole was interspersed and brightened with Lilies in fresh condition, including *L. auratum*, *L. a. rubro-vittatum*, *L. a. platyphyllum*, and *L. lancifolium*.

Messrs. DICKSON & Co., 1, Waterloo Place, Edinburgh, had a large and bold table at the east end of the market. Along the centre of their tables were very good young pot-Vines, as well as fruiting Vines and Peaches in pots, arranged in place of the usual Palms. The fruiting Vines consisted of Lady Hutt and Apple Towers. Violas, new varieties of Picotees, and Carnations, the latter including Dowager Duchess of Athole (a white perpetual-flowering variety), Duchess of Fife (shell-pink), and others were shown. Hardy shrubs were represented by *Colutea orientalis*, *Prunus Pissardi*, *Hypericum Moserianum* var. *tricolor*, *Spirea Bumalda*, *Abies pungens* glauca *Kosteri*, and the Japanese Wineberry.

Mr. HENRY ECKFORD, Wem, Shropshire, staged a collection of Sweet Peas in many of the more interesting and newer varieties, which always create interest.

Messrs. DICKSON & Sons, 32, Hanover Street, Edinburgh, had a group of the more interesting and useful Conifers, arranged round the sides of the band stand. Some of the more showy were the Golden varieties of *Cupressus juniperus*, *Thuja* and *Retinospora*, and *Abies Parryana* glauca.

Messrs. JAMES GRIEVE & SONS, Redbraes Nursery, Edinburgh, had a table of choice Palms, Aspidistras, Dracenas, bronze and tricolor Pelargoniums, and New Zealand shrubby Veronicas in great variety for pot work. All these were brightened with such flowering plants as tuberous-rooted Begonias, single and double flowered; also choice Sweet Peas, Carnations, Violas, and choice herbaceous flowers. They also had a beautiful anchor of flowers.

Messrs. KERR BROS., Dumfries, exhibited a collection of new varieties of show, fancy, and Cactus Dahlias, and herbaceous plants. Mr. JAMES ROWATT, Glasgow, by Strathaven, staged Pentstemons, Phloxes, and China Asters in variety. Mr. JOHN PHILLIPS, Granton Road Nurseries, Edinburgh, had a table of *Araucaria excelsa* in plants of various sizes, interspersed and brightened with Lilies and Carnations, Ferns, Selaginellas, and other plants. Messrs. LAING & MATHER, Kelso-on-Tweed, had a table of the new hybrid continuous-flowering Chrysanthemum Princess May. They had also a fine lot of their popular Carnations, including the new self, Viscountess Melville. The Chrysanthemum is quite hardy, and has been flowering outside and inside for eighteen months.

Mr. A. FINDLAY, Markinch, Fifeshire, showed a table of new varieties of Potatoes, including Klondyke, said to be the earliest variety in cultivation. They may be dug eight weeks from the time of planting.

Messrs. SCARLETT BROS., Musselburgh, had a fine table of vegetables and herbs, including Vegetable Marrows, Cabbages, Cauliflowers, Scarlet Runners, &c.

Mr. MICHAEL CUTHERBERTSON, Rothesay, N.B., had a table of alpine plants in pots, including about seventy species and varieties of Saxifrages; also a collection of Sedums and Sempervivums. He also had cut flowers of herbaceous plants, conspicuous amongst which was a collection of Montbretias, new Phloxes, Lemoine's hardy Gladioli, and the new Rudbeckia Golden Glow.

Mr. HUGH HANAN, 9, Bank Street, Edinburgh, had a fine collection of Sweet Peas in seventy varieties. On his table were long flowering stems of *Tropaeolum speciosum*, and growths of *Smilax*.

Mr. A. LISTER, florist, Rothesay, N.B., had a collection of Sweet Peas, Carnations, Pentstemons, Dahlias, herbaceous plants, and Pansies, elevated to a high ridge along the centre of the table, making a very pleasing and effective exhibit. A new Dahlia, named Jeannie Alister, is a single Cactus variety of a new shade; and Lister is a purple variety with pointed petals.

Messrs. FORD & Co., glass manufacturers to the Queen, 39, Princes Street, Edinburgh, had an exhibit of the latest table decorations, rustic glass, tastefully arranged en suite, in tubes, flower-stands, and bowl centres.

Hydrangea paniculata, *Gladioli*, *Lilium Harrisii*, and other flowering plants lightened up the Palms, Ferns, and *Araucaria excelsa*, all of which were arranged in tiers that were shown by Messrs. M. TODD & Co.

THE OPENING.

The ceremony of formally opening the Show took place at 1 o'clock on the first day, when the Marquis of LOTHIAN, President of the Society, delivered the inaugural speech, in presence of a considerable gathering of spectators, including the Earl of Morny, Lord Provost, Sir Andrew McDonald and Lady McDonald, General Hope, Sir John Cowan, Professor Annandale, Professor Bayley Balfour, Members of the Town Council, and other gentlemen.

DERBY.

SEPTEMBER 8, 9.—The thirty-sixth annual exhibition was held in conjunction with the agricultural show on the above dates, and was a great advance on any that have preceded it, due probably to some important alterations that have been made in the schedule and in the management of the show, which induced more cultivators to compete in many of the classes.

GROUPS.—The principal features were the fine groups of plants filling the central portion in a circular tent, the eight competitors following the improved style of arranging their plants, and there was nothing to mar the uniformity of the whole. All the groups were good, and any one of them would have been 1st at an ordinary show, thus giving the judges no light task to make their awards. Eventually Mr. Ward, gr. to T. H. OAKES, Esq., Riddings House, Alfreton, was placed 1st for good culture as shown by the plants, and for graceful arrangement of them. His Crotons were very fine examples as regards the colour and size of the foliage, and they were well contrasted with *Ixoras*, *Lily of the Valley*, a variety of *Orchids*, *Cocos*, and other Palms, the whole of the pots being hidden with moss. Mr. MEE, of Nottingham, was 2nd, with a very prettily-arranged group, containing good Crotons, Palms, *Acalyphas*, some good potulds of *Nertera depressa*, and good plants of *Nepenthes* prettily arranged over a small pool of water, the whole forming a very pleasing combination. Mr. CYPHER, of Cheltenham, was 3rd; his group was specially noticeable for the fine lot of *Dendrobiums* arranged on branches of virgin cork, also for several fine pieces of *Odontoglossum*, &c. This group contained the best flowers, but it lost points in arrangement.

Messrs. VEITCH & SONS staged a splendid group of plants, not for competition, containing many of the fine-foliage Caladiums for which the firm is noted; also some of their improved varieties of greenhouse Rhododendrons, a beautiful specimen of *Dayallia Veitchii*, and some fine specimens of *Nepenthes*, the whole being tastefully arranged with various Ferns, *Bouvardias*, hybrid *Streptocarpus*, and the fine winter-flowering *Begonia Gloire de Lorraine*. For this group they were awarded a Gold Medal.

DECORATIVE DESSERT TABLE.—Mr. GOODACRE, of Elvaston Hall Gardens, won the 1st prize against three other exhibitors, with a nice collection, containing Queen and smooth Cayenne Pine apples, excellent Muscat of Alexandria and Gros Maroc Grapes, Hero of Lockinge Melon, two grand dishes of Peaches (Sea Eagle and Golden Eagle), and a dish of Gasconne's Seedling Apple, &c. The floral decorations of this table consisted of *Orchids*, *Asparagus plumosus*, *Smilax*, &c.; 2nd, Mr. WARD, gr., Riddings House, who staged a very fine Queen Pine, dishes of good Grapes, Peas, &c., set off by a graceful arrangement of flowers and foliage.

FRUIT.—In the fruit classes some very fine bunches of Barbarossa Grape were staged by Mr. McCulloch, who took the 1st prize; the 2nd going to Mr. McVinish, who staged medium bunches of Madresfield Court. In the class for three bunches of Muscat of Alexandria, Mr. GOODACRE was well to the front with capital examples; 2nd, Mr. McVinish, Lockington Hall.

CUT FLOWERS.—Mr. JENKINSON, Newcastle, Staffordshire, won the premier position with various *Orchids*, *Roses*, *Carnations*, *Cactus Dahlias*, *Lilies*, *Gloriosa superba*, and other flowers, set out tastefully against a dark background, and

relieved with shoots of *Asparagus plumosus*, Fe 2nd, Mr. CYPHER, who staged *Orchids*, *Asparagus*, &c.

MISCELLANEOUS.—Silver Medals were awarded GOODACRE for a fine group of *Begonias* and *Ferns*; FINCH for a similar exhibit; to Mr. WHITE, Worcester collection of herbaceous flowers, *Dahlias*, &c., which *Colchicum speciosum caucasicum* was especially to Mr. DEVERILL, Banbury, for a fine collection of his flowers, *Dahlias*, &c.

Cactus and other Dahlias were excellently staged by Messrs. CHEAL, of Crawley (Bronze Medal).

VEGETABLES were remarkably good. The chief prize taken by Mr. McVinish, gr., Lockington Hall; Mr. gr., Bretby Park; and Mr. WOODGATE, gr., Rolleston. The amateurs' and cottagers' classes contained some fine specimens, the competition in some instances very keen.

WELLINGBOROUGH AND MIDLAND COUNTIES DAHLIA.

SEPTEMBER 11.—This was the second exhibition, and such a remarkable advance upon that of last year's permanence is assured. The open classes attracted leading growers—trade and amateur—from the south if the majority of the leading prizes were carried off by them yet exhibited blooms of such fine character, valuable object lessons, which will be learned by growers. The takings at the doors denoted an interest in the exhibition, and it is probable it will be two days' show in the future.

There were nine entries in the class for twenty-four ties, and equal 1st prizes were awarded to Messrs. J. T. FARMAN, Farnham, Surrey; and Mr. G. HUMPHRIES, Chesham. A few of the best blooms in these two stands mentioned:—Perfection, J. B. Service, John Hickling Gladstone, Shottesham Hero, Glow-worm, Arthur R. Duke of Fife, W. H. Williams, Frank Pearce, Lordford, Mrs. Langtry, William Rawlings, Miss Florence Tranter, James Stephens, Henry Walton, a Fox; Mr. J. T. WEST, Cornwallis, Brentwood, Wash. Mr. J. R. TRANTER, Henley-on-Thames, 3rd, with ten stands. With twelve varieties Mr. MORTIMER was 1st.

The practice of exhibiting Cactus blooms on show as in the case of the show varieties, is followed at Wellingborough. Mr. MORTIMER, and also Mr. WEST, set up fine stands of twenty-four distinct blooms each, an advantage rested with Mr. MORTIMER, closely pressed WEST. Such varieties as J. E. Frewer, Princess Beatrice, Gloriosa, Wm. Stradwick, Starfish, Mrs. L. Se Matchless, delicate, Cycle, Mrs. G. Sloane, Cassar, Ruby, Island Queen, Ethel, and Octopus were seen as best.

Messrs. MORTIMER and WEST were also 1st and 2nd twelve varieties.

Mr. WILLIAM BAXTER, florist, Woking, had the best varieties, three blooms in a bunch, fine in quality, admirably set up; and Mr. J. WRIGHT, nurseryman, Woking, had the best twelve bunches of Pompons, a little in size, but nicely set up on wire frames.

There were several classes for amateurs, open to all. Mr. R. BURGIN, St. Neots, taking the leading prize show and fancy Dahlias; and Mr. H. A. NEESE, V for Cactus and Pompons, staging in admirable style. Certificates of Merit were awarded to new varieties.

FRUIT.—Some classes were set apart for fruit. Six dishes came from Mr. HAYES, The Gardens, Castle.

The best two bunches of Grapes, well-finished, Hamburg, came from Messrs. CLAYTON & SON, Wellingborough.

Miscellaneous collections of Dahlias were shown by GREEN, Norfolk Nursery, Dereham, and others; and fine Apples were contributed by Messrs. H. and E. nurserymen, Wellingborough.

MANCHESTER AND NORTH ENGLAND ORCHID.

SEPTEMBER 9.—At this season the number of Orchids which flower is comparatively few, but this is made up by the fine quality of those which do flower. The best were present:—G. SHORLAND BALL, Esq., Ashford, chair; and Messrs. S. GRATRIX, E. J. Sidebotham, Dr. Kinson, J. Cypher, W. A. Gent, J. Anderson, Wm. S. A. Warburton, H. Greenwood, R. Johnson, Jas. Back and Wm. Bolton.

S. GRATRIX, Esq., Whalley Range (Mr. R. McLeod, gr. *Cypripedium bellatulum album* (First-class Certificate), clean flower, which gains in whiteness after a day's sun. It is an exquisite variety, and received an Award. The same exhibitor showed *Laelia praestans*, flower with bright segments, and a lip of a bright tint, but with a centre that was blotched with white, was no improvement. It received an Award of Merit.

A. WARBURTON, Esq., Vine House, Haslingden (gr. *Lophouse*), exhibited a fresh, well-grown plant of *Cidium insigne* Laura Kimball, which, although it was awarded in London, was here awarded a First-class Certificate. It was the first of the yellow *C. insigne* that has come to this Committee, and it has improved on acquisition.

although there were experts who had doubts of its maintaining equal rank with *C. insignis* Sandere.

THOMAS STATTER, Esq., Stand Hall, Whitefield (gr., Mr. R. Johnson), exhibited a lot of good Orchids, foremost among them being *Cypripedium* *x* *triumphans*, a variety that is undoubtedly the most brilliant of its class, and it is no disparagement to the others of the class to say that among varieties of the *C. crenatum* superbum it is the best. Its form is possibly not so perfect as one would like, but its brilliancy and the features derived from *C. Salteri*, make it a pretty flower. Th's exhibitor showed *Lælio-Cattleya callistoglossa* (Award of Merit), a fine hybrid with a showy lip, and the other parts of the flower tend to make it a desirable variety. *Lælia elegans* *Cheloniensis* was given an Award of Merit, due probably to the brilliant colouring of the lip, for the flower itself is too small for the present taste in these plants. *Cypripedium* *x* *Memoria Moensii* obtained an Award of Merit—we have seen it much better; also *Cattleya Parthenæ*.

Messrs. H. Low & Co., Clapton, had a magnificent plant of *Lælia elegans* *Cawenbergii*. It is a striking plant, with the flowers in close order on the flower-spikes. The rich purplish-crimson lip, adorned with a peach-like tint, took the eye of the committee, although they stopped short of voting it a First-class Certificate, and it received a Cultural Commendation and an Award of Merit instead. The same firm also presented *Cypripedium* *x* *Alfred Hollington*, which has already been described in these pages. It received an Award of Merit. The same award was meted out to *Cattleya Murrucæ* = *C. Harrisoni* *x* *C. gigas*.

J. LEMANN, Esq., West Bank House, Heaton-Mersey (gr., Mr. Edge), showed *Anguloa eburnea*; it is an old favourite that is now seldom seen. The flowers were developed to perfection, and the plant received an Award of Merit. The same exhibitor had also a fine plant and variety of *Cattleya aurea*, with an extra broad lip, nearly wholly of crimson-purple, with faint threads of gold throughout.

E. J. SIDEBOTHAM, Esq., Erisden (Mr. Shiner, gr.), had the finest *Cattleya speciosissima* yet submitted to the committee (Award of Merit). The segments were full and unusually well-formed. It was described in full in *Gardeners' Chronicle*, 1896, and of the two in flower, called A and B, the best was the A variety, although, in our opinion, it was not so well developed as last season.

Mr. JAS. CYPHER, nurseryman, Cheltenham, was voted an Award of Merit for a novel lemon-coloured *Oncidium Jamesianum* distinct from the type.

Wm. THOMPSON, Esq., Walton Grange, Stone (Mr. Stevens, gr.) showed a group consisting of *Odontoglossum crispum*, comprising self coloured and spotted varieties along with *O. tripudians*, the showy *Masdevallia Veitchiana* of the better type, and several other species, for which the Committee awarded a Silver Medal.

BIRDS USEFUL TO GARDENERS AND FARMERS.

THE KESTREL OR WINDHOVER (*FALCO TINNUNCULUS*).—This beautiful and valuable bird is often wantonly killed either for the sake of shooting at something wild, and the pleasure of seeing it stuffed and set in a glass-case, or because of an exaggerated idea on the part of gamekeepers that it is a systematic destroyer of young partridges and pheasants, grouse, hares, and rabbits.

The wholesale destruction of such birds as the kestrel is frequently the main cause of abnormal and sudden attacks upon crops by animals and insects. In favourable conditions of climate and other circumstances, and in the absence of the checks provided by nature against their undue increase, certain animals multiply exceedingly, and do infinite harm, as was exemplified by the serious injury occasioned to grass-land in parts of Scotland by voles in 1892. Insects also appear more frequently and in larger numbers in these later days, owing in a degree to the destruction of birds, their natural destroyers. As an example, it may be observed that the enormous decrease in the number of swallows on account of their alleged destruction in their winter quarters, has, it is fully believed, been one cause of the increased swarms of aphides which now come upon the Hop plants regularly every season. In their migration from the Plum and Damson trees, and other trees of the *Prunus* tribe, these insects were formerly cleared off by the swallows. Now, swallows are so reduced in numbers that they have little influence upon this and other insect attacks.

The kestrel prefers animals of the mouse tribe to all other forms of food. Yarrell, in his *History of British Birds*, says, "Mice certainly form the principal part of the food of this species." It also feeds on beetles, especially cockchafers and wireworms (the larvae of click-beetles), and frogs. When it cannot

get mice it will occasionally take very young birds, as pheasants, partridges, and grouse, but according to all observers it preys chiefly upon mice and insects; and in the report of the Departmental Committee, appointed by the Board of Agriculture to inquire into a plague of field voles in Scotland in 1892, it is stated that the food of the kestrel is known to consist almost exclusively of mice, grasshoppers, coleopterous insects, and their larvae.

Keepers do not always discriminate between hawk and hawk; and because other hawks, as the sparrow-hawk, for instance, take young game-birds wholesale, it is often erroneously concluded that the kestrel is equally an offender in this respect. In the report referred to above, it is observed, in connection with the question of the kestrel's habits, that it is rare to find people able to distinguish between one kind of hawk and another. Few of the witnesses who gave evidence before the Departmental Committee were able to describe hawks' otherwise than as red, blue, brown, or yellow, and it was often found impossible to make out what species they intended to indicate.

The identification of the kestrel is easy on account of its practice of hovering in the air, without motion, for a long time. Its graceful flight is also different from the rapid dashes of the sparrow-hawk. It is about 15 inches from head to tail, the female being slightly smaller.

Copies of this leaflet can be obtained free of charge and post-free on application to the Secretary, Board of Agriculture, 4, Whitehall Place, London, S.W. Letters of application so addressed need not be stamped.

FLORISTS' FLOWERS.

CHRYSANTHEMUMS.

DURING the present month the plants should receive a good deal of feeding; but this, like everything else, needs a little care. Many good-looking plants get spoiled by indiscriminate and excessive feeding, which ruins them at flowering time, and lets in a gardener, say, at an exhibition, whose plants were at one time rather insignificant-looking. The best sorts of manure are the voidings of animals, such as those of the stall-fed ox, horse, and sheep, changing these from week to week, and affording clean water occasionally, as a change and to sweeten the soil, remembering that the plants may have a surfeit of good things. Another matter to attend to is the getting of the wood well matured, and to do this the plants must stand in the full sunshine the entire growing season, and not be fed too lavishly, or the shoots will be so gross and sappy, that no amount of autumn sunshine will ripen them.

Obituary.

MR. JAMES COCKER.—Many will hear with regret of the death of Mr. J. Cocker, the senior partner in the Aberdeen firm of Messrs. Cocker & Sons, nurserymen, of that town. His death took place at Sunnyside, Aberdeen, in the sixty-fourth year of his age. A brief account of the life of the deceased will appear in these columns shortly.

VARIORUM.

HOW TO DESTROY SCALE, &c.

WE hear of all sorts of remedies for scale, but none is so good as the old one of white-washing the trunk and limbs of, say, a Plum, Pear, Orange, or Fig-tree. If there are many small shoots that require removal, see that this is done before the lime-washing takes place. *Nerium Oleander* is apt to be badly infested with white scale, and a lime-wash applied in the winter will remove these.

Applied to the stem and limbs of orchard-trees, it clears them of moss and lichens, although æsthetic folk may not admire the appearance of the trees so treated, and will contend that less unsightly means might be taken to kill the moss, &c. The chief thing, however, is freeing the trees from the parasitic growths, and maintaining them in good condition. We have seen it stated that lime-washing will destroy mealy-bug, but we have our doubts.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Districts.	TEMPERATURE.					RAINFALL.		BRIGHT SUN.

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W. 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending September 11, is furnished from the Meteorological Office:—

"The weather continued very unsettled and rainy during the earlier days of the week, but subsequently became fine and dry in all parts of the kingdom.

"The temperature was again below the mean, the deficit being as much as 4° or 5° in most parts of the country, and 6° in 'England, N.E.' and 'Scotland, E.' The highest of the maxima were recorded, as a rule, on the 11th, and varied from 69° in the 'Midland Counties,' 'England, S.' and 'Ireland, S.' to 61° in 'Scotland, W.' and 'England, N.W.' The lowest of the minima, which were registered towards the end of the week, ranged from 29° in 'Scotland, E.' 30° in 'Scotland, N. and W.' and 32° in the 'Midland Counties' and 'Ireland, N.' to 40° in 'England, S.' and to 49° in the 'Channel Islands.'

"The rainfall exceeded the mean in 'England, E. S., and S.W.' and the 'Midland Counties,' as well as in 'Ireland, S.' and the 'Channel Islands;' in other districts, however, there was a deficit. The fall in 'England, S.W.' and the 'Channel Islands' was again very heavy.

"The bright sunshine exceeded the normal in Ireland, Scotland, and 'England, N.W.,' but was deficient in most other parts of the kingdom. The percentage of the possible duration ranged from 50 in 'Ireland, N.,' 49 in 'Scotland, W., and 46 in 'Scotland, N.' to 32 in 'England, S.' and 23 in 'England, N.E.'"

MARKETS.

COVENT GARDEN, SEPTEMBER 16.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly very Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

FRUIT.—AVERAGE WHOLESALE PRICES.

s. d. s. d.	s. d. s. d.
Apples, Dessert, in variety, p. bush. 8 0-10 0	Melons, each ... 0 9-1 6
— Culinary, in variety, per bush. 3 6-5 0	Mulberries, per gal. 1 6 —
Blackberries, peck 2 6-3 0	Nectarines, selectd. fruit, per doz. 6 0-8 0
Damsons, 4-bushel 7 6 —	— Medium, p. doz. 3 0-4 0
Figs, per doz. ... 1 0-2 0	— Seconds, p. doz. 1 6-2 0

POTATOS.

With moderate supplies of Potatoes, prices rule as follows:—Hebrons and Snowdrops, 75s. to 90s.; Giants, 70s. to 80s.; Blacklands, 60s. to 65s.—John Bath, 32 and 34, Wellington Street, Covent Garden, W.C.

SEEDS.

LONDON: Sept. 15.—Messrs. John Shaw & Sons, Seed Merchants, of Great Malte Pond, Borough, London, S.E., write that retail sowing orders for Trifolium are still coming to hand; very little seed will remain over unsold. The sale for Mustard and Rape seed continues slow. Winter Tares of excellent quality are now obtainable for very little money.

The Rye-market is steady. Peas and Haricots meet an improved demand at values favouring holders. The inquiry for Canary and Hempseed is small. There is no change in Linseed. The new English Longpods show good quality. Alsike and Trefoil attract some speculative attention.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qr.), for the week ending September 11, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1896.	1897.	Difference.
	s. d.	s. d.	s. d.
Wheat	23 9	33 1	+ 9 4
Barley	23 4	27 4	+ 4 0
Oats	14 1	17 3	+ 3 2

(Markets carried over to p. ix.)

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

WESTWOOD.—There is an apparatus heated by an oil-lamp, and used for purposes of propagation of plants. Can any of the readers of the *Gardeners' Chronicle* indicate the name of the firm which supplies such apparatus?

BOOKS: *F. P., Cambs.* We imagine that you require a book treating of the chemistry of soils—not gardening. You should obtain Dr. W. Frearm's *Soils and their Properties*—one of Bell's Agricultural Series—price 2s. 6d. (Bell & Sons, York Street, Covent Garden, W.C.)

CHRYSANTHEMUM LEAVES DISEASED. *R. E. T.* The green resinous colouring matter has entirely disappeared, but how? And in lack of more precise information as regards your method of culture, manures used, &c., and more abundant material, we are unable to advise. That the plants affected cannot produce good flowers is certain.

CORRECTION, GLASGOW SHOW.—The exhibit of Pentstemons and Hollyhocks erroneously credited by our reporter to Messrs. Dobbie & Co. were exhibited by Mr. C. Irvine, of Jedburgh.

GRAPES: *C. S.* The berries sent are attacked by the minute fungus, *Glaeosporium laticolor*. Cut out and burn every affected berry, for there is no known cure.

HIBISCUS: *W. L. H.* Some greenhouse and warm-house species, as *H. Trionum*, may be increased from seed, and all of them may be struck in a warm frame over bottom-heat, or in a case in the propagating-house in the spring, the cuttings being taken from plants that have been forced into growth. *H. syriacus* (*Althea frutex*), a hardy shrub, grows well from seed, which ripens in this country in warm seasons. Layering of the best varieties of *H. syriacus* is advisable, and cuttings may be struck, cool, under bell-glasses, but it requires much patience on the part of the propagator.

NAMES OF FRUITS: *J. C.* The slight boxes containing Plums were partially smashed, and the fruit much damaged.—*A. B. W.* Fondante d'Automne.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*Anxious.* *Cineraria acanthifolia*, a silvery-leaved plant that is to be preferred to *C. maritima*, but not as easy to propagate. It is a variety that does well when established.—*A. D. L.* The little yellow *Odontoglossum* appears to be the typical *O. odoratum*, a very variable species. The other is *O. ramosissimum*.—*T. I. & Sons.* *Clematis flammula*.—*T. L.* *Hippophae rhamnoides* (Sea Buckthorn).—*A. G. L.* 1, *Solidago serotina*; 2, *Helianthus rigidus* var. *Diana*; 3, *Helianthus rigidus*; 4, *Helianthus multiflorus maximus*; 5, *Helianthus giganteus*; 6, *Chrysanthemum uliginosum*.

NARDINA DOMESTICA: *Fr. de Lact.* A greenhouse-shrub of easy culture, thriving in sandy-peat and

loam, with much the same kind of culture as that which is found to answer with the *Camellia japonica*. Cuttings of ripe shoots strike readily in sand under a hand-glass without bottom-heat.

PERFUMES, ESSENTIAL OILS: *E. C. H.* The article enquired for appeared in our issue for May 1, 1897, p. 283. The date of the Consular Report, upon which the article was based, we are unable to furnish; but, doubtless, Mr. Jackson would be able to do so. We have no record of the experiment in "Wallflower-culture for Perfume-purposes in Lincolnshire." Much of the kind of information that you require is furnished by Mr. G. W. S. Piesse in his *The Art of Perfumery*, published by Longmans & Co.; and much may be gleaned from Maiden's *Useful Native Plants of Australia*. There is a very large amount of information in the *Gardeners' Chronicle* as to the cultivation of perfume-plants at home, but time fails us to hunt for it. As you are seeking for information concerning flower-production in the colonies, they ought to be able to assist you at the Imperial Institute, South Kensington; and at the Royal Botanic Gardens, Kew.

PLAN OF A MAZE: *H. J. C.* A plan appeared in these pages on February 10, 1849, the same being reproduced in the issue for March 5, 1892. It was taken from *The Theory and Practice of Gardening*, by John James, 1712.

R. H. S. JOURNAL: *W. L. H.* The *Journal* appears more than once a year. You should apply to the Secretary, 117, Victoria Street, Westminster.

SEEDS: *H. C.* We have no knowledge of white-flowering plants having seeds of a low degree of vitality; their seeds, as a rule, vegetating as freely as those of plants having coloured flowers. There is nothing in your statements in regard to these matters.

SETTING OF CUCUMBER BLOSSOMS: *G. H.* Had you furnished us with the necessary particulars as regard to your management of the plants, the question you put to us would have been less of the nature of a conundrum. We are glad, however, that you have discovered the reason that the blossoms failed to "set."

SKIN ERUPTION SUPPOSED TO BE CAUSED BY SPERMANNIA AFRICANA: *W. E. H.* We have no knowledge of any ill effects arising from the contact of the skin with the leaves, shoots, &c., of this plant. Perhaps some of our readers would kindly give their experiences.

SMILAX OFFICINALIS: *Fr. de Lact.* This name is given to three or four different species of *Smilax* by many different authorities. Most *Smilaxes* are hardy in the temperate zone, and present no difficulties in their cultivation. They prefer a sandy-loam, good drainage, not much manure, and a sunny aspect.

TUBEROUS-ROOTED BEGONIAS: *L. S.* Very large high-coloured varieties, but not differing greatly from scores of others found in gardens. Whether they are adapted for bedding-out will depend on the pose of the flowers, habit, &c. of which these sent do not allow us to form an opinion.

COMMUNICATIONS RECEIVED.—Subscriber.—*C. Rookell*.—*C. Best*.—*St. Andries*.—*Roberts*.—*W.*.—*Jas. Hughes*.—*I. R.*.—*S. N.*.—*W. J. B.*.—*T. K.*.—*Protheroe & Morris*.—*A. R. S.*.—*J. Backhouse & Sons*.—*M. C. Z.*.—*Z. W. D. H.*.—*F. S. G.*.—*J. W. W.*.—*G. T. K.*.—*C. & Co.*.—*J. B. Davy*.—*California*.—*M. T. M.*.—*J. B.*.—*Bailey Waddis* (many thanks).—*D. H. W.*.—*E. C. CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the pleasure of announcing that the circulation of the "*Gardeners' Chronicle*" has, since the reduction in the price of the paper,

MORE THAN DOUBLED, and that it continues to increase weekly.

Advertisers are reminded that the "*Chronicle*" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

THE

Gardeners' Chronicle.

SATURDAY, SEPTEMBER 25, 1897.

LAMPOR T.

THE practised observer of British domestic horticulture is occasionally the witness of features in a particular garden that are unique. He notes the result of certain methods of culture, differing absolutely from those to be found in any horticultural manual; they are, in fact, original in conception, and consequently peculiar to the place.

Sometimes it means merely that as travellers adopt various routes to one and the same place, so have different means been adopted to obtain the results sought for. Less frequently the cause is a deeper one, since a novel ideal is sought—perhaps one that numbers would unhesitatingly declare to be nothing more nor less than eccentric horticulture. Be that as it may, the probability is, that a garden which presents such deviations from the beaten road is one that will afford the visitor most interest, and will remain longest in his memory.

Such a place is Lamport Hall, an old manorial residence in Northamptonshire, 'twixt the county town and Market Harborough. It has been the home of the Isham family for upwards of three centuries and a half, and of the present Baronet Sir Chas. Isham for more than seventy years, for fifty of which he has exerted a controlling influence over many characteristics of the garden.

To know with what interest he has done this, how far he has succeeded in realising his own ideals—some of them remarkable ones, it is necessary that one should visit the place, and, under Sir Charles' own guidance, see his bowers of Box-trees, his rockery, or his walls beautifully clothed with vegetation, and hear, as we did, the theory or the reason that suggested the construction of the objects in each instance. But that is not possible to all, and the purport we have in writing this note is to convey some idea of the garden, and indicate the reasons for certain methods that have been pursued, which, however, it would be unorthodox to recommend. First, then, we may refer to—

THE ROCKERY,

the most unique spot in the garden, and one wherein have been concentrated most of Sir Charles' interest and personal work. It may be said at once that its claim to notice does not rest upon the size, for it is small, and the fact of being small may have suggested its style and character. In construction it differs widely from any rock-garden that we have seen. Sir Charles himself says, anent a rockery:—"It should exhibit a combination of opposite extremes, the utmost wildness of construction, with the highest cultivation. It should be trained that the crevices remain open to produce an effect of light and shade." Here is given, in the constructor's own words,

his idea of what he would like to produce. The highest point in the structure, and it may be seen in the centre of fig. 64, is 24 feet, and is topped by a few feet of Tree-Ivy, consequently, though miniature in area, its height is altogether unusual. Standing in front, the rockery describes an imperfect half-circle, or crescent, the highest point being also furthest from you, the sides becoming rounded until almost in a line with the beholder. Except by a narrow entrance which abuts on the mansion, this feature of the gardens at Lamport is entirely hidden from view, and probably there are few rockeries nearer the residence than this one. The disadvantages of site, however, in the present case, are few—indeed, one only, that on one side it adjoins a conservatory. It was not planned thus, and the fault has arisen through a difficulty in procuring the stone that it was intended should have covered the site. The rockery has been described by Sir Charles as "an assemblage of small caves, crevices, excavations, and inequalities, carpeted and encrusted with a vegetation suited to the purpose." There has been no attempt to make it resemble a ruin by using columns or such objects; but its shadowy caves, its studied finish, its ruggedness, its extremes, are striking.

The Lamport rockery is not remarkable for an extensive variety of alpine plants. The intention has been to clothe it suitably, that the effect of the whole may be pleasing and picturesque, and that every plant when viewed individually should appear to be in just its right position. It is more correct to say that the plants have been selected to clothe the rockery, than that the latter was constructed for the growth of a collection of plants.

In the manner in which the plants have been cultivated there is much novelty. It may be said here that every stone of which the structure is composed has been placed in position by the owner himself, or by his direction, and in his presence. He has done the planting, and no other person has anything to do with it unless by his instruction. Close to our feet there is the common *Veronica spicata*. It happened to be in bloom, and it was noteworthy because growing luxuriously apparently upon the flat surface of a large stone. We should have been none the wiser had Sir Charles not explained that he had chiselled a small hole through the centre of the stone, and put soil into it, so that the roots of the plant could by that means reach the ground through the stone. This sort of thing occurs frequently, and in the case of different species, and affords an illustration of the amount of mechanical work that has been expended—some of the stones so treated being 14 inches thick. The hammer and chisel are always at hand, and they account for many of the plants succeeding in very strange situations. No plant that grows quickly is a favourite for this structure. Everything is in miniature, and if the plants are not so naturally, then their cultivation is directed to that end. It is full of plant curiosities. A stunted individual that refuses to make free growth is just the kind of plant that is sought. Dwarf Conifers form one of its features, and Sir Charles has been at some trouble to procure them. Some of them are known to be upwards of seventy years old, and have not made more than 3 feet natural growth. But besides being of this great age, many of them have also to support Ivy, which, planted at the foot, has run—well, just as much over its host as it is allowed to do, for the smallest plant is "cultivated," and limited as to size. These aged Conifers include several

Spruce Firs that came from the Royal Exotic Nursery of Knight & Perry at Chelsea, now owned by Messrs. J. Veitch & Sons; also several *Retinosporas*, silver and gold-coloured forms of *Lawson's Cypress* (Ivy-clad), and others. But the strangest looking object amongst the Conifers is a diminutive fir, probably seventy years old. It has five straggling roots, the ends of which only have penetrated between the stones, whilst a few inches of each, and the base of the plant are suspended and disclosed. Evidently when the plant had become established, the stones have been picked away from the roots so far as it was safe to do this. Thus to a large extent, the root system as well as the part that is usually above ground, may be seen.

The Utah Agave (*A. utahensis*) grows on a piece of rock a few feet from the ground, in as perfect a position as this Alpine species could be given. A few plants of the Japanese Maple (*Acer polymorphum*) in close proximity appear very suitable, and have made little growth, although planted as long ago as 1869. Here and there is the variegated Box; and occasionally over the rocks and caves, hangs a variegated Bramble. At the present time this Bramble is a very pretty sight, the foliage is beautiful, and the canes bear abundance of fruit. Yonder one sees the curled-leaved variety of the common Tansy (*Tanacetum vulgare*), and the alpine Strawberry in more than one spot clothes a projecting piece of rock with its pretty leaves. Over a good part of the rockery the Spider House-Leek (*Sempervivum arachnoideum*) creates a silvery effect, distinct and pleasing. We have not previously seen this species growing so freely and happily. A *Thalictrum*, or Meadow Rue is noticed, and a hardy species of *Euphorbia*, about 6 or 7 inches high, with dark green leaves, gives another aspect entirely to the part it covers. This species never flowers here, and contrary to the circumstance being considered a disadvantage, it is appreciated, for, said Sir Charles, "Species that do not flower on the rockery usually present a good appearance for the greater part of the year, but flowering species are apt to look 'weedy' directly they have bloomed." In the spring, however, almost the whole face of the rockery is clothed with *Aubrietia deltoidea*, and it is a sight not to be forgotten. But it is not necessary to further remark upon the species of plants, for they have been chosen from different reasons entirely to those that would count with the average gardener. Two other features of this rockery, moreover, call for mention: the first is that of the Crystal Caves situate on the right-hand side of fig. 64, and formed of quartz, &c., which are certainly uncommon, and produce a distinct and admirable effect. The second, is that of the pretty miniature figures or models a few inches high, that represent gnomes or fairy miners at work in the caves and crevices; some have caught the trade union spirit and are "on strike," as will be seen on reference to fig. 63. The demand they make (a familiar one) is prominently displayed on a board hoisted at the entrance to a crevice. The use of miniature figures was advocated by Loudon in his *Encyclopedia of Gardening* as an appropriate set-off to pigmy Fir-trees, and his idea is explained by woodcuts on pp. 28 and 29 of the edition of that work published in 1850. They certainly increase the weirdness and novelty of the scene; whilst the positions some of them have been placed in at Lamport are suggestive of reality. One of these is lying at full length upon a rock gazing over the ledge; at others, apparer

walking beneath. But the first object that fixes the attention, and even startles most visitors, is a life-size figure, in terra-cotta, of a young lady sitting upon a rock reading a book, which is held in her hands. She has evidently been engaged in tending the plants, for a watering-can stands close to her side. This figure was seen some years ago at an exhibition at Brussels, and later Sir Charles Isham purchased it from a dealer in such things in Oxford Street, London; since being stationed upon the rockery, two presents have been made her; a hat and a diamond ring. The figure is so good that it is invariably mistaken for an actual person.

We must hasten to notice features other than the rockery, however, yet not before mentioning an old plant of *Ampelopsis Veitchii* that covers the wall opposite. We said "cover," but that is not strictly correct, for Sir Charles, as he pulled away a few leaves and young shoots, remarked, "It would grow all over the wall if I would let it." That is not desired; the wall must be made visible in some places, and the thick stems of the plant are objects of admiration that require no clothing, at Lamport, at least.

Before leaving the scene we noticed a flag displayed, and in letters upon the wall may be read, "Fifty years old! This is the Jubilee of the rockery, commenced in 1847."

THE BOX BOWERS.

The pleasure-grounds may not boast a representative collection of the best kinds of trees, but in their Box Bowers and Box-trees (*Buxus sempervirens*) generally, they possess a characteristic, that so far as our experience goes is without a parallel. These Box Bowers are said to have been planted by Sir Edmond Isham about 140 years since. Some of them appear to suggest that originally the Box was planted around small groups of forest trees as an edging merely, but they have since thriven in such an extraordinary manner that, by degrees, the central trees have been removed, the Box has filled the space, and it has grown to a height of 20 or more feet. The branches have also extended laterally to a great distance, and the lower ones falling upon the ground, have become layered naturally. Sir Charles Isham has opened each of the groups in such a manner that they present deep shadows in the landscape, that are visible from the residence. One of the groups is represented by fig. 65, and on reference to this, it may be seen how Sir Charles has cut away some portion of the foliage and side-shoots in order to disclose the handsome stems of the taller trees. But in this instance the stems are not so striking as in many others. The figure represented at the entrance to the bower is that of the present Sir Charles Isham. The vigorous growth of Box throughout the pleasure-grounds is phenomenal, and the distinctive appearance it imparts to them may be imagined. Many of the stems have a diameter of more than 4 inches. The variegated variety also grows freely, and there are many instances of it found upon the walls, and as trees of considerable height.

PICTURESQUE WALLS.

In the pleasure grounds at Lamport are several high walls of rough stone, such as may occasionally be found in other very old gardens. Modern gardens rarely possess walls that are not utilised for the protection and support of fruit trees, and when in a rare old place, that, with other features indicative of a past century, there are such walls as exist

at Lamport, we are charmed by them. But the beauty of those of Sir Charles Isham's is greatly enhanced by the perfect manner in which they are clothed. They assuredly exhibit taste of an uncommon degree, and appeal to one's sense and appreciation of the beautiful. Very opposite treatment indeed has been practised in the case of the plants growing against these walls to that under which other species grow in the rockery, or even in the pleasure-grounds. Abundance of freedom characterises the growth in all instances, resulting in such complete absence of stiffness or formality as we have seldom observed elsewhere. A fine old plant of *Wistaria sinensis* with its large limbs, embraces one of the walls for a very considerable distance, and though less in its dimensions than the large plant at Hampton Court, its size is sufficient to remind one of that specimen. It is a glorious sight when covered with its pendulous racemes of delicately-coloured flowers; and even out of bloom the appearance of the plant is decidedly good. A purple-leaved Vine loosely hides the wall in another aspect, and near to this is a bold-looking plant of the dangerously poisonous *Rhus toxicodendron* from North America, and sometimes known as the Poison Ivy and Poison Oak. The plant upon this wall is probably the variety *radicans*, figured in *Bot. Mag.* t. 1806, as *R. t. vulgare*. But no plants appear to better advantage upon the walls at Lamport than the varieties of Ivy. Frequently there may be seen beautiful pieces of Tree-Ivy above the wall, similar to that which crowns the highest point in the rockery; whilst of silver variegated varieties, and a golden-coloured Ivy, there is an uncommon wealth, and the beautiful colour is phenomenal.

THE YEW TREES, &c.

A path known as the Eagle Walk runs through an avenue of *Taxus baccata fastigiata*, which have grown, and still continue to thrive with healthful vigour. The remarkable characteristic in connection with these is the method in which the trees are trained. Sir Charles prunes each of them himself, and it is not too much to say, that there are not two of them of the same appearance. The most that one generally thinks of doing in regard to training the Irish Yew is to secure the branches that are liable to be blown out of position. Columnar in habit, the tree is generally induced to become even more so than it would do naturally. At Lamport this is not the case, and many of the lower upright branches have had their tops removed at about 3 to 4 feet from the ground level. Sometimes this is done to prevent the tree becoming dense in appearance, and again to disclose the main stem, which in a pyramidal tree is usually hidden. The avenue presents a somewhat novel picture, and a certain weirdness is given to the trees from the shapes into which they have been pruned. We might mention a few other instances of trees that are pruned in an unconventional manner, but these must suffice.

THE KITCHEN GARDEN, &c.

There is a useful kitchen garden at Lamport, exceedingly old, of course, and the walls by which it is confined support a quantity of fruit-trees. Some of these are past fruiting profitably, and a few of the Peach-trees are to be removed; but there are others of greater value, and the Pear-trees especially are remarkable for the evidence they give of past and present care in training. Vegetables are plentiful during the present season. Mr. H. Kempshall,

the gardener, showed us capital crops of Onion Potatoes, Peas, and other kinds. Celery making good progress, and first-class Lettuce and such like, in all possible places, indicate that the garden was cropped to the utmost. There were excellent Tomatoes under glass, Grapes, Melons, and other fruits looked well. We remarked an exceedingly heavy crop of indoor Peach-trees, and it will need much skill to induce them to repeat it year after year.

The few plant-houses were neatly maintained, and in the borders out-of-doors, a display of flowering-plants was particularly commendable.

Lamport Hall contains many very valuable paintings, and besides these there are numbers of interesting and curious features. These Sir Charles was kind enough to show and explain to us, but they are not exactly matters that need be discussed in the *Gardeners' Chronicle*, though two of them may be briefly mentioned. In the drawing-room is a number of dried specimens of *Gypsophylla paniculata*, which look like a bush placed in an 8-foot trumpet-glass. Upon them are fastened a quantity of the most gorgeous butterflies. The idea is to make them appear as naturally alighted thereon. In the dining-room was a permanent table decoration, consisting of some dried Blackthorn shoots covered with beautiful lichens, and tastefully mounted also *Gypsophylla paniculata* and *Cotoneaster*. The Blackthorn was collected from a very distant district by Sir Charles.

Many years ago there used to visit the grounds at Lamport thousands of visitors from Northampton and elsewhere. *Fêtes* were then in support of charitable institutions, and Sir Charles Isham was most enthusiastic in making them a success. Indeed, his gentle nature was such, that notices were placed about the gardens inviting visitors to place themselves to flowers to place in their button-holes. Sir Charles and Lady Isham are deservedly held in the very deepest affection by their tenantry, servants, and all who have experienced their goodness and courtesy. P.

NEW OR NOTEWORTHY PLANTS.

SELAGINELLA HUMILE, Jenman, n. sp.

Stems prostrate, or sub-erect, very short, slender, leafy to the base; fronds once or twice branched both sides, $\frac{1}{2}$ an inch to $1\frac{1}{2}$ inches long, $\frac{1}{4}$ to $\frac{1}{2}$ inch wide; pale straw-green, main rachis and branches angular, 1 to 2 lines wide over the leaves; leaves spreading, lax, not imbricating; linear-sub-acute, the base oblique, $\frac{3}{4}$ to 1 line long, ciliate-edged; minor leaves minute, ovate, conspicuously aristate, slightly keeled or not, densely imbricated; spikes very short; quadrate or flattened, dense, keeled, cuspidate.—Trinidad, Indies. It comes in between *S. caribensis* and *S. albonitens*, and is a very small, soft, delicate species.

SELAGINELLA MAZARUNIENSE, Jenm., n. sp.

Stems stout, stiffly erect, one to two spans sub-angular or cylindrical, ligaceous, brown or ashen, laxly clothed with appressed sub-ovate like leaves equally from base to top, the stem being freely between; fronds ample, quite erect, late, 12 to 18 inches wide and deep, consisting of spreading dichotomously-branched, flat divisions, lower largest and more compound; the branches spreading, and $\frac{1}{4}$ to $\frac{3}{8}$ inch wide, tapering outwards, the fertile ones truncate at the top 10 inches long, the margins serratifid; major branches spreading, falcate, imbricating acutely, slightly ciliate at the oblique base, a line wide, 3 lines long.

iliate; minor leaves minute, appressed, ovate-cuspidate, in a double series, very dense; spikes 4-gonal, tail-like, 2 to 3½ inches long, pendent; bracts densely imbricating, sharply keeled, mucronate — upper regions of the Mazaruni River, forming dense thickets. The finest species in the colony, the barren fronds resembling most those of *S. Parkeri*, but differing in particulars. Its principal difference from any other local species is in the long, slender, tail-like spikes, resembling those of several *Lycopodiaceae*, such as *L. guadalupianum*, although not branched. *G. S. Jenman*, *Demerara*.

SAFFRON CULTIVATION IN KASHMIR.

In an interesting volume on the *Valley of the Kashmir*, by Walter R. Lawrence, are some notes on the cultivation of Saffron, from which the following

tried in vain to cure him. Baffled, the physician at last asked the water-god whether he was a man, and on finding out that he was a Nág, he at once saw that the remedies applied to the Nág's eyes were nullified by the poisonous vapours which issued from the water-god's mouth. He bound his eyes with a cloth, and the Nág was restored to health. In his gratitude, the Nág gave the physician a bulb of Saffron, and the cultivation sprang up at Padampur, now known as Pámpur. The system of cultivation, it is said, suggests the idea that it is unnecessarily slow and primitive, and the European methods of producing seed-bulbs might increase the production of Saffron in Kashmir. At present cultivation is extending as fast as the local method of seed production will allow, but that this method is slow may be inferred from the fact that at measurement of a total area of 4527 acres of Saffron-land, only 132 acres were actually cultivated with the *Crocus*. In

for planting out the bulbs is in July and August and all that the cultivator has to do is to break up the surface a few times, and to ensure the proper drainage of the plot by digging a trench on all four sides. The flowers appear about the middle of October, and the purple blooms, and the delicious, though somewhat overpowering scent of the Saffron turn the dry, uninviting plateau above Pámpur into a rare and wonderful garden. There is no doubt that the soil above Pámpur is strong, for excellent crops of Wheat and Barley are grown there. Although the cultivation of Saffron has extended most satisfactorily during the last two years, it is feared that the system of collection adopted by the farmers will have the effect of preventing the industry becoming popular, as during harvest-time the cultivators are as carefully watched and supervised as diamond-diggers at Kimberley. In former days men came from all parts of Kashmir to cultivate Saffron; but now, with

FIG. 62.—SECTION OF ROCKERY AT LAMPORT HALL. (SEE P. 209.)

acts are taken. The drug in Kashmir is famous for its bouquet, and is in great request as a condiment, as well as for a pigment for the forehead-marks of the Hindus; various substances, such as turmeric, are now used for the latter purpose by the Kashmiri pundits, but if a man can afford it, he will use the right saffron colour, mixed with red-lead, and rounded with a piece of Deodar-wood.

The cultivation of the Saffron is peculiar, and the legend about its introduction into Kashmir shows, at any rate, that it is an ancient industry. In the time of King Lalta Dit there was a famous physician at Padampur, the city founded by Lalta Dit's minister, Wazir Padam. A Nág, or water-god, fell sick of an eye complaint, and went to the physician, who

former days the Saffron cultivation was a large source of revenue to the State, but during the famine the people in their distress ate up the bulbs, and although seeds have been imported from Kishtweir, and every year land is set apart for the production of seed, the process of reproduction is slow. For seed purposes a particular aspect and sloping ground are required, and it takes three years before the bulbs can be planted out in the small square plots, where the Saffron is to be grown. These plots must remain fallow for eight years, and no manure or water given to them. When once the bulb has been placed in the square, it will live on for fourteen years without any help from the cultivator, new bulbs being produced, and the old one rotting away. The time

the exception of a few men from Trinagar, the cultivation is in the hands of local men. At harvest-time the whole flower is picked, and put into bags, and then taken to the farmer, who takes one bag for himself, and gives the other bag to the cultivator. The bags are never opened, and it has been found by experience that the cultivator never attempts to foist a bad bag on the farmer. The cultivator then takes his bag to the left bank of the river, and makes his own arrangement for sale. When the flowers are collected, the real work of extracting Saffron commences; the flowers are dried in the sun, and the trifid stigmas are picked out by hand. The reddish-orange tip forms the first-quality Saffron. The long white base also makes Saffron,

but it is of inferior quality to the tips. The Saffron thus collected in a dry condition is known to the trade as "Mougla," and fetches one rupee per tola. When the "Mougla" Saffron has been extracted, the sun-dried flowers are beaten lightly with sticks and winnowed. Then the whole mass is thrown into water, when the petals swim and the essential parts of the flower sink, the latter are collected; and the parts which have risen to the top are dried and again beaten with sticks, and then plunged into water. The process is repeated three times, and each time the parts which sink become poorer. One form of adulteration is to mix the sunken parts of the third stage with those of the first stage. The Saffron obtained in this way is lighter in colour, and of fainter scent than the "Mougla," and is known to the trade as "lacha," and sells at twelve annas per tola. The Saffron when made is sent to Amritsar and other trade centres by registered post.

PLANT NOTES.

BEGONIAS.

TUBEROUS-ROOTED Begonias, La Fayette and Worthiana, are admirably adapted for bedding-out, the former being very free-flowering, of erect habit, in colour a crimson-scarlet, and with double blossoms, its height being about 9 inches. Worthiana is single-flowered, of an orange-scarlet colour, also very free, and of dwarf habit. Beds filled with each variety, and edged with bands of Golden Feather, are now objects of special beauty in the gardens of East Burnham Park. C. H.

HIBISCUS SPLENDENS.

In Australia this species grows to the size of a small tree. Under cultivation it forms an acceptable plant for the greenhouse, and flowers continuously for several months during the summer. The stems and foliage are covered with rough hairs and small light brown spines. The axillary flowers are about 2 inches across, and the broad petals are a most pleasing tint of pinky-white. At the base of the petals runs a dark purple circle, the stamens also being of this colour, forming a good colour-contrast to the other parts of the bloom. The cultivation of the plant, when given a good rich soil, is easy.

PHYSTELMA (HOYA) CAMPANULATA.

The flowers of this species are very unlike those of other Hoyas, under which generic name it is sometimes grown. It is a climber with wiry stems, and opposite leaves in which the venation is not as marked as in Hoya, and the internodes are very long. The bell-shaped flowers are in cymes, and form quite a little bunch of buff-coloured corollas hanging from the stems. In Java the plants are said to flower the whole year. It is well worthy of a place in the stove, and needs little attention if potted in a rough, peaty compost, and afforded good drainage.

SEDUM CÆRULEUM.

This is an old plant that deserves to be more commonly cultivated, both out-of-doors and in the greenhouse. If sown in the spring the growths soon flower, and form quite a carpet of pretty, light blue, star-like flowers, which continue for some weeks. The plant does not grow more than 3 inches in height, and in a dryish border it makes a charming edging. A figure may be seen in the *Botanical Magazine*, t. 2224. *Grammanthes chloriflora*, of similar habit, producing orange and red-coloured flowers, is also a good plant.

BEGONIA PRESIDENT CARNOT.

This Begonia has been in commerce for some years, but it is far too seldom seen. For two months past a specimen has been in flower here, in a cool stove, where it is planted under the staging at the back of the hot-water pipes. The stems (about 13 feet long) are trained over the roof, and have made their way into the lantern. Just now there are about forty trusses of its large rosy-carmine female flowers; and as these hang in clusters, some of which are 9 inches

across, the effect can be imagined. For this handsome plant we are indebted to M. Crozy, and it is said to be a cross between *B. Olbia* and *B. rubra*, the latter species being probably intended for *B. coccinea*. R. L. Harrow, Royal Botanic Garden, Edinburgh.

KEW NOTES.

CRINUM BALFOURI.—This species was discovered in Socotra by Dr. J. B. Balfour when he explored that island in 1880. It flowered at Kew in the autumn of the same year, and was figured in the *Botanical Magazine*, t. 6570 (1881). A bulb of it was brought from the same island by the late Mr. Theodore Bent, who found it and other Crinums, as well as *Begonia socotrana* and other plants, when collecting there a few weeks before his death, which occurred in May last. This bulb is now in flower in the stove at Kew, and the parts of the plant are larger generally than those given in the *Botanical Magazine*. The bulb is 4 inches in diameter, the neck 4 inches long; the leaves glaucous-green, 1 foot long and 2½ inches wide. The scape is 2 feet long, compressed, and it bears an umbel of fifteen flowers, which are pure white, fragrant, with narrow spreading segments 3 inches long, the stamens and stigma tinged with pink. It comes nearest the new *C. Woodrowi*, recently introduced to Kew from Bombay.

THE KEW BELLADONNA LILY.

There are four large flower-heads of this magnificent variety in full blow in front of the Orchid-houses at Kew, and by the side of them is a border crowded with flower-heads of the common form. The difference between the two is most marked, the scapes of the Kew variety being twice as long and correspondingly stout, the number of flowers in the umbels four times as great, whilst the flowers are of a rich rose-crimson colour. How this variety originated is uncertain. It was said to have been obtained by crossing *Amaryllis Belladonna* and *Brunsvigia Josephina*, but there are no traces of the *Brunsvigia* in the Kew plant. There are young plants at Kew which are certainly the result of crossing the *Brunsvigia* with the *Belladonna*, but they are only about two years old. Meanwhile let me recommend the Kew *Belladonna Lily* to large growers of bulbs in such places as Bermuda, Natal, &c. A few thousands of it would find a ready sale in England. It is by far the handsomest autumn-flowering bulbous plant I know of.

THE BERMUDA LILY.

This is now flowering freely both in the temperate-house and in the open air at Kew. The usual time of flowering for this Lily is from April to June, according to the treatment it receives, but it appears that the season may be lengthened by securing bulbs that have been grown in Natal, the bulbs now flowering at Kew having been purchased at the auction-rooms in April last. They were advertised as having been grown in Natal, and about 4000 were sent over to England for sale as an experiment. Judged by the plants at Kew the experiment is a complete success. The bulbs when sold were equal to the best samples received from Bermuda, but they realised less than is usually paid for good bulbs in September. The enterprising person in Natal who sent these bulbs should send more next April, and those who want good white Lilies in September should buy them.

GLADIOLUS PRIMULINUS.

and a pink-flowered *G. oppositiflorus*, are two interesting species now flowering in the collection at Kew. The former was described in 1890 from bulbs flowered at Kew in 1890, whither they had been sent from the Usagava Mountains, in East Tropical Africa, by Mr. Missionary Last. It has the habit of, and is quite as sturdy as *G. dracocephalus*, whilst the flowers are of an uniform primrose-yellow colour. It is well worth the attention of breeders of *Gladiolus*. It flowers and seeds freely at Kew every year. The second species was lately received from Mr. Howlett, of Uitenhage, who obtained it from Matabeleland. The type, noticed in the *Gardeners' Chronicle* in March, 1893, p. 291, has white flowers, on spikes

4 feet or more high; but this pink variety has about a yard high, which are crowded with coloured of a rich pink, with dark crimson petals. It did not flower until the present month, and is little chance of its ripening seeds this year. *Oppositiflorus* is one of the parents of the garden section of *Gladiolus*, it is remarkable that it flower very late in the year.

URGINEA SCILLA.

A large bulb of this, the plant from which is obtained, is now bearing a tall spike of flowers in the Cape House, at Kew. If it were to flower frequently under cultivation in this country it would deserve to rank among useful bulbs for the house, the inflorescence being not unlike that of the smaller species of *Remurus*. The bulb is 6 inches in diameter, and leafless; whilst rising from its centre is an erect spike 1 yard high, the half clothed with star-shaped white flowers, measuring an inch across. The leaves, which are developed in the winter, number about twelve, and are strap-shaped, about 1 foot long and 2 or 3 inches wide. The plant is found abundantly in the bordering the Mediterranean, the Canary Islands, from whence the bulbs are imported to be sold dried for use as a medicine.

A YELLOW IXORA.

According to botanists, this is one of the varieties of *I. coccinea*, but for garden purposes requires a distinctive name. It is *I. coccinea lutea* of the Ceylon Botanic Garden, whence plants have been obtained for Kew, and have flowered freely in a stove this year. The form compact shrubs about 1 foot high, with green-ovate leaves, 4 inches long by 2 inches wide and terminal, rather loose cymes of buttercup flowers, each with a tube 1 inch long, and 1 inch across. The plants continue to push out from the base, which flower when about 1 foot high. *I. coccinea* is widely distributed throughout both wild and as a garden plant; but this flowered variety is only known to occur in India. It may conveniently be called *I. lutea*. W. H.

THE ROSARY.

THE ROSE GARDEN IN SEPTEMBER.

A VERY great mistake is, I think, sometimes made by amateur Rose-growers, who think that when the summer bloom is over the plants may be left to themselves. It is the way with a good many when people have got all out of them that they neglect them, and leave them to their fate. Thus, if you go to the rosary now, you will find strong shoots with half-a-dozen blooms each, which, in the earlier months of the year, have been closely disbudded—and yet surely coloured Duke of Edinburgh or a Mrs. John are more valuable now than they were when the garden was full of Roses. Therefore I think it is one point that has to be looked to in September, and if the Rose-growers have returned from holidays, when probably their plants have had time of it, this should have attention.

There is another point which I have of late urged upon Rose-growers, viz., the desirability of leaving all the pruning to be done in the spring, have at one time or another to get rid of the ing wood of the current year, and of such shoots as would be unlikely to give us good. When should this be done? The general opinion would, no doubt, be—oh, of course, in the autumn, but from this opinion I differ. I think it is better to get rid of it now, as by so doing more light into the plant, and consequently the ripens and hardens better. There have been many differences of opinion as to the value of ripening; but I should think the general conclusion of opinion would be that it is a most important factor in obtaining good results in the next year, and therefore I would say, cut out all that is not wanted for next year. Of course

only of dwarfs, on whatever stock they may be grafted. Although for a long time during the dry of July the growth of Roses seemed almost standstill, yet when the rains came it was not to see how rapidly the plants sent out from the underground stems; these are the ones on which we depend for our next season's crop.

And here let me give a word of warning: that you have plants budded on the Manetti you watch the stocks very carefully, and see that you are not encouraging their growths instead of those of the roses. The foliage is misleading, and, unlike the leaves of the Manetti, is not easily distinguished from that of many roses which are budded on it; and it is no uncommon thing to see even in good gardens a flourishing of the stock, while the scion has completely died. It is desirable also in exposed situations to see that the long and juicy shoots should be cut against the wind—and what winds we had this year! The best way to do is to place a stake to each of them; of course,

that I have plants in my garden which have been budded for upwards of forty years on the Manetti, and yet are strong and healthy—and I do not think more than this can be expected of own-root roses. Should, however, anyone wish to make cuttings, the present is the best time for doing it; shoots of about 9 or 10 inches long are the best suited for this purpose—a place should be prepared for them in a shady border, the soil should be light, having a good proportion of sand in it. It is indifferent whether the cuttings have a heel or not, but care should be taken that nearly the whole of the cuttings should be buried, leaving only one or two joints above the ground. The eyes of these joints which are buried, had better perhaps be taken out with a sharp knife; and it may be desirable to put a frame over the bed in severe weather. The Americans are somewhat fond of Rose-propagation by cuttings, but with them bottom-heat is used to a great extent, and the plants are grown more for the purpose of producing flowers than for making good plants. They

I do not refer to standards or half-standards, which many amateurs bud for the purpose of obtaining maiden blooms.

When new beds have to be formed (and, of course, all who really love the Rose will be anxious to give it a place to itself), now is the best time to be preparing them. We constantly hear complaints of amateurs having a bad soil for Roses, but this is a matter which can in most cases be remedied. The soil which the Rose prefers is that of a good greasy-loam; but all of us do not live in Hertfordshire or Essex. Good drainage is, however, one great essential, and when the soil is too retentive, artificial drainage should be resorted to; but I am more than ever persuaded that a good climate is a better factor in successful Rose growing than a good soil. It is in most cases possible, to make a bad soil into a good one by procuring some cart-loads of good loam; and this should now be obtained where necessary, and well dug in, and the bed left in a rough state until the time for planting comes on. The question as to whether manure should be used at the same time is a much debated one, but I think, on the whole, it is safer not to make use of any. The amateur having made all these necessary preparations, may now con the Rose catalogues, and look through his Rose-beds, in the one case to decide on what new varieties he shall introduce, and in the other what plants he will discard. It is early enough to carry both of these into execution, but it is well to be forearmed, for when the month of October comes there are so many things in the garden to be thought of, that it is well to clear these matters away before that month sets in. *Wild Rose.*

FOREIGN CORRESPONDENCE.

LILY-BULBS AND OTHER CHINESE FOODS.

THE several thousands of Chinese resident in San Francisco are remarkable for their aversion to "white devils' bread," and for using in its stead a number of articles, either imported at considerable expense direct from China, or grown by them in the rich alluvial valleys of California. One may frequently see offered for sale in the provision-dealers' stores in China-town, San Francisco, large baskets of yellowish-white Lily-bulbs, with large scales. Enquiry elicits the information that these bulbs are eaten as a vegetable by the Chinese, after being lightly boiled. I have made several attempts to grow them in the Botanic Garden of the University of California, but without success until the present season, probably owing to lack of moisture. Last March, however, I obtained two fine bulbs in China-town, and planted them in the light soil of a shaded rockery, subject to daily watering, and on August 21 one opened a fine blossom, which proves to be that of *Lilium japonicum*, var. *Browni*.

Among other things frequently met with in the provision stores of China-town are:—tubers of arrow-head, *Sagittaria latifolia*, Willdenow; the long white roots of Chinese Radish, *Raphanus chinensis*; young plants of an *Amaranthus* neatly tied up in bundles; the young shoots and flowering tops of the Chinese Cabbage, *Brassica chinensis*; sprouted seeds of the Soy Bean, *Glycine Soja*; black, white and green seeds of *Glycine Soja*, and a small, square, white cheese made from the same, wrapped in a yellow cloth, and bearing a brown Chinese monogram; "stones" of Ginkgo fruits (*Ginkgo biloba*); tubers of an Aroid (*Colocasia*?); rhizomes of Chinese Ginger (*Zingiber* or *Alpinia*?); Yams, tubers of species of *Dioscorea*; sea-birds' eggs from China, each wrapped in a plaster of wet dung or clay; dried octopus; ducks skinned, spread out, and dried; dried clams; dried cuttle-fish; pork, fresh, roast or dried; seeds of *Nelumbium speciosum*; water-melon seeds; and numerous articles the botanical or zoological origin of which I have not yet discovered.

The drug-stores of China-town are equally remarkable. In them one can usually obtain a panacea for all ills, varying in the number of ingredients according to the price paid (25, 35, or 50 cents). This prescription usually contains a few slices of the root of a *Glycyrr-*

FIG. 63.—SECTION OF ROCKERY AT LAMPART, SHOWING THE FAIRY MINERS "ON STRIKE."
(The figures are about 3 inches high. See p. 209.)

has great play on them, and unless in some such way as this, they will get considerably damaged, and oftentimes the whole plant is about, leaving a hole which in a wet soil is apt to get filled with water, and so injure it. For the same reason, where the shoots are long, they often do it, it is to slightly shorten them.

This is a subject which at this season of the year to attract some amateurs, I mean that of Roses on their own roots. We are being told how much more natural, and, how much better such a process is. We are told that it is a more rapid method of growing and that they live longer. To both of these I demur; many Roses raised from cuttings slow in getting hold of the ground, and it is of years before any good return is given. I have, and then, it is true, seen some good results, none whit better than if the plants had been

I have never found that what we call Roses do any better on their own roots. I have seen such varieties as Horace Vernet, Louisette, or Reynolds Hole doing well in this way, and as to their longevity, I can only say

are not turned out-of-doors, and after they have served the purpose of flowering, they are in most cases cast aside. Considering the cheap rate at which Rose-plants can now be had, I do not think that any amateur would trouble him or herself with this method of propagation. I feel that in writing this, that I am like the cook who gave directions for dressing a pike, who, after giving elaborate instructions as to how it was to be stuffed, and the care with which it was to be cooked, added, having done all this, "pitch it away." So I would say to those amateurs, do not trouble yourself about Roses on their own roots—in fact, many of our largest amateur growers do not propagate their own Roses; they prefer going to some nurseryman in whom they have confidence, and obtaining their plants from him. There may be advantages in budding your own plants; you may be more sure of selecting good flowering-wood, and so not be disappointed when the time for blooming comes on. But, knowing how very careful Rose-growers are in all that pertains to budding, and how anxious they are to maintain their reputation, I think the matter may be safely left in their hands, and I am sure that a great deal of trouble and worry will be avoided by carrying out this plan.

rhiza; the bark of a tree—"him make heap strong," said my suave, almond-eyed druggist—dried flower-heads of a composite plant, dried cockroaches, dried cockchafer—"him good make see far," said John, pointing to the large eyes of the creature; and the skin, head, and tail of a lizard, stretched on thin sticks. An extra five cents will procure a dried "sea-horse;" and yet another five cents, a dried fish of peculiarly narrow shape, and about 4 inches in length. The black-capped, pig-tailed assistant makes a paper package of the whole, and deftly ties it round with a grass-like leaf, of Chinese origin. Before leaving I asked how the medicine was to be taken, and was told to boil all the ingredients together, make a tea of them, and to drink the same whenever troubled with heart-burn, toothache, cough, dimness of sight, or other ailment. *Joseph Buritt Davy, University of California, Berkeley, U.S.A.*

ORCHID NOTES AND GLEANINGS.

LÆLIO-CATTLEYA × *CLIVE* (C. *DOWIANA* ♀, *LÆLIA* *FUMILA* *PRESTANS* ♂).

A VERY fine bloom of this handsome hybrid, raised by N. C. Cookson, Esq., of Oakwood, Wylam-on-Tyne, is sent us by his gardener, Mr. Murray. The sepals and petals of the flowers are of a bright rosy-purple; the peculiarly-formed lip, which is nearly 3 inches broad, is of a bright tint of purple with lilac apex and orange-and-brown markings in the base and middle area, and velvety in texture. The flower has the fragrance of the Rose. It resembles *L.-C. Ingrami* (*L. Dayana* × *C. Dowiana aurea*), but may readily be distinguished from that variety. *J. O'B.*

HOULLETTIA BROCKLEHURSTIANA.

This species is probably the finest of this small genus, and is a source of attraction whenever it is in flower. In a healthy condition it is a strong grower, forming large pseudo-bulbs of a roundish shape, which bear single leaves, the blades of which are about 18 inches long, borne on a rounded petiole 1 foot in length. The basal inflorescence is nearly erect, and stands well above the compost. A plant in the Cattleya-house of the Edinburgh Botanic Gardens bears two spikes, one of which carries eleven, and the other six fragrant flowers. In colour these are of a reddish-brown, spotted with purple, and the sepals are tipped with brown. Another species, *H. odoratissima*, a Columbian plant, is also coming into flower. Both are grown in the Cattleya-house, and are afforded a good supply of water when growing.

MASDEVALLIA CORNICULATA

is very distinct in the colour of its flowers, which are brownish-red, curiously mottled and spotted with yellow, the tails also being yellow. They are borne on pedicels scarcely as tall as the foliage. The tube is very broad; indeed, this is the feature of the flower. A variety named *M. c. inflata*, said to be of a more yellow colour, with less spotting, was introduced in 1881 by Messrs. Bull; and the type made its appearance four years earlier at Messrs. Backhouse & Sons, having been obtained for them by their collector at an altitude of about 9000 feet in Colombia. *R. L. H.*

FLORISTS' FLOWERS.

THE AURICULA.

THE season appears to have suited the Auricula remarkably well. That there has been loss of plants goes without saying. The rarest and most carefully-tended collections are not exempt from loss; the insidious rot, canker, the devouring grub, &c., destroy some, and too often the more valuable varieties. Green-fly has given but little trouble, and it can always be kept under without difficulty.

There are two periods of growth for the Auricula—one which commences in January or February, indicating that the time of blooming is approaching; the other is in July and August, when it develops

vigorous leaves. Growers, as a rule, like to re-pot their plants previous to the second period of growth, so that the plants may have the advantage of fresh, sweet soil.

Change of quarters is highly desirable during the summer months. There is nothing like an open north exposure, especially if the position be a cool and shady one, yet exposed to the sunshine for several hours daily.

Free and ample drainage and porous soil are advisable at the summer potting; 1 inch deep of drainage is desirable, and some growers give 2 inches. I find that the most healthy plants are those in soil which dries quickly; and the plants will bear a little drought without receiving harm. It is when the soil becomes dry, and remains so until the young root-fibres perish, that harm is done.

At the time of potting, it is usual to take off any rooted offsets, and re-pot them singly in small pots if the offsets are large enough, or if small, place a few round the sides of large pots. Dryness at the roots must be guarded against when the young stock is making roots; enough moisture to keep them active is sufficient. The frequent addition of young stock of leading varieties is most important, as it is only in this way that a collection of Auriculas can be maintained in vigour. Sometimes a plant appears to become weak for some reason, and fails to make growth. When this happens, it is a good plan to make an exchange with some grower at a distance, and especially with one living in a northern county. The reason why some old varieties of fine quality remain so long in cultivation is, that they are well cared for. A plant of an Auricula will last for many years, and it has been well said that "the span of human life may not suffice to measure the lifetime of an Auricula." I have inherited some old varieties which have been grown for a good part of a century, and may be cultivated for yet as many more years; and varieties are now being raised which may find as great favour with our descendants. But some do wear out in course of time, showing signs of the approach of old age by becoming less constant in character. Every one who succeeds in raising a fine new Auricula which displays permanence of character, is a benefactor to those who care for and cultivate this fascinating flower. *R. D.*

THE HERBACEOUS BORDER.

EUCOMIS PUNCTATA.

THIS useful Cape bulb forms a desirable subject for general decorative purposes at this season, when simply grown on in 5 or 6 inch-pots. For room decoration it is admirably adapted, lasting at least a fortnight in good condition in an ordinary living-room. A moderately strong bulb in a 5-inch pot produces a spike 18 inches to 2 feet high of its starry, wax-like flowers, which are whitish, and spotted with rose, and possesses an agreeable fragrance. My principal object, however, in penning this note was to recommend it for a position in the herbaceous border or the flower-garden, where, if planted at 5 or 6 inches in depth in a moderately light and well-drained soil, it forms at this season an object of beauty. It is most effective when planted in a group on a sloping bank. A few days since I saw a very fine group in full bloom in a position such as this in the gardens of East Burnham Park, Slough, and the effect was both striking and unique. The flower-spikes last fresh for a considerable time after being cut. *C. H.*

ASTER AMELLUS.

The autumn-flowering perennial Asters are later in flowering this year than I have ever before known them to be, and late-flowering varieties, such as *A. turbinellus* and *A. ericoides*, unless October is warm and genial, will not reach flowering at all. *Aster Amellus* did not begin to flower till September—a full month later than usual. The very backward spring made these plants late in starting, and during the hot and dry July they made no progress, and some were burnt to death. Being in Savoy last autumn, near

Aix, where *A. Amellus* abounds wild by roadside everywhere, I was surprised to find how little it varies there, and how entirely it differs from *A. Amellus* of English gardens. The wild plant is altogether smaller, and the flowers, both the disc and the rays, less than half the size. It is possible it has been improved by cultivation and selection of seedlings; but I rather think that it is a superior variety which we have, perhaps var. *Bessarab*, which I have never seen as a wild plant. I have a white variety which was collected in Savoy, but it is dull, and the rays few, and it is a plant of little merit. It comes partly true from seed, but two or three generations has shown no tendency to improve. *C. Wolley Dod, Edge Hall, Malpas.*

THE WEEK'S WORK

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maidenhead.

The Herbaceous Borders will require attention the removal or partial cutting-back of withered stems and blooms of such plants as *Paeonies*, *Delphiniums*, *Aconitum*, *Sunflowers*, and others. Since the weeds have sprung up freely; therefore, when the surface is in a sufficiently dry state, use the Dutch hoe frequently.

General Work.—If fine weather continue, it, accompanied by frosty nights, the bedding-plants generally will make a fair display up to the end of the month; and to preserve a tidy appearance as long as possible, continue to remove all decaying leaves and flowers. Subtropical plants, such as *Cannas*, *Ricinus*, *Hedychiums*, *Abutilons*, *Fuchsias*, and some of the foliage plants, are now looking better than ever, while the yellow-flowering *Cassia corymbosa* is blooming profusely. The propagation of all the plants should be completed without delay. A number of plants should be struck in pots or small boxes sufficient numbers for providing cuttings in the spring. Clean growths should be selected for cuttings; the youngest shoots that are quite free from flower at the points being the best. If *Lobelias* of the *L. speciosa* type are propagated by cuttings, cut over a few of the plants from the least conspicuous position of the garden; and pot-up these a little later, and they will furnish plenty of spring cuttings. *Dahlias* should be examined, and either the colour of the flower or name placed to each where these are missing, or names on existing labels have become illegible.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorset.

Schomburgkia tibicinis.—*S. Sanderiana* and *Kimballiana* are quite distinct from other Orchids having hollow cow-horn-like pseudo-bulbs. The plants are now growing freely, and should be placed in such a position in the warmest house as will expose them to full sunshine. They should be well supplied with root-moisture until growth is completed, the flower-spikes are seen emerging from the crevices of the new pseudo-bulb. Gradually lessen the supply of water at this stage until the flowers fade, and then place the plants in a cooler and drier atmosphere. Other species such as *S. undulata* and *S. Lyonsii*, may be given the same cultural conditions. *S. crispata* and the closely allied *Lælia superbiens*, will thrive if placed among the *Cattleyas*, and treated similarly to those species.

Catasetums and *Cynoches* at this period should be placed on the south side of the hottest house, and pended well up to the roof-glass. Until the growths are completed and the leaves commence to show colour, an abundance of water should be given to them. Any of these species now showing their flower-spikes will require generous treatment until the spike is cut, when the plants may be suspended in full light in a cooler and drier house. Until the leaves have fallen, they must be kept moist at the roots, afterwards, if thoroughly well ripened, they require but little or no water throughout the resting period. The varieties of *Mormodes* grow in the temperature of the *Cattleya*-house and be treated similarly.

The Mexican Division.—*Lælia anceps*, *L. autumnalis*, *L. albidula*, *L. Gouldiana*, *L. furfuracea*, *L. pedicularis*, *L. majalis*, *Cattleya maxima*, *C. speciosa*, *Luisia Amesiana*, *L. Kimballiana*, *L. Psyche*, *Vittaria*, *V. Amesiana*, *V. Kimballiana*, *Epidendrum*, *Randi*, *E. atro-purpureum* (*macrochilum*), *E. cili-*

cine, *Oncidium splendidum*, *Odontoglossum Lodenboroughianum*, *O. citrosum*, *Cyrtopodiums*, *Barkerias*, &c., will henceforth require only the thinnest of shading at any part of the day.

Cattleyas.—The majority of the *Cattleyas* will stand more direct sunlight at this season than at any other. By gradually exposing them to more light and air, the newly-made pseudo-bulbs and leaves become hard and well-ripened, conditions which greatly assist them to pass through the winter safely. Where such plants as *Vanda tricolor*, *V. suavis*, *Trichopileas*, *Miltonias*, *Coelogyne elata*, *C. grammifolia*, *C. Cummingi*, *C. corrugata*, *C. fuliginosa*, *Cymbidiums*, and the cooler-growing *Cypripediums*, are placed in the same house as the *Cattleyas*, they should be put at one end, and be carefully shaded from strong sunshine.

Eslophiella Elisabethae has made a considerable number of new growths, and the plant is beginning to root freely from the rhizomes. The present is a good time to re-pot the plant, and being a vigorous-rooting species, it should be placed in a rather large pot, and with a one-fourth less depth of compost than is afforded to *Orchids* generally. It will root freely in well-drained peat and sphagnum-moss. Place the plant on the shady side of the hottest house, and afford it copious waterings throughout the growing season. Preserve a constantly-moist atmosphere around the plant, or thrips and red-spider will injure the foliage. The new *E. Peetersiana* may also be re-potted now, and treated similarly.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leobury.

Peaches and Nectarines.—Trees that have made strong growth, and especially young trees, may require to be root-pruned, and as the leaves will soon fall from the trees in the earliest house, the work may be proceeded with at once. Take out a trench around the tree sufficiently far from the stem to catch the points of the roots, then fork backwards towards the tree till a sufficient quantity of the roots are exposed; which shorten back according to the strength of the tree, and if very strong, right back to the ball; then fill in firmly with the old soil. Should any of the roots look other than clean and healthy, the old soil should be replaced with some fresh, moderately heavy loam, and a liberal addition of sound lime rubble, carefully relaying the roots as the process of filling up goes on. We examine the roots of all our trees every year in this way, taking care to keep a sufficient distance from the trees, and we thus are sure where the roots are and what their state is, and can therefore afford nourishment without waste. If advantage be taken of wet days for effecting the root-pruning of inside trees, the labour is missed but little. If any trees are to be removed and others brought in, the decision must be determined very soon, and preparations made for carrying out the work. If the work be done before the leaves fall, good-sized trees can be moved with very little check. We moved large trees from inside to out-of-doors and vice versa last autumn, and have taken good crops of fruit from the trees this season. When moving the trees, keep as much soil as possible on the balls, and take care that the place is made ready before a tree is removed. Cover the roots up quickly and carefully, and they will commence action in a few days, and obtain hold of the new soil before all the leaves fall. In later houses, as soon as the fruit is gathered, lose no time in thinning-out superfluous shoots, so that the wood may thoroughly ripen. See that no trees are suffering from lack of water. I afford water to the trees as regularly, though not so frequently, through the winter as in the summer, and consequently suffer little from bud-dropping. Collect and tie in bundles all laths that have been used for propping up the fruit. Look over late trees on alternate days, and gather all the fruits that readily part from the trees. Houses containing fruits should be closed on cold nights, but all others should be fully ventilated.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Cauliflowers.—Plants still in the seed-beds if intended to be kept through the winter, should not suffer from crowding together, or they will not prove satisfactory. It is better to thin them out, pricking off the plants removed into other beds, or

where they can be covered with a frame or hand-glasses during the winter. Although protection is necessary in all but the most favoured districts, it should not be given until it is necessary, and air should always be afforded when there is no frost or rain. If cold frames are used, these should be sunk in the soil, so as to bring the plants up to the light. The time-honoured method of wintering Cauliflowers in hand-lights has not been excelled, although the ability to raise Cauliflowers in heat, by sowing the new early varieties has caused their disuse in many gardens. For the benefit of gardeners who may not have used hand-glasses or cloches, a few words of explanation may be necessary. The land—on a south border by preference, having been trenched after a heavy manuring, should be allowed to settle for a fortnight, and then be levelled, and made firm by tramping it evenly all over. It should then, on a dry day, be raked roughly, and lined out into beds 3 feet wide, with alleys between them of 2 feet in width. The hand-glasses (cloches), or hand-lights, measuring 2 feet square in the case of the latter, and 20 inches in diameter in that of the former, should then be arranged at a distance of 2 feet apart on the beds. The Cauliflower plants may then be planted in the space enclosed by each cloche or hand-light, at about 7 inches apart. In early April all but the four corner plants should be removed from each hand-light or cloche, and planted elsewhere. Air must be admitted whenever there is no hard frost by tilting the tops, or placing something under the rim; or in the case of hand-lights with removable tops, by tilting these or twisting them round a little, so as to admit the air. Cauliflowers now turning-in should be examined at short intervals of time, breaking down a leaf or two over the curd, which will generally be sufficient to protect them from injury. If too many are coming on at one time, pull some of them up by the roots when the heads are of sufficient size, and lay them in soil in a cool shed.

Outdoor Tomatoes.—Fruits not yet ripe on plants out-of-doors are not now likely to ripen outside, unless the plants are protected by spare lights or in other ways. In the case of plants in the open quarters, the stems may be carefully bent low down, and cold frames put over them, and by this means a quantity of fruit ripened off that would otherwise be lost. Fruits with a trace of colour in them may be cut, and hung up in a pit having a temperature of 50°, or the stems may be stripped of the leaves, and hung up indoors with the fruits attached, in order to ripen. All the plants in pots at present out-of-doors, for providing winter Tomatoes, must be placed in glass-houses forthwith.

Parsley.—Remove yellowing leaves, and stir the soil between the rows. A lot of the latest-sown Parsley plants may now be pricked out in cold frames, so as to make sure of having nice fresh healthy leaves in the early spring-time, when Parsley is, as a rule, very scarce on the out-of-doors beds.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Preparing Ground for New Plantations of Young Trees and Bushes.—Where the making of fresh plantations of fruit-trees and bushes is contemplated, a suitable site should be decided upon, and the ground selected afforded a good dressing of manure, which may be trenched in a few weeks before planting takes place. The trenching should be done from 1½ to 2½ feet, according to the natural depth of good soil. The soil at the bottom of the trenches should be loosened with a fork or pick, levelling the same in doing so in order to secure a uniform depth of earth. Place a good coating of manure over the loosed subsoil, following this with the top-spit, then another layer of manure and another spit of mould, together with the shovellings of the remaining good soil. In this way, ordinarily shallow soils may be increased to a good depth in the course of a few years, with satisfactory results.

Root-pruning.—Any bush or standard tree which has not yielded good crops of sightly fruit, should be root-pruned forthwith, so that fresh fibrous-roots may be made before the fall of the leaf. Dig a trench from 18 inches to 2 feet from the stem, according to size of the tree, and cut all roots clean off in the process of opening the trench, working the soil away from any tap-roots that may exist, in order to cut them off. This amputation of unnecessarily strong and damaged roots will induce numerous small feeders to push forth to the permanent advantage of

the individual trees operated on. Refill the trenches with some loamy soil, assuming the natural mould to lack fertility. If this is not at hand, a little short-manure should be added to the excavated soil before returning it to the trenches. In the case of wall-trees, or trees growing in cultivated parts of the kitchen garden—that is, fruit-plots in which vegetables are grown among the trees—a mulch should be laid over the roots, extending from the stems to 1 foot beyond the loosened soil, to prevent frost penetrating the roots, and to maintain the soil warm and moist.

PLANTS UNDER GLASS.

By G. H. MARCOCK, Gardener, Laton Hoo Park, Luton.

Gardenias.—Any of these plants which have filled their pots with roots should receive copious supplies of clean water and clear soot-water, and occasionally a slight sprinkling on the surface of an artificial manure. It is, however, advisable not to afford stimulating food to any of the plants which may have set flower-buds, or many of these will drop off. Overhead-syringing must not be done heavily at this season, and only in the morning when the day promises to be fine. The leaves of the plants should always be dry when night sets in. Gardenias require to be kept scrupulously clean, which state is best attained by sponging and dipping them, and occasionally syringing the leaves with soot-water; the soot for this purpose, about one peck, being put into a canvas bag, and immersed in a vessel containing 20 gallons of rain water. This soot-water should be made lukewarm at this season. The temperature for Gardenias may range from 60° by night to 65° to 70° by day.

Bulbs.—Quantities of bulbs in sufficient number to meet the requirements of the establishment may be potted, and afterwards treated in the manner previously advised. *Lilium longiflorum* var. *Harriisi*, if required in flower in the early spring, should be amongst those potted at about this date, using for it a compost consisting of friable loam of good quality, decayed leaf-mould, a small quantity of charcoal, and sharp sand in quantity sufficient to give porosity. A suitable size of pot is the small 32.

Fuchsias.—Cuttings of these plants may still be struck by placing them to the number of five or six in 48's filled with a rich, sandy compost. When rooted, pot them off, and keep them growing in an intermediate-house all through the winter.

Solanum capsicastrum.—Plants growing in the open air may now be potted in 48's and 32's according to size, and be kept shaded for a fortnight. Weather permitting, they may be syringed daily once or twice. The northern side of a cool house suits the plant whilst being re-established.

Salvia splendens, &c.—These plants now require plenty of water at the root, and any that have been in pots all through the season will be benefited by a liberal top-dressing of decayed manure; the variety compacta, as its name implies, is of a bushy and compact habit; and grandiflora is a graceful variety, with long pendulous spikes of bright scarlet flowers. The branches of *Salvia azurea* should be secured to thin sticks. The plant lasts in bloom for many weeks from November onwards, and is a pleasing-looking plant in the greenhouse. The bottom blooms as they get past their best should be pinched off, otherwise decay will spread to the others, even to those not expanded. Afford liquid manure-water occasionally till the flowers commence to open, when clean rain-water only should be supplied.

General Work.—Proceed with the housing of all tender plants, the low temperatures and moisture in the air, now, being unfavourable to them, even should no frosts occur. Water should be withheld from *Hippeastrums*, *Achimenes*, and *Gloxinias*, and the pots containing them placed one above the other on their sides on a dry shelf. The seedlings of herbaceous *Calecolarias* and of *Humea elegans* should, before crowding takes place in the seed-pans, be pricked off into others, and afforded a place on a shelf near the glass, and be guarded against slugs. A similar place should be found for double-flowered *Primulas*; and when watering the latter, do not allow it to lodge in the centres of the plants, or damping-off may result. Gradually reduce the quantity of water afforded *Caladiums*, and when the foliage has died off naturally, the same kind of treatment as that given to *Amaryllis* will suit them—with this difference, that the dormant tubers require stove-heat to keep them from decay.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

THURSDAY, SEPT. 30 { Show of British-grown Fruit by the Royal Horticultural Society at the Crystal Palace (three days).

SALES.

MONDAY, SEPT. 27 { Bulbs at Protheroe & Morris Rooms.

TUESDAY, SEPT. 28 { Bulbs, Continental Plants, Roses, &c., at Protheroe & Morris' Rooms.
Annual sale of Conifers, &c., at the Wood Lane Nurseries, Isleworth, by Protheroe & Morris.

WEDNESDAY, SEPT. 29 { Bulbs at Protheroe & Morris' Rooms.

THURSDAY, SEPT. 30 { Bulbs, Roses, Carnations, Hardy Plants, at Protheroe & Morris' Rooms.

FRIDAY, OCT. 1 { Orchids and Bulbs, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—55.2°.

ACTUAL TEMPERATURES:—

LONDON.—September 22: Max., 60°; Min., 51°.

PROVINCES.—September 22: Max., 60°, at Dungen Min., 48°, at Stornoway.

We are indebted to Professor G. HENSLOW for the following remarks on a most important and interesting subject. MR. FRANCIS GALTON has lately contributed a paper to *The Proceedings of the Royal Society* (vol. lxi., p. 401), on "The Average Contribution of each of several Ancestors to the total Heritage of the Offspring," wherein he illustrates and demonstrates the truth of a Law of Heredity, which he had previously stated as probable (*Natural Inheritance*, 1889, p. 134), "because it was then unsupported by sufficient evidence." Thanks to the late Sir EVERETT MILLAIS, who bred basset-hounds for many years, Mr. GALTON has secured sufficient facts to test the accuracy of the law, so far as it applied to the colours of the hounds. The law is, that "the two parents contribute between them on the average one-half, or (0.5) of the total heritage of the offspring; the four grandparents, one-quarter, or (0.5)²; the eight great-grandparents, one-eighth, or (0.5)³; and so on."

He observes that this law is in harmony with the observed facts of embryology, in which there are "binary subdivisions of the germ-cells, with the concomitant extrusion and loss of one-half of the several contributions from each of the two parents to the germ-cell of the offspring;" so that each parent contributing one-fourth is what might on *a priori* grounds be expected to be the case.

The bassets are dwarf blood-hounds, having two recognised varieties of colour, viz., white, with large blotches ranging between red and yellow. This kind is called "Lemon and White," the other has some black in addition, and is called "Tricolor." Mr. GALTON enters them as "T." (tricolor), and "N." (non-t.). Sir E. MILLAIS supplied Mr. GALTON with pedigree records of colours in 817 cases. The colours of all four grandparents were also known in 567. Of 188, the colours of eight great-grandparents were also recorded. Such were the bases for Mr. GALTON's calculations.

His first inquiry was to see if either sex was prepotent, and he came to the conclusion that the dam was prepotent over the sire in transmitting the same colour in the proportion of 6

to 5. The author, however, has accidentally reversed the entries "Sire T., Dam N.," and "Dam T., Sire N.," for his numbers, so that it is not the dam, but the sire which is really prepotent to this small amount. This difference does not affect the law, therefore, sex is not recognised in the calculations.

The problem is to show that if the fractions of the series given above be assumed to represent the contributions of each generation, respectively; then the law will be true if the calculated results correspond with the actual numbers of T. or N. offspring which were born.

Mr. GALTON's first table sets out the actual numbers as received from Sir E. MILLAIS of T. or N. offspring, corresponding to the four combinations of pairs of parents, viz., sire T. and dam T., sire T. and dam N., sire N. and dam T., sire N. and dam N. These are again taken with various combinations of grandparents.

From the table of data he deduced five other tables to illustrate various facts, and in the fifth and sixth puts side by side the calculated total tricolor offspring, supposing the law to be right, and the actual number of tricolor offspring recorded in the first table. The calculations are too elaborate to be reproduced here; all that need be said is, that the "co-efficient" or fraction to be multiplied into the total number of offspring (i.e. both T. and N. together) under each group of ancestry is calculated for each grandparent and great-grandparent or further ancestry, as representing the amount of inheritance supplied by each member of the ancestry. Thus in one case the total number of offspring observed was 118 (T. and N.). By multiplying this by .8342 or by .83 the result is the calculated number of T. offspring which ought to have been born, or 99. The observed or actual number was 100. The reader will also gather how accurate the law is by the following pairs of numbers representing the calculated and observed or actual numbers of T. offspring; when the calculated did not transcend grandparents the numbers were 236, 239; 149, 139; 6, 9; or grand totals 391, 387. Again in table 6, in which pedigrees were utilised up to the 3rd generation, we find the numbers as follows:—53, 56; 52, 56; 9, 9; 8, 6; 49, 46; 9, 8; and grand totals, 180, 181. Nothing could show better the truth of the law than the extraordinary accuracy of the last pair of numbers. Whether this law holds good for all other "elements of heredity," as we might call them, besides the single one of colour, is at present undetermined.

If we now turn to plant-breeding, of course we have no data wherewith to test the law, and it may be questioned whether any really practical value can be attached to it. The belief that the male is more usually prepotent in plants, has perhaps been generally acted upon; for it is a custom, I believe, to take pollen from a good parent for fertilisation, when some special strain is required.

Mathematical calculations, as a rule, are inapplicable to living organisms; partly because the latter differ in very many particulars, and partly because those particulars are correlated together in ways that are imperfectly understood. Hence, though Mr. GALTON successfully proves the law for a single, simple feature, namely for colour, in an otherwise pure strain of animals, it does not follow that the law can be applied with equal success to the ordinary problems of horticulture. Moreover, a new class of questions enters largely into these, which relate to hybridity. Here two

organisms, having different forms of stability, concur in producing a third form, which has a third form of stability. Mr. GALTON has himself discussed this subject in his *Natural Inheritance*.

Hence, if we test the law with multifold crossings in plants, we do not find it so readily traceable in the features of a single offspring, as he did in the number of offspring of the same colour.

First consider a single species, say the Fox-glove. All individuals (apart from the usual "individual" and trivial differences) are practically exactly alike. The law may be present, but it cannot be detected; the result is the same as if each parent contributed one-half.

In the case of first hybrids, though each parent may contain the sum of its ancestral series of precisely similar beings, yet the result, as seen in the structure and form, &c., of the hybrid offspring is not always equal to one-half—though reciprocal hybrids are mostly alike—for it often happens that the features of one of the parents predominate, though no universal rule exists as to any regular prepotency in either sex. Again, in comparing the visible features of hybrids with those of their parents, it is impossible to estimate the relative contributions, mathematically; for a part of a flower, for example, of the hybrid offspring may resemble the same part in one parent, while another part of the flower will be like that of the other parent. Thus, when *Rhododendron jasminiflorum* (with a white, long-tubed, small-limbed corolla) was crossed with *R. javanicum* (having a short-tubed, broad-limbed, orange-coloured corolla), the offspring, "Princess Royal," shows a broad limb, a long-tube corolla, and the orange-tint has not been contributed at all, the colour being rose-pink.

With regard to colours, it often happens that several offspring from the same pod will vary greatly in colour. Thus, when *Rhododendron Lobbi* (crimson) was crossed with *R. Brookeanum* (straw-coloured), the offspring were crimson-scarlet, red-orange, and primrose-yellow, varying to pale salmon.*

Hence the parental colours, which ought theoretically to have been representable by $\frac{1}{2}$, cannot be so represented if there are various colours, or various depths in the tint, if the colour be the same, as is often the case.

When a cross is recrossed to its third, fourth, or a later generation, as is frequently done among florists' flowers, though a calculation as to the relative amounts of inheritance which should be contributed by each member of the ancestry respectively, can readily be made, yet the visible results do not appear to correspond with them. Thus, to take an example, the hybrid *Rhododendron* "Little Beauty" contains five species. Its pedigree is as follows:—*R. jas.* × *R. jav.* (= *Pr. Rl.*); *Pr. Rl.* × *R. jas.* (= *Princess Alexandra*); *Pr. Al.* × *Duchess of Edinburgh* (= *R. Lobbi* × *R. Brook*; *Monarch*); *Mon.* × *R. Malayanum* = *Little Beauty*. Altogether there are here five generations, so that the amount of heritage contributed by each species would, according to Mr. GALTON's law, be approximately—

Jas., $\frac{1}{32}$; *Jav.*, $\frac{1}{64}$; *Lob.*, $\frac{1}{32}$; *Brook*, $\frac{1}{32}$; *Mal.*, and its ancestry, $\frac{1}{2}$.

Now, when we examine the visible results, we find that "Little Beauty" is almost identically the same as *R. Malayanum*. The colour

* "Hybrid *Rhododendrons*," by Rev. G. HENSLOW, *Journ. Hort. Soc.*, xiii., p. 30.

FIG. 64.—VIEW OF THE ROCKERY IN SIR CHARLES ISHAM'S GARDEN, LAMPFORT HALL.
(Dimensions of structure Height, 24feet; length, 70 feet; and breadth, 47 feet. See p. 209.)

and form are the same, though the latter is a trifle larger in the hybrid. The leaf is slightly truncated, such being apparently the only feature visibly inherited from any one of the other species, viz., *R. jasminiflorum*.

This case illustrates another, and by no means uncommon fact, that if two species be crossed, and the female parent may bear offspring, there may be no trace whatever of the male parent, the female being absolutely prepotent. In these cases, therefore, the law would seem to fail; or at least it is not traceable in external appearances.

Again, if the anatomical structures of the two parents are at all markedly distinct, their corresponding differences may be detected in a state of combination by a microscopical examination of those of the hybrid, as Mr. MACFARLANE has so well shown. In the case of Mr. VEITCH's hybrid *Rhododendrons*, I compared in every possible way the tissues of the stems and leaves of the parents and first hybrids; and there was rarely any appreciable difference whatever in their anatomy. I thus obtained almost purely negative results. This appeared to be due to the fact that these species probably live under much the same external conditions, so that the texture of the vegetative organs are the same; so that while in Mr. MACFARLANE's case some rough application of the law might possibly be attempted, nothing would follow from the above species of *Rhododendron*.

Finally, the only practical deduction which strikes me at present is, that the oftener the offspring of hybrids be crossed with new forms, the retention of any particular feature is proportionally lessened, and is soon practically lost; though, how far it may be retained "in the blood," and re-appear by atavism, it is impossible to say. That each parent of a cross will necessarily contribute exactly one-quarter of any special feature in the offspring, does not appear to be sustained by facts.

Potato Disease in Ireland.

REPORTS have for some time past been current that, owing to long-continued bad weather, certain districts would be, and were being, overrun by the Potato disease. And it is reported that ruin stares in the face many an Irish cultivator, who has lost his Potato crop, and that assistance will have to be given in many instances to ward off starvation. Truly, this is a most unfortunate condition of things, and the prospect of extirpating the disease a very poor one, as it is but too likely that the small holder will gather up all the refuse he can, in order to make up a muck-heap for distributing over his small parcel of land when he can procure sets—for these sets will be furnished him goes almost without saying. Of course, there are Potatoes with a good reputation as disease-resisters, as well as many with a bad one; and to-day we give the names of three varieties sent us by a northern farmer, who speaks highly of them as offering the strongest amount of resistance to the blight. The names of these, are "Up-to-Date," a heavy cropper; "British Queen," a good second early; and "Challenger," a new Fife-shire production well spoken of, but comparatively dear, as the stock of it is at present small. Good friends to the cotter and crofter in the Sister Isle will be those who get him to thoroughly cleanse his land and burn all the refuse that can be consumed. Such advisers will also see to the purchase of the very best sets; and the

local "authority" will well supplement his labours by furnishing such cultural instruction as may be best suited for the poor, suffering tillers of the soil.

THE ROYAL HORTICULTURAL SOCIETY'S Show of British-grown Fruits will be held at the Crystal Palace, Sydenham, on Thursday, Friday, and Saturday next. A conference on "Progress" will be held on each of the three days, and papers read: that of Thursday being by Mr. G. BUNYARD, and entitled "Progress in Fruit Cultivation during the QUEEN'S Reign." That on the following day, by Mr. A. W. SUTTON, will deal with the progress in vegetable cultivation during the same period of time; and the paper to be read by Mr. J. ASSBEE on Saturday will illustrate the progress made in market gardening. In view of the moderate crops of hardy fruits this season, the exhibition may not be so large as last year, but there will surely be a good show. A cold luncheon for gardeners will be provided on Thursday, at which the Council, judges, and lecturers will be present. Other persons interested in the show may obtain tickets for same from the Secretary before the 29th inst.

ROYAL BOTANIC GARDEN, CALCUTTA.—The Report from the Curator, Lieut.-Colonel KING, of the Royal Botanic Garden, Calcutta, for the year 1896-97 is one of considerable disaster, the garden having suffered greatly from the drought, which followed that of the year 1895-96. Much useful work has, however, been done in the cultivation of economic plants, the investigation of the flora of British India, and the enrichment of the herbarium. A monograph has been published of the Indian species of *Bambusa* by Mr. J. SYKES GAMBLE.

POMOLOGICAL SOCIETY OF BOSKOOP, HOLLAND.—The Plant and Fruit Committee awarded at a recent meeting the following First-class Certificate: to *Glyceria spectabilis folia argentea variegata*, shown by Mr. K. WEZELENBURG, Hazerswoude, Holland; and to crosses of *Clematis integrifolia* and *C. viticella*; namely, *Königin Wilhelmina*, *Hortulanus Wilke*, *C. H. Joosten*, and *C. van Kleef*, shown by Mr. C. VAN KLEEF, Boskoop. Second-class Certificates were awarded to climbing *Rose Carmine Pillar*, and to *Daphne laureola folius atro-purpureus* shown by Mr. K. WEZELENBURG, Hazerswoude; and to crosses of *Clematis integrifolia* and *C. viticella*, namely, *Queen Victoria*, *President Carnot*, *C. de Vos*, *Félix Faure*, *President Cleveland*, *M. van Kleef*, *Kaiser Wilhelm*, *Wm. E. Gladstone*, *Prins Hendrik*, *Hortulanus Witte*; shown by Mr. C. VAN KLEEF, Boskoop. P. A. OTTOLANDER, chief Secretary of the Pomological Society, Boskoop.

THE ISLE OF WIGHT.—On Wednesday, Sept. 15, the East Cowes Horticultural Society held an exhibition of Tomatoes, followed by a discussion opened by Mr. C. MARTIN, Clarence House Gardens, on the best methods of cultivation, and the most suitable varieties for indoor and outdoor planting.

—The Isle of Wight Horticultural Improvement Association took their third and last outing for the season at Swanmore Park, Hants, on Sept. 16. The party was received by Mr. E. MOLYNEUX, and conducted over the kitchen, fruit, and flower-gardens, the vineries, stoves, &c.; and last, but not least, the *Chrysanthemums* were inspected. The sub-tropical bedding and the rock-garden were much admired. The colour of the Apples in the orchard was excellent. The effects of planting the trees on the surface, and of thinning the branches instead of too much shortening back or pruning, were noted. The *Chrysanthemums*, of course, were especially interesting, and much time was spent in observing the habit of growth, &c., of some of the newer varieties. The party returned to the garden Isle much interested by their visit to Swanmore, where they had been most kindly entertained both by the proprietor, Mr. MYERS, and his gardener and steward, Mr. E. MOLYNEUX.

FLOWERS IN SEASON.—From Messrs. TOWNSEND BROS., Bloxham, Oxon, we have received a few blooms of new varieties of decorative and single-flowered Dahlias. The best of the decorative varieties is *Monarch*, an intense crimson-coloured bloom of large size, and the habit is described as good. The others possess pretty tints in colour. *Favourite* is a single flower of much attraction, the white petals being margined with pure orange. *Speckled Gem*, also single-flowered, has petals of crimson and yellow, promiscuously associated, giving the blooms a much-speckled appearance.

THE HARVEST IN SCOTLAND.—The *Dundee Courier* of September 16 gives reports collected from farmers in every county of Scotland, regarding the yield of the season's harvest. These reports are all of a satisfactory character. The yield of Barley is described as much above the average, and the quality excellent. Wheat and Oats were also very good crops. Turnips promise to be an exceptionally heavy crop, though the yellow variety in some districts is suffering from want of moisture. Potatoes are not a heavy crop, and there is not much evidence of disease. Beans and Peas have turned out well.

TORQUAY AND DISTRICT GARDENERS' ASSOCIATION.—The programme has just been arranged for the ensuing winter session of this body of gardeners. The session will commence on September 25, with the Presidential address from Dr. I. Hamilton Ramsay, a staunch supporter of the Society. Among those who have promised to contribute papers during the winter are Mr. A. H. WHIFFLA, M.A., B.Sc., Staff instructor in science and agriculture to the Devon County Council; Mr. F. W. MEYER, landscape gardener to Messrs. R. VEITCH & SONS, Exeter; and Mr. GEORGE BEDFORD, Head-master of the Torquay School of Art.

A STRIPED GLOXINIA BLOOM.—That flowers of the *Gloxinia* show much variation in their markings is well-known, and many strains have a ring or margin of colour different to that of the corolla and are furnished with very beautiful forms of spotting on the lobes, and for some distance down in the tube. But less common is it to find a flower of this type with white, descending markings as observed in some species of *Convolvulus*, such as has been sent to us by Mr. BREWER, gardener at Oaklands, St. Albans, which is a variety worthy of perpetuation by leaf-cuttings.

SALVIA SPLENDENS VAR. GRANDIFLORA.—The brightest thing at the last meeting of the Royal Horticultural Society's meeting was undoubtedly the groups of the above plant from Mr. HUDSON, Gunnersbury House Gardens, and Mr. H. B. MAY, Edmonton. Most gardeners are acquainted with the type, which they value for its bright scarlet colour at this season, when so few flowers of that colour exist under glass; but few know anything of the *grandiflora* variety, which is a much showier plant, having longer flower-spikes, which being consequently heavier, they droop somewhat, giving to the plant more gracefulness than is possessed by the type. The plants shown by Mr. HUDSON were in 10 inch pots, and had stood out-of-doors the whole summer in a sunny part of the garden at Gunnersbury House, Acton. They are the produce of spring-struck cuttings, and were twice stopped—the second time being early in July.

THE BROWNING OF PLANTS.—The so-called browning of plants—*Brunissure* of the French—a mysterious fungous disease until recent years uninvestigated, and so far as our knowledge goes, not wide-spread in this country, but met with occasionally on the Vine and a few other plants, is prevalent on the following plants in France according to M. DEBRAY, and whose statements are quoted by M. E. ROZE in a communication on the subject sent to the *Journal de la Société Nationale d'Horticulture de France*, and inserted in last month's issue. Among others, the following genera and species were mentioned as those on which *Plasmiodiophora vitis* had been found, *Hepatica triloba*, *Cynoglossum*, *Omphalodes*, *Papaver bracteatum*, *Tradescantia virginica*,

top, through which to pass a piece of galvanised-iron wire strained tight from each end), if placed down each row, will keep the netting off the leaves, and allow of the fruit being picked without removing the net. I should like to advise the planting of a good stock of plants of *R. laciniatus* in all gardens, as Blackberries are palatable to most persons, and they are excellent mixed with Apples in tarts or puddings. With a few Apples added, they make a very toothsome preserve. *Geo. Woodgate, Rolleston Hall, Burton-on-Trent.* [We recently observed *R. laciniatus* fruiting very freely upon a slope in Messrs. Cannell's nursery at Eynsford. The fruits, unless quite ripe, are very hard, but when cooked they are described as delicious in tarts and as preserve. Ed.]

WASPS.—I noticed in last week's issue that at Normanton, Stamford, wasps are very numerous and troublesome. In this district I have not yet seen a young wasp this year. What can have become of the queens that were very numerous early in June? A similar circumstance happened some years since at Mereworth, but on that occasion I attributed the loss of the queens to an early spell of very warm weather being followed by a sudden change to very cold weather. That was, however, not the case this year. *H. Markham, Northdown, Margate.*

—Your correspondent, Mr. John Butler, in order to save his fruit, cannot do better than continue a search for the nests of the wasps, giving to the men employed in the search a bottle containing dissolved cyanide of potassium, with instructions to push a piece of cotton-wool soaked with the solution into the entrance of each nest that they find, and the effect will be at once to prevent the passage of wasps either in or out of the hole. Some few years ago when making alterations in a gentleman's pleasure-ground near Macclesfield, my assistance was solicited in eradicating what became quite a plague of wasps; and knowing that the *Gardeners' Directory* gave a recipe for the purpose I procured it, and soon destroyed upwards of fifty nests with the substance above-mentioned. The operator need have no fear as to its effects on the insects, the poison being of a most deadly kind; and I destroyed the nests at any hour of the day. *T. Reid, Wentworth Nurseries, Hexham.*

A GARDEN OF ASTERS.—A rather novel form of summer-bedding has been adopted this year at Cliveden, the residence of the Hon. W. W. Astor. Owing to the nature of certain requirements, it was necessary to retard the spring bedding-plants as much as possible, so as to obtain them in the best condition in June. After this time, the flower-garden would be little seen until September, owing to the absence of the family, and it was suggested by Mr. Wadde, the gardener, that the beds, which are large, and lie a considerable distance from the mansion, should be filled with annual Asters in distinct colours. To this end a quantity (about 30,000) was raised in frames, and as soon as large enough pricked off in borders in the open, and thence to the beds. These are now just at their best, and the great masses of soft colours are very effective. The long waved border under the terrace is filled in with lines of distinct colour, following the outline of the border, the plants average not more than 6 inches in height, and they are full of flower. The varieties used in this part are Snowball, dwarf lilac, white Bedder, light Blue, and *delicata*, and the angles at the back are filled in with a scarlet coloured variety, a thousand plants being used in each line. The larger beds are planted in pairs with one colour, viz. Peach Blossom; white changing to blue; white changing to rose; red and white striped; white bedder, and purple; while a large distinct circle is filled-in with crimson and white variety, having a blue centre. Very few stray colours were to be found, which testified to the purity of the strain of Asters used. *C. Herrin.* [What have declaimers of the "massing" system to say to this? Ed.]

ENGLISH AND GERMAN ASTER SEED.—The reference made in last week's issue to Aster seeds raised at home and in Germany induces me to say that I have this season been enabled, through the kindness of Mr. Cannell, who sent me small packets of ten varieties of his home-saved seed, and of Messrs. Dobbie & Sons, who gave me, for the same trial, both their home-saved and best German imported seeds, to test them fairly on a plot of ground at Surbiton, where the seeds were sown in April in small clumps. I sowed the German seeds in the centre of the border, and the Eynsford and Orpington

seeds at either end, labelling each, and found, when they bloomed, that the home grown Asters were absolutely as good as the German. *A. D.*

THE SOUTHERN COUNTIES CARNATION SOCIETY.—The letter that appeared in the *Gardeners' Chronicle* for September 18, p. 204, signed "An Old Florist," is neither just nor generous. He appears to entertain the idea that no one can do a kindly action without deriving some pecuniary benefit in doing so. Now it so happens that Mr. Wm. Garton, jun., is a very high-principled gentleman, respected and beloved by all who know him—a member of the well-known wealthy firm of Garton & Co., and a great and liberal patron of horticulture; but his chief hobby is the cultivation of the Carnation, which he is endeavouring to bring to the fore by promoting a society, offering handsome prizes, and presenting plants of the best sorts, to anyone who would like to join the society. Of course, it is perfectly ridiculous to imagine that Mr. Garton is desirous of getting any pecuniary benefit from the society, his only object being (a truly good and philanthropic one) to set it going; and that it will prove a success under such favourable auspices, there can be no doubt. I think "An Old Florist" should not have expressed himself in the way he has done, without any just foundation whatever; and if he has any right feeling, he ought to apologise for having done so. *W. H. Rogers, J.P.*

TROPICAL NYMPHÆAS IN THE OPEN AIR.—I have been successful in flowering *Nymphaea capensis*, *Nymphaea Devonensis*, and *Nymphaea cyanea* in the open air this summer, at the end of a stove-pit in the open air, where I had made a brick-tank about 6 feet square and 2 feet deep, in the bottom of which 6 inches of mud was placed, and the tank filled up with warm water. To keep the water warm, a small pipe was attached to the air-tap of the hot-water pipes in the pit, so that I was enabled to have a little warm water flowing constantly into the tank, and keep the water at about 70°. After the water had been in the tank about ten days, I sank a very small plant of *Nymphaea capensis* to the bottom, it being first planted in an Orchid-pan; in a few days the foliage had reached the surface of the water, and very shortly afterwards it began to show its flower-buds (this was the early part of June), and at the end of that month several fine flowers had opened, from which time till September 20 we have had from seven to ten fully-expanded flowers daily on this plant. Later in the summer I planted *Nymphaea Devonensis* and *Nymphaea cyanea*, which have flowered equally well; and all being well next summer, I intend to make a larger tank, and plant out other tropical species. *W. J. Townsend, Sandhurst Lodge, Wokingham, Berks.* [These plants are being cultivated in open-air tanks in many parts of the country. Ed.]

EARWIGS.—These creatures are, as every gardener knows, very destructive to Dahlias, Zinnias, Verbenas, &c.; but knowing their aversion to moisture, it occurred to me to thoroughly moisten these plants overhead every evening after dusk, and the results proved highly satisfactory, not a single plant so wetted being injured by them. This was discontinued after the plants were established and making rapid growth. *W. H. Aggett, 70, St. James' Road, Bermondsey, S.E.* [Were the earwigs not troublesome afterwards? Ed.]

A WARNING.—Several allotment holders at Kent House, Beckenham, have this season lost portions of their produce, and the police have failed to make any arrest. One allottee evidently intends taking the law into his own hands, for he has put up a board with the following notice—"The Lord Helps those who help themselves; but, the Lord help that man I catch helping himself to my Marrows." *M. Webster, Kelsey Park Gardens, Beckenham.*

DAHLIA FLAMBEAU AS A BEDDER.—This is a grand variety for bedding purposes; in fact, it possesses every good quality. The plant attains a height of about 3½ feet. In colour it is scarlet, of a beautiful shade; and the blooms stand well above the foliage. It is, perhaps, the earliest Dahlia to come into bloom. Three large beds are filled with it this season at Hampton Court, and the effect produced is brilliant in the extreme. *W. H. A.*

CRESTED BEGONIA BLOOMS.—I was much interested in the bloom of the single-flowered crested Begonia in last week's *Gardeners' Chronicle*, and send for your inspection a double form of Begonia, which, when more fully developed is capitally crested. The enclosed is a small bloom from a nearly exhausted plant. You will notice it

has a good firm upright stem. The better developed blooms showed the crested much better. *F. Goss.* [The bloom, an exceedingly double one of large size, was distinctly crested on many of its petals. Ed.]

CHRYSANTHEMUM LEAVES DISEASED.—Under this heading a reply is given to a correspondent at p. 208. I gather from the reply that the leaves referred to were largely devoid of chlorophyll, and yellow in colour. There are some varieties that seem to show this yellow colouration when outdoors, under the best culture. I have noted it in several fine collections. Looking over one the other day in company with an experienced grower, he remarks that some of his plants showed the same golden hue in the leaves, but he found, after housing, that the green colour all came back again. That is an interesting fact. Perhaps the leafage suffers from too low a temperature outdoors during the autumn nights, and prefers the warmth of a greenhouse. Perhaps the excess of strong sunlight to which subjected during the summer is detrimental; evidently, it is an interesting case in plant physiology. *A. D.*

MR. HARRISON WEIR'S GARDEN.—I am somewhat mystified by the curious letter of Mr. Thomas Fletcher, re my garden. I do not understand what his planting a Potato fifty years ago and daily digging it up has to do with my planting my garden, but I do believe that I clearly understand some of his remarks. Here is one: "The best man in the world is hampered if he can only get a flat field with a barbed-wire fence (what has the barbed-wire fence to do with it!); the place must be ready-made for him, the trees must be of good size, and he must succeed someone." In making my garden, I have not succeeded someone else; nor do I consider it needful for a garden to have trees of a good size, but trees are necessary for pleasure-grounds and shrubberies. A garden is cultivated, a shrubbery "well ordered." "Few gardens can be made in a life-time, and in any case, a good deal of knowledge is required. Very well! Then I have done something that only few can do, for "Weirlegh" at Brenchley, Kent, was a wheat-stubble when I bought it, and when I left, it was very favourably noticed by most of the "gardeners" press as something uncommon. It may perhaps come as a matter of surprise to Mr. Thomas Fletcher to learn that my garden seven years ago was an utter waste-piece of ground, and the part photographed was a rough patch of grass lying in a hollow below the road, and a place where much of the sweepings and refuse of the villa gardens was brought and shot into—in fact, what is often termed "a muck-heap." This is the part shown. Below this was a small space and five Oak trees (not in the photograph), then a mound made by the waste of a stone quarry called "tip" being shot there, and below it a flat piece of ground, and to this the public having access at all times, they had dug up and carried off every Fern or wild flower that existed there. The ground slopes towards the south-west, in some parts precipitately. And so unpromising was the place to do anything with, that it and the new house stood empty for five years, neither it nor the land having been occupied, or even the latter fenced-in. Such was what I had to deal with. Whether I have any of the knowledge that is required I do not pretend to say, but it will be at once seen that I have not succeeded anyone else, as Mr. Thomas Fletcher says, at least I ought to have done. He says further, that "neither Mr. Harrison Weir nor anyone else could have made such a place as is shown in the photograph, unless his predecessor had planted the trees, and Nature provided crooked places and big stones." As I have said, this part was a rubbishy place, and I made the twisting paths, banked it about, and the rocks were brought by cart from a neighbouring quarry, and placed by hand as shown. All the trees have been planted according to my directions, and after about six years' growth they have been photographed. There are more photographs taken of different parts of the garden, all of which show that every part differs much from the other, and is generally unseen when a bend or turn is made in the paths. As to the wild flowers and plants, they have all been brought to it. About 2 oz. of Primrose seed have been scattered, and *Digitalis*, Poppies, and many other seeds; also nearly 10,000 *Daffodils* have a home and resting-place about the banks, &c. Those who have seen the place as it now is, have been kind enough to tell me "they" thought it beautiful; and to me, of course, it is so. With all the rest that Mr. Thomas Fletcher has written as to what a garden should be, &c., I agree, as it is one of the principles on which my garden is planned. Mr. Thomas Fletcher, however, states that spaces are to be left

between the herbaceous plants for annuals and half-hardy plants. With these I will have nothing to do. There are no annuals or bi-annuals but the wild flowers—no others; all others are perennials, low, and tall-flowering plants, &c. He also says that, "Every day without exception there should be something of interest for all comers, and good flowers to be always available." This is much the case for many months in my garden; but I do not care much for outdoor flowers when the frost is about, the ground frozen, and the winds keen and cutting. At all other times let there be flowers, and those in plenty. As to the volunteered opinion of Mr. Thomas Fletcher that "A collection of fowls can be got together in a year," I beg entirely to differ with him—no; nor in twenty years. My fowls come of stocks that date back far beyond half-a-century. It takes a lifetime to breed a good and true strain of high-class poultry. In conclusion, allow me to tell Mr. Thomas Fletcher that my garden is my garden in all senses. It was no garden about six years ago. I bought the land for a garden, planned it, planted it, maintained it. "It is all mine, and I am proud of it." *Harrison Weir.*

THE LATE MR. J. COCKER.

In the last issue of this journal, the demise of Mr. J. Cocker, nurseryman, of Aberdeen, was briefly recorded; it was there stated he was at the time of his death the senior partner of the firm of Messrs. Jar, Cocker & Sons, nurserymen, of Aberdeen. He had taken no active part in the business for nearly two years owing to a paralytic seizure; and latterly he has been a sufferer from other maladies. The deceased served his apprenticeship as a gardener and nurseryman with his father, who had started the business that was afterwards so greatly developed; he then for some time served as a journeyman at Cloncaird Castle, Ayrshire, and subsequently he obtained a situation as gardener near Croydon, remaining there for several years. During this sojourn in the south, he was paying great attention to the nursery business as then carried on around London. About twenty-six years ago, he joined his father in the business which now bears their name; and ten years afterwards, on the death of his father, he took his three sons, James, William, and Alexander, into the business as partners. He made a special study of "Florists' Flowers," and in conjunction with others encouraged a taste for some species which were fast on the wane in the estimation of gardeners.

In the cultivation of the Pansy, Phlox, and Pentstemon, he took the lead, and was fortunate in being the raiser of the first blue show Pansy, "Sunny-park Rival," which still ranks as one of the best, if not the best of its class. He devoted attention to the very beautiful and useful bedding Pansies, the descendants of crosses of *Viola cornuta*, recognising their good qualities as bedders and continuous bloomers; although I cannot claim for him the honour of having done the most in this connection, which honour justly belongs to Mr. P. Grieve and the late J. Downie. He was a successful cultivator of Roses, and the firm, under his far-seeing guidance, began about sixteen years ago to make Rose-growing a specialty, and their name has since become a household word in this branch of the nursery business throughout the country.

Much to the surprise of his fellow nurserymen, the cold and apparently ungenial climate of Aberdeenshire was made to produce Roses as fine as any in Scotland, or, indeed, out of it.

The almost universal use, at that time, of the Manetti Rose as a stock did not meet with Mr. Cocker's approval, and at great expenditure of time and money, he set himself the task of discovering the best kind of stock for each section and variety of the Rose. And it was owing to the experience thus gained, combined with high cultivation, that Cocker's Roses took the leading prizes at most of the horticultural shows in Scotland, and at some continental ones likewise. Another branch with which the name of the deceased will long be identified, is the cultivation of and bringing into prominence many fine species of herbaceous perennials which for a long time had been ignored. His two sons, William and Alexander, will continue to carry on the business as heretofore. *C. S. France.*

SOCIETIES.

ROYAL HORTICULTURAL.

SEPTEMBER 21.—An ordinary meeting of the committee took place on Tuesday last in the Drill Hall, James Street, Westminster, when the display of exhibits was almost equal to the capacity of the building. Such an exhibition of Dahlias is seldom made under the auspices of this society. Nearly all the trade growers of the flower were represented by large collections of blooms, and several amateurs contributed equally imposing exhibits. Novelties were numerous, and these secured as many as sixteen Awards of Merit. The consideration of new Dahlias was the greater part of the work before the Floral Committee, and beyond these very few awards to new plants were made. There was an excellent display of Gladioli, several exhibits of Chrysanthemums, and an extensive show of Roses grown in the open at Waltham Cross. Before the Orchid Committee was an exceptionally interesting Vanda from Messrs. LINDEN, Brussels, and a few other novelties. The exhibits of fruit were uncommonly few.

THE LATE MR. JAMES COCKER

Floral Committee.

Present: W. Marshall, Esq., Chairman and Messrs. H. B. May, Chas. T. Drury, R. Dean, J. H. Fitt, Geo. Stevens, J. F. McLeod, J. Jennings, Thos. Peed, R. B. Lowe, Chas. Jeffries, J. D. Pawle, D. B. Crane, Ed. Beckett, Geo. Paul, J. W. Barr, and J. Fraser.

Groups of miscellaneous foliage plants were put up by Messrs. JNO. LAING & SONS, Forest Hill, London, S.E., and Messrs. J. PEED & SONS, Roupell Park Nurseries, Norwood Road, S.E. In the collection from the latter establishment were a few Caladiums, some well-coloured pretty Crotons, the handsomely marked stove-plant *Leea amabilis*, several ornamental varieties of *Begonia Rex* and plants of *Dracena Sanderiana* (Bronze Banksian Medal).

Messrs. LAING's exhibit was a larger one, and it contained a number of excellent Crotons of moderate size but rare in colour; also some varieties of Cordylines with coloured leaves, as Lord Wolseley, A. Laing, and others; Ferns, Caladiums, several Gloxinias, a number of plants of the pretty *Saxifraga sarmentosa tricolor superba*, &c. (Silver Banksian Medal).

An excellent display of cut Roses was shown by Messrs. W. PAUL & SONS, Waltham Cross Nurseries. Roses thus remain in season a considerable time after the first Chrysanthemums have been exhibited. Of Queen Mab, a new China Rose, of rich salmon-apricot colour, there were excellent sprays of bloom; and of Empress Alexandra of Russia, Medea, and others, many of which have already been Certificated. Old Roses, including H.P.'s, Teas, Noisettes, and China Roses, were shown in a large number of varieties,

some of the Teas including Marie Van Houtte, Sylph, and Niphetos, being very pretty in their autumn buds. The distinctly-coloured Noisettes, William Allen Richardson and Madame Pierre Cochet, &c., were well shown (Silver-gilt Banksian Medal).

An Award of Merit was recommended to Cordylina Russell, shown by Mr. J. Russell, Richmond. It has narrow leaves, dull brown in colour, with midrib of very dull yellow.

Mr. THOS. LOWTON, Faversham, was recommended an Award of Merit for a variety of *Primula obovata* with imbricated flowers. The peculiarity, however, needs further development to become effective.

From Messrs. ROBERT VITCH & SONS, Exeter, was shown a plant of *Fuchsia triphylla* (type), and several plants of *F. t. superba*, which has crimson flowers of much larger size.

Messrs. JAS. VITCH & SONS, Royal Exotic Nursery, Chelsea, exhibited three very ornamental grasses—*Gynurus argenteum*, with fine erect plumes of pale purple colour; *Molinia caerulea variegata*, similar to the type, except that the foliage is variegated; and *Apera arundinacea*, with slender, drooping flower-stems, 3 feet or more in length. The general appearance of the plant is most graceful, and would be especially suitable for planting in a basket (First class Certificate). A very ornamental Vine, with conspicuously-coloured foliage, was exhibited. A nice plant of *Retinospora obtusa sulphurea* was awarded a First-class Certificate.

Salvia splendens grandiflora was capitally exhibited by Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton. The plants formed a bright, almost dazzling group, and this was well margined by pretty varieties of *Adiantum cucullatum* (Silver Banksian Medal). Mr. J. Hudson, gr. to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, was awarded a Silver Floral Medal for an excellent group of the same *Salvia* in flower.

A number of diverse varieties of seedling Fuchsias was shown by Mr. P. FAY, Addington, West Malling, Kent. The plants had been raised from seed sown in gentle bottom-heat about the middle of February last. They were planted out in the open in May, and lifted and placed into pots during the last week in August. Some of them were 2 feet high, and as much through.

A magnificent collection of spikes of Gladioli was shown by Messrs. J. BARNELL & CO., Howe House Nurseries, Cambridge. About 120 spikes were included in this exhibit, and the whole of them represented fine varieties. Many new ones and some unnamed seedlings were staged, but it would be invidious to select any for special mention from such a collection; a Silver-gilt Flora Medal was awarded.

Messrs. WM. COTSWELL & CO., Highgate Nurseries, London, N., showed a few plants of *Cornatou*, Princess of Wales, a variety of the Malmesbury type, also a number of sprays of the dark purple-fruited *Phytolacca decandra*, flowers of *Aster acris*, &c.

Fine sprays of the new *Physalis Francheti* came from Messrs. H. CANNELL & SONS, Swanley, Kent, and from Messrs. F. SANDER & CO., St. Albans.

A capital group of Chrysanthemums of the variety Lady Mary Fitzwigram, a good white-flowered decorative Chrysanthemum, very free and suitable for market, was shown by Mr. G. WYTHES, gr. to Earl Percy, Syon House, Brentford. A few plants of *Lilium Harriett* in bloom, and plenty of decorative foliage plants, helped to make the group of pleasing effect. (Silver Flora Medal).

An exhibit of cut Chrysanthemums was staged by Mr. W. J. GODFREY, Exmouth Nurseries; and he had twelve large blooms of the yellow-flowered Japanese W.R. Prince, one of Mr. Godfrey's seedlings. Other varieties included Lady Esther Smith, Barbara Forbes, Milano, Miss Emily Silsbury, Miss Oxenham, Madame Gustave Henry, Lady Kennaway, &c. Naturally, some of the blooms were a little deficient in colour.

An Award of Merit was recommended to Japanese Chrysanthemum Mychett White. It is said to be a fine market variety, and flowers early. A dozen good blooms were shown by Mr. M. RUSSELL, Farnborough.

A group of Chrysanthemums in flower, with ornamental foliage plants interspersed, was shown by Mr. J. H. WITTY, Nunhead Cemetery, London, S.E. Most of the varieties included were of the early-flowering section (Silver Flora Medal).

Mr. E. F. SUCH, of Maidenhead, had a group of cut flowers in bunches of early Chrysanthemums cut from out-of-doors. Of the numerous varieties, the following were best:—Harvest Home, Eulalie Morel, pink; M. C. Desgranges, Long-fellow, white, an excellent variety for cutting from; Madame Carniflage, white, petals long and drooping; Pieroy's Seedling, Mdle. M. Massey, and Blushing Bride (Bronze Banksian Medal).

A very fine show of hardy flowers was made by Messrs. PAUL & SONS, Old Nurseries, Cheshunt, obtaining the award of a Silver Flora Medal. The better things were new Phloxes, apparently of continental origin, viz., Miss Pemberton, cherry red, with flowers 1½ inch across—very showy (Award of Merit); Ferdinand Cortez, a magenta-coloured variety; Joseph Burton, one of a rosy-crimson colour, also very nice; Coquillet, a bright looking scarlet flower, of large size; Jav. nase, a lilac and white flower; Eclairer, a purplish-crimson-coloured flower; Regulus, a soft pink-flowered variety; and Fantome, a flower of lilac and white. Other flowers in fine condition were *Aster* (perennial) *Novae Angliae* var. *pulchella*, deep purple; *A. Novae Belgii* var. *lurida*, and *A. N. B. levigatus*, of rosy-lilac colour; *Funkia subcordata grandiflora*, which differs from the type in having large flowers; *Aster Bessarabicus*, with capitally-developed

broad-petalled reflexed flower; and W. R. Prince, a large, reflexed Japanese, with the deep colour of Sunflower, but darker, and broader in the petals; this is a very promising variety, and the committee expressed a wish to see it again. A small Silver Medal was awarded to Mr. GORREY for his collection of blooms.

A meeting of the general committee took place at Anderson's Hotel on the 20th inst., Mr. T. W. Sanders presiding. The secretary presented a report of the medals awarded to miscellaneous exhibits at the recent show; and also reported the financial position as satisfactory, members' subscriptions coming in well. A sub-committee was appointed to make the preliminary arrangements for the annual dinner in November. Twelve candidates for membership were elected, and the North Canterbury (New Zealand) Chrysanthemum Club was admitted to affiliation.

THE BRITISH MYCOLOGICAL.

The first "Annual Week of Fungus Foray" of this Society was held in Sherwood Forest from 13 to 18 September, 1897. As the Society was only founded last year, some little curiosity was felt as to how it would carry out its proposed scheme of working the mycologic flora of Sherwood Forest. Devotees appeared in Workshop from the north, from the south, from the east, and from the west of England in good numbers, and during the week excursions were made in various directions from this centre.

The present writer has taken part in many fungus forays; he has seen one generation of mycologists pass quite away and join the majority, while many others have dropped from the ranks of the working fungologist incapacitated either by illness or by age, old friends and old faces have gone and are missed, but it is a pleasant thing to see a new generation, brimful of youth and overflowing with enthusiasm, plunging into the study with that keen zeal which is so essential to those who would master the hymenomyces. Circumstances prevented the writer from hearing the presidential address of Mr. G. Massee, on "Mycological Progress during the past Sixty Years," but it would, without doubt, be appropriate and eloquent, coming from the distinguished author of the *British Fungus Flora*. The Society is fortunate not only in its president but even more so in its Secretary, Mr. Carleton Rea, whose great practical knowledge of fungi on the one hand, and his power of managing men on the other, combined with an enormous capability for work, make him an ideal secretary for such a society. This is not the place in which to enumerate all the rare species found during the week, but some must be mentioned. *Sparassia crispata* was sent to the meeting from Surrey; *Agaricus decemcostatus* was found during one of the excursions, an interesting plant, with which we are all familiar, from Fries' figure in *The Lilies*, but which looks something like a cespitose form of *A. nebularis*. *Amanita recutita*, a fungus which Fries recognized as a British species from Berkeley's figure in *The Outlines*, t. 3, f. 8, under the name of *Ag. excolaus*, was found in Clumber Park, as well as *Nolanea chloropollus*, growing in short grass by the roadside. Not far from the last-mentioned, on the perpendicular side of a road-drain, several specimens of *Clitocybe incilis* were gathered, a plant by no means common.

At the evening meeting, Mr. A. CLARKE read a paper on "Photography as applied to Mycology," illustrated by numerous photographs of various species of fungi. This was heard with interest by all present, for all had more or less practical acquaintance with the difficulty of making the pencil depict just what one wants to show. Dr. Plowright gave a short résumé of the new species of Uredines and Ustilagines found during the past year, and exhibited specimens of *Urocystis filipendulae*, Tul., from Mr. Tatum, of Salisbury. Specimens of the two species of *Barley-smut*, *U. Hordei* and *Jensenii* were also shown.

The visit to Birklands on the following day was especially interesting. This is one of the oldest parts of the forest. Beech and Oak are the predominating trees. The Oaks, to which the attention of the mycologists was more particularly directed, were, of course, the oldest and most decayed. Here they were to be seen in hundreds in various stages of hollowness and decay. Twenty years ago one would have passed them by as being merely instances of hollow trees; for why should a tree not become hollow when it is old? Since the masterly researches of Hartig, however, upon the diseases of timber, this is quite changed, and we now ask ourselves what fungus is it that has hollowed these trees? The bulk of the members blessed with youthful eyesight and youthful legs, under the care of a stalwart forester, strode off at the rate of 4 miles an hour, leaving three or four of the less athletic to amuse themselves by turning over fallen logs, dead branches, and decayed leaves, in search of the "microscopic." We did not cover above a quarter of a mile of woodland all day, but the treasures we did find made amends for our deficiency in walking power. Again and again, did we gaze at the stricken Oaks as we wandered under them, examining their fallen limbs; a few bore specimens of *Fistulina hepatica*, but this was not the destructive agent. The manner in which these Oaks grew, or rather how they had ceased to grow, was striking. They had almost without exception well-grown trunks of pretty uniform diameter, up to 30 or 40 feet; then the trunk rapidly diminished in a spindle-like manner, and in almost every case the top of the tree had been broken off by the wind. This destruction of the upper branches was so uniform and so characteristic that it could not fail to attract attention. There were some

hundreds of trees all growing under the same conditions, and exposed to the same winds, &c., none had their large lateral branches blown off, none had been uprooted; something must therefore have predisposed their upper branches to injury. We find as a general rule that the nature of the particular injury a strong wind does to trees, is determined by pre-existing fungoid disease present on them. These grand old Sherwood Oaks, if they were not all hollow, were dead and rotten within; the heart wood being reduced to a mass of delignified tissue. This was shown when some small animal, such as a squirrel or even a mouse, had made its hole through the bark and still living sapwood, as soon as the burrow reached the dead-heart wood, it ran out like sand into a heap beneath the hole, only it was not in fine powder like sand, but in the form of reddish-brown, dry, cuboid fragments. Now, this cuboid fracture depends upon the way in which the mycelium of the fungus originally extended itself, and is beautifully shown in Hartig's *Lehrbuch der Baumkrankheiten*, taf. v. i., figs. 1, 2, and 3. The writer examined tree after tree for parasitic fungi; not a single specimen of *Polyporus dryadeus*, which is so common in Herefordshire, nor of *P. quercinus*, nor of *P. fomentarius*, nor *Agaricus melleus* was seen all day. There was one beautiful *Polyporus*, however, growing in grand luxuriance on great numbers of the trees, and that was *P. sulphureus*. This we know to be one of the worst enemies the Oak-tree has in the fungus kingdom. But we must stop; if we get upon the question of fungus disease, we are apt to grow wearisome to our best friends, and the Editor will remind us that the available space of the *Gardener's Chronicle* is not unlimited.

What became of the walking-party, where they went, and what they found, is not known to the undersigned; but, doubtless, they enjoyed the ramble through the classic glades of the forest of Robin Hood. Amongst those who took part in the meeting, &c., were Miss Rose, of Worcester; Mr. J. Rose, President of the Worcestershire Naturalist's Club; Prof. J. W. Carr, Miss C. Crossland, Sutcliffe; C. T. M. Plowright, J. Needham, Salmon, and H. G. Peacock. *Charles B. Plowright, M.D., King's Lynn, September 18, 1897.*

ONION SHOW AT BANBURY.

THIS Oxfordshire town continues to have its annual display of Onions, owing to Mr. HENRY DEVERILL's prizes that he offers for specimens of pedigree bulbs he has put into commerce. The show is arranged in his shop and premises, which have recently undergone considerable enlargement. As soon as the judging is over the townspeople are admitted, and they crowd the place all the time it is open to them.

The timepiece offered for the six largest and handsomest specimens of either of Deverill's Pedigree Onions was won by Mr. J. BOWERMAN, The Gardens, Hackwood Park, Basingstoke, with six solid, symmetrical, and handsome specimens, weighing 14½ lb.; but they did not reach the record weight of 1895, namely 17 lb. The twelve best specimens of Deverill's Ailsa Craig or Cocoa-nut came also from Mr. BOWERMAN, and they scaled 26 lb. Cocoa-nut was finely shown in this class, but it has no chance against Ailsa Craig, which comes so much larger.

The best twelve specimens of Deverill's Anglo-Spanish, Lord Keeper, Royal Jubilee, and Rousham Park, were the latter, from Mr. W. KEPP, The Gardens, Faringdon House, Faringdon, weighing 3½ lb.; Mr. R. LYE, The Gardens, Sydmonton Court, Newbury, was 2nd, with Anglo-Spanish, weight 1½ lb.

The best twelve of Improved Wroxtton, a long Globe-shaped variety, which has the reputation of being a good keeper, came from Mr. J. E. THOMAS, Oxford; they were admirable illustrations of the type, and weighed 1½ lb. Mr. R. LYE was 2nd with well-formed bulbs of lighter weight.

Deverill's Challenge is a new and distinct Onion, with a pink skin, flat in shape, and quite solid. Mr. LYE had the best twelve, Mr. WAITE taking the 2nd prize.

The largest and handsomest specimen of any one of the Pedigree Onions was one of Ailsa Craig, from Mr. BOWERMAN, who was 1st with a fine, solid example; Mr. KNELLER came next with an Anglo-Spanish.

In the class for the best twelve of any one of the Pedigree Onions, open only to *bond fide* amateurs and cottagers, there were twenty-four entries; the best twelve were Ailsa Craig, from Mr. H. ELLMER, Cuckfield, weighing 18½ lb., the 2nd prize went to Mr. W. WOODCROFT, Nelthrop, Banbury, with the same variety, weighing 14½ lb. Five other prizes were awarded, and in each case were won by Ailsa Craig.

The best six of Deverill's Oxonian Leek came from Mr. R. LYE, superb specimens; Mr. BOWERMAN came 2nd, and Mr. KNELLER 3rd.

The best collection of eight distinct kinds of vegetables comprising Deverill's specialties, came from Mr. R. LYE; he had superb Oxonian Leeks, Aylesbury Prize Red Celery, and Exhibition Scarlet Intermediate Carrot, with others; and Mr. C. J. WAITE came 2nd.

ENGLISH VARIETIES OF POTATOS IN THE U.S.A.—In many of the American horticultural journals notices are found of the trials of English Potatoes, and in the opinion of the writers these varieties are pronounced to be unsuited to the climate of the U.S.A., excepting in seasons whose climatic character approaches that of this country. The only variety

which seems to have exhibited anything like its true character under skilled cultivation is, as we learn from *American Gardening*, Myatt's Ashleaf.

MARKETS.

COVENT GARDEN, SEPTEMBER 23.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

POTATOS.

Arrivals have been rather heavier the last few days; trade firm for choicest samples, but other descriptions have fallen about 5s. Present quotations:—Hebrons and Snowdrops, 70s. to 85s.; Giants and Magnums, 65s. to 75s.; Blacklands, 55s. to 62s. 6d.—John Bath, 82 and 84, Wellington Street Covent Garden, W.C.

SEEDS.

LONDON: Sept. 15.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maize Pond, Borough, London, S.E., write that although it is rather late, sowing orders for Trifolium still drop in; as regards stocks of this article, the platter this season will prove quite bare. For Mustard and Rapeseed, the sale is slow on former terms. Winter Tares meet just now with only a meagre inquiry. There is no change in Rye. Peas, Haricots, and White Runners tend upwards. Bird-seeds are steady in value, but quiet in demand. The Linseed market is flat.

(Markets carried over to p. ix.)

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending September 18, is furnished from the Meteorological Office:—

"The weather was fine and dry generally during the earlier half of the week, although a good deal of cloud prevailed at times, and some slight showers occurred in the extreme north and north-east. By Thursday, however, unsettled, rainy conditions had commenced to spread slowly over us from the northward, and by the close of the period the change had extended to all parts of the kingdom.

"The temperature was again below the mean in most districts, but was rather above the normal in 'Scotland, N. and E.,' and just equal to it in 'Scotland, W.' and 'Ireland, N.' The highest of the maxima were recorded on the 13th, and ranged from 75° in 'Scotland, E.,' and from 72° in 'Scotland, N. and W.,' and 'England, S.W.,' to 67° in 'England, E. and N.W.,' and in the 'Channel Islands.' Towards the end of the week the daily maxima were very low. The lowest of the minima were registered either at the commencement or at the end of the period, and ranged from 33° in 'Scotland, W.,' and 34° in 'England, S.W.,' to 40° in 'England, S.,' and to 48° in the 'Channel Islands.'

"The rainfall was less than the mean, excepting in 'Scotland, N.' The deficit was very considerable in most districts, and especially in the west and south-west.

"The bright sunshine exceeded the mean in 'England, N.E. and S.W.,' as well as in 'Ireland, S.' and the 'Channel Islands;' in most other districts there was a deficiency. The percentage of the possible duration ranged from 53 in the 'Channel Islands,' 50 in 'England, S.W.,' and 48 in 'Ireland, S.,' to 25 in 'England, E.,' and 21 in 'Scotland, N.'"

ANTHRACITE COAL: *Anxious.* This is a very enduring kind of fuel. Much dearer than either coke or small coal; it is probably cheaper in the end than either, and a great saving in stoking. To burn it alone requires a strong draught during the early stages of combustion, after which a less strong draught is needed. To obtain the required strong draught, it is sometimes necessary to lengthen the chimney-stalk; and to preserve the fire-bars from destruction, the ash pit should be constructed to hold water. It would be false economy to use coke or ordinary coal with anthracite.

ARALIA SIEBOLDI, ABNORMAL LEAVES: *A. E. C.* The plants suffer from an over-luxuriance of growth, or, rather, of the mesophyll cells of some of the leaves, which stretch themselves out hose-like, forming swellings, and often causing a rupture of the epidermis. According to Sorauer, these appearances are met with in *Dracena*, *Cassia*, *Acacia*, *Aralia*, *Panax*, *Hedera*, *Camellia*, &c. Keep your plants in a lighter and drier house, affording them only a moderate quantity of water at the root, that is, let them get rather dry before applying water, and do not give manures of any sort. The causes of the malady have not been ascertained with certainty.

BOOKS: *T. Trillou.* You should enquire of Mr. Upcott Gill, the Bazaar office, 170, Strand, W.C.

CELERY BLIGHT: *C. W. D.* Celery-leaves seriously affected with a disease, have been forwarded to us, which threatens to destroy the whole Celery crop. At first, the leaves are mottled with roundish or oval, pale brown spots, dotted in the centre with small black points; later on, the spots and leaves are nearly wholly of one colour, densely sprinkled with little elevated black dots, or perithecia. These cells, or perithecia, contain long slender sporules about 30 to 35 millimetres long, and scarcely one millimetre in diameter, with very indistinct guttules or faint septae. Probably this is a variety of *Septoria petroselin*, but with more slender sporules. Of course, this is wholly an endophyte, and exists in the plant before it makes its appearance on the leaves, and hence is most difficult to deal with. Doubtless its spread may be checked by rooting up all hopelessly diseased plants, and picking the leaves off such as are not so bad. One of the copper solutions might be tried as a forlorn hope. *M. C. C.*

CLERODENDRONS: *J. G.* Disease, as shown on the leaves sent, often attacks *Clerodendrons* in the autumn. Keep the plants tolerably dry at the root for two or three months, then cut them back, shake out, and start again.

CORRECTION.—Mr. J. Anderson desires us to correct an error which he made in "Northern Orchid Committee" report (see p. 207). The *Lælia elegans* Cawenbergi, credited to H. Low & Co., Clapton, was the property of William Thomson, Esq., Walton Grange, Stone (gr., Mr. Stevens).

DISEASED CARNATION GRASS: *T. P. & J. F.* The pest is *Uromyces Dianthi*, Nsl., and as it is completely an endophyte—that is, it exists in the plant before signs of it appear on the surface—there is little hope of any application of fungicide solutions. Plants not attacked should be isolated, and syringed with Bordeaux Mixture. All injured plants and leaves should be burnt. *M. C. C.*

GENISTA OTTISUS: *J. G.* The cuttings should be inserted late in June, in pots of sandy peat, surfaced with silver-sand, well watered, and when the foliage has got dry, they should be covered with bell-glasses, and stood in a greenhouse, shading them from bright sunshine. The cuttings should be rooted in six weeks, when they may be potted off singly.

GINSENG: *N. B.* The root of a Chinese plant, *Panax quinquefolium*, said to possess extraordinary medicinal virtues. This plant is also found in North America, and does not possess any such virtues.

INSECT: *Colonel H. Oakden Fisher.* The epidermis is eaten away by the Pear-slugworm, *Selandria atra*. The worm is blackish or bottle-green, of a club-shape, and covered with slime exuding from the skin. Dusting the leaves with quick-lime

several times on successive days will clear them off the trees. Syringing with strong soap-suds or tobacco-water destroys them. The soil underneath the trees should be skimmed, removed, and charred or deeply burned.

INSECTS ON PALM ROOTS: *J. C.* The minute white creatures are apparently the young stage of some spring-tail insect (*Collembola*), but whether they do damage or not is difficult to say. The application of some approved insecticide might destroy them. *R. McL.*

NAME OF FRUIT: *F. F. F.* Apple Worcester Pearmain. Of the Fern, you must send a better specimen.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*J. Banks.* 1, Tarragon (*Artemisia dracunculua*); 2, Summer Savory (*Satureja hortensis*); 3, Wormwood (*Artemisia absinthium*); 4, Horehound (*Marrubium vulgare*); 5, Winter Savory (*Satureja montana*); 6, Sweet Basil (*Ocimum basilicum*); 7, Pot Marjoram (*Marjorana hortensis*).—*W. D. H.* 1, *Impatiens parviflora*; 2, *Mentha hirsuta*.—*Conifera.* 1, *Juniperus virginiana* var. *Schottii*; 2, *Quercus illex*; 3, *Juniperus virginiana*; 4, *Cryptomeria japonica*; 5, *Juniperus recurva*; 6, *Caprea macrocarpa*.—*F. Carter.* 1, no flowers sent; 2, *Thia orientalis*; 3, *Cryptomeria japonica*; 4, *Caprea pisifera*; 5, *Sequoia sempervirens*; 6, *Fitzroya taxagónica*.—*Z. Z.* 1, *Spiraea*: no flowers sent; 2, *S. canescens*; 3, *S. japonica* var.; 4, *Veronica* (garden hybrid); 5, *Viburnum*; 6, *Eleagnus*. Specimens very poor, scrappy and imperfect.—*J. Backhouse & Son.* *Podocarpus alpina*, and *Araucaria sericea* (*Physianthus albens*).—*J. G.* 1, *Linaria bipartita*; 2, *Retinospora pisifera aurea*; 3, *Juniperus excelsa*; 4, *Cyrtodella fulgida*; 5, *Aster besenarabicus*.—*H. W.* 1, *Abutilon Darwini* var. *sepiatum*; 2, *Abutilon striatum*; 3, *Eupatorium album*; 4, *Sempervivum arachnoideum*; 5, *Pachyphytum bracteatum*; 6, *Pachyphytum intermedium*; 7, *Haworthia margaritifera*; 8, *Crataegus Azarolus*; 9, *Asclepias curassavica*.—*Stanhopea.* You must send a better specimen, and when in flower if possible.—*Caldwell & Sons.* *Atriplex hortensis* var. *atrosanguinea*.—*G. P.* The purple-leaved plant is *Atriplex hortensis* var. *sanguinea*, the other is *Periploca græca*. The seeding of this plant is rare in this country.

PEAR: *A. R. S.* We must see the insect before we can name it; and none was sent. Kindly send specimens.

SOOT: *A. M.* Let a peck of fresh soot be put into a canvas bag, soak in 20 gallons of water for two or three days, and then use for the Cabbages, &c.

TOMATOS: *A. M.* The fruits crack owing to excess of moisture at the root.

WOODLICE IN CUCUMBER-HOUSE: *C. H. W.* Try the effect of pouring boiling water into all crevices, and dashing it under the beds and wherever there is a hiding-place for the insects; doing this at night when they are out of their haunts feeding. Slates laid on the floor about 1-inch above it form capital traps, and large numbers can be caught by this simple means. Carbolic acid might be tried with good effect.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardener's Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED,

and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

THE

Gardeners' Chronicle.

SATURDAY, OCTOBER 2, 1897.

THE HORTICULTURAL TRADE DURING THE PAST SIXTY YEARS.

IN looking back upon the horticultural events associated with the long reign of the Queen, some mention of the changes which have occurred in connection with the London and provincial seed and nursery trades during that period may not be without interest. As far as can be learned—for no attempt appears to have been made to compile anything like a reliable trade list until the late Mr. John Edwards started his *National Garden Almanac* in 1833—the leading wholesale seed houses in 1837, or within a year or two of that date, were J. G. Waite, Hatton Garden; J. Nutting, 46, Cheapside; Warner & Warner, 28, Cornhill; Noble & Co., 162, Fleet Street; and Flanagan & Son, Mansion House Street, though probably the latter was a retail rather than a wholesale dealer in seeds. I think it may be safely assumed that the firms of Minier, in the Strand; Beck & Co., Adelphi; and Wrench, London Bridge, were also in existence as wholesale seed dealers in 1837; for although their names may not have appeared in contemporary advertising records, it being a point of etiquette with some of the old firms not to advertise, and they were content to be represented on journey by the principals or their travellers; yet their existence is pretty certain.

In some of the gardening publications which appeared in 1843 could have been seen a notification by William Hurst and William George McMullen, "for many years past engaged in the house of Warner & Warner, 28, Cornhill," to the effect that it was their intention to open a new seed establishment at 6, Leadenhall Street. This announcement covered considerable space, as a catalogue of flower and vegetable seeds formed a good part of it; and from it could be learned that the Walcheren Broccoli had only recently been offered, and that Myatt's Victoria Rhubarb and British Queen Strawberry, also raised by Myatt, were new also, the latter being quoted at 10s. 6d. per hundred.

By 1853 changes had occurred, for Warner & Warner had disappeared; the firm of J. Nutting had become Nutting & Son, and was still in Cheapside, and the name of Lockhart, 84, Cheapside, also appears; J. G. Waite had gone to Holborn, and H. Clarke probably from the Borough to King Street, Covent Garden; and the firm of Noble & Co., perhaps the oldest of all, had become Noble, Cooper, & Bolton.

Of the foregoing houses, Nutting & Son

carried their business to Barbican, and subsequently to Southwark Street; it is one of the best known and best respected of the London wholesale seed-houses. Hurst & McMullen subsequently became Hurst & Son, and some years ago changed their head-quarters to 152, Houndsditch, where they carry on an enormous business, the present head of the firm being Mr. N. Sherwood, so well known for his great liberality to our gardening charities. Beck & Co. became Field & Child, and later as Beck, Henderson & Child, and at the time of the commencement of the Thames Embankment carried their business from the Adelphi to Upper Thames Street, and eventually became united with the firm of Waite & Co., who some years since changed from Holborn to Southwark Street. The firm of Minier, Nash & Nash, so long carried on at 60, Strand, was eventually absorbed by Waite & Co. Noble & Co., subsequently Noble, Cooper & Bolton, eventually R. Cooper, of Southwark Street, and now Cooper, Taber & Co., ultimately absorbed the firm of Waite & Co., and they are still in business in Southwark Street.

In 1853 Charlwood & Cummins, a business probably established before 1837, were at Tavistock Row, Covent Garden, where the firm remained for many years, and which at one time enjoyed a considerable reputation for tree and choice seeds, subsequently becoming Howcroft & Watkins, and who still carry on business in Hart Street, Covent Garden. In a trade list dated 1854, I find for the first time Batt, Rutley & Silverlock at 412, Strand, though the firm may have been founded some years previously, and it is now Rutley & Silverlock, of Savoy Street, Strand.

In 1853, the firm of G. Gibbs & Co. was in Down Street, Piccadilly, and that of T. Gibbs & Co. in Half Moon Street, Piccadilly, and both had doubtless existed or some years; but one firm only exists now—that of T. Gibbs & Co., Down Street, but it is doubtful if anyone of the name of Gibbs is now associated with it.

James Carter o doubt established himself in business in Holborn antecedent to the Queen's accession, as I have one of his catalogues bearing date 1842, a publication in remarkable contrast to that issued by Messrs. Carter & Co. in the present day. On the death of James Carter, Messrs. Ainsworth, Beale, & White—I believe, three of the assistants in the business—became partners, and subsequently it was in the hands of Mr. Beale alone. Eventually he took into partnership Mr. W. H. Dunnett, an extensive seed-grower at Dedham and St. Oystin, in Essex; the wholesale branch was added to the retail business, and it has now grown into a very large one. In 1858, Hooper & Co. were in the centre-row Covent Garden, and they subsequently went into the wholesale trade; but the name appears to have now become almost, or quite, extinct. The same may be said of Smithers & Crighton, who had a wholesale place of business in Bunhill Row, twenty years or so ago.

I think it must have been subsequent to the Queen's accession that Messrs. P. Lawson & Sons of Edinburgh, established themselves in Great George Street, Westminster, opening a London dépôt; they subsequently went to King Street, Cheapside, and eventually to Southwark Street; and it was while in occupation there that the London branch was given up. Messrs. Stuart & Co., now of Henrietta Street, Covent Garden, is a firm dating back about forty years or so. Mr. A. Legerton has been in business at Aldgate for many years. The youngest of the London wholesale seed firms is that of Watkins & Simpson, Exeter Street, Strand. Mr. Watkins began his business career with Messrs. Charlwood & Cummins, in Covent Garden, and subsequently had charge of the flower-seed department of Messrs. Hurst & Son, until he started in business as above, and is now at the head of a successful commercial undertaking. So much, then, for the wholesale trade firms so far as information

is available. I confess that the earlier information at my disposal is somewhat scanty, and is no doubt open to correction; much of it, however, is the outcome of personal knowledge, as I became connected with the London wholesale seed trade forty years ago.

In reference to the London retail seed and nursery businesses, I find that in 1844, W. Cattleugh was at Hans Place, Chelsea, also in the Old Brompton Road, and was then sending out the new *Pelargoniums* raised by Foster and others. It may, I think, be assumed that Gray, Adams & Hogg were in business at that time in South Kensington, on the site of the present Exhibition Road, but the firm had disappeared before 1851. Cutbush was at Highgate, Cuthbert at Southgate; J. Cuthill was in business at Denmark Hill, Camberwell, in 1837, and in 1842 he sent out his Black Spine Cucumber, which was a great favourite with gardeners for many years; Chandler & Sons were at Vauxhall when the Queen began her reign; Dennis in the King's Road, Chelsea, raising and sending out, among other things, *Pelargoniums* and *Calceolarias*; Little was carrying on a florist's business in the same road; and the premises after remaining unused for a number of years have been quite recently acquired by Messrs. Carter, Paterson & Co., carriers, &c. N. Gaines, a famous raiser and cultivator of *Pelargoniums*, was at Battersea; Dickson, famous for *Auriculas* and other florists' flowers, at Acre Lane, Brixton; E. Denyer was at the Loughborough Nursery; and J. & J. Fraser were in the Lea-bridge Road: this business was established many years ago at Leyton by Findlay Fraser, it was then carried to the Lea-bridge Road, and is now located at South Woodford as Fraser & Son. The Brothers Fraser were famous cultivators and exhibitors of stove and greenhouse plants, *Pelargoniums*, &c., forty years ago; Glendinning at this time was at Chiswick, but later he removed to the neighbourhood of Percy Cross, Fulham. H. Goldham was at Islington; H. Groom at Clapham—both famous cultivators of Tulips; the Hendersons were in the Wellington Road and Pineapple Place, St. John's Wood; the Waterers were building up their great reputations at Bagshot and Knaphill; Knight & Perry were at the Exotic Nursery, King's Road, Chelsea, as the business did not pass into the hands of Mr. J. Veitch until 1853. J. & C. Lee, originally Lee & Kennedy, were at the Vineyard, Hammersmith, now C. Lee & Son, though most of the original site of the nursery is covered by buildings; Loddiges & Sons at Church Street, Hackney; and Low & Sons at Clapton, from whence they sent out, in 1843, *Tropaeolum polyphyllum* at 42s. per plant. Further, Protheroe & Morris were at Leytonstone; Rolleston at Tooting; Weeks & Co. at Chelsea; and Whitley & Osborn at Fulham. This firm was originally established by Messrs. Whitley, Braham, & Milne; and Mr. Osborn, who came from Scotland as a clerk to the firm, ultimately became a partner with Mr. Whitley, and subsequently the head of the firm of Osborn & Sons. In 1844, there was the firm of F. & A. Smith at Hackney; but whether they subsequently removed to Dulwich, and was known as F. & A. Smith there, I cannot say. I think that Geo. Smith, Tollington Nursery, Islington, at one time a famous *Verbena*-grower, must have embarked in business a little later than the date of the accession of the Queen. J. Kernan, Russell Street, Covent Garden, was certainly there in 1842.

Going beyond the more immediate district of London, it may be remarked that Ronalds was at Brentford in 1837, Mountjoy & Son at Ealing, and the Brothers Hayes at Edmonton, or, at least, very soon after this time.

In 1837, T. Rivers, Jun., was at Sawbridgeworth, and in 1842 advertised *A Short Treatise on the Root Pruning of Fruit Trees*. J. Wood, subsequently Wood & Ingram, of Huntingdon, was sending out *Picotees* in 1837, and a new scarlet-flowered *Phlox Drummondii* in 1842. E. P. Francis was at Hertford, and in 1843 he sent out Snow's Winter White Broccoli. Youell & Co. were at Great Yarmouth, and in the same year they distributed the *Festolf Raspberry*. George Lightbody was also distributing *Auriculas* from Falkirk, and Rev. J. Tyso the *Ranunculus* from Wallingford. The Brothers Brown sent out

Dahlias from Slough; Geo. Wheeler from Warminster, Pamplin & Sons from Walthamstow, and Willmer from Sunbury. Ed. Spary, who subsequently became a nurseryman at Brighton, was in 1835 gardener at Denford House, Hungerford, and a successful cultivator and exhibitor of Dahlias; while Widnall was a contemporary raiser of considerable repute. At Reading, John Sutton, the founder of the firm, had commenced business as a dealer in agricultural seeds; sixty years ago Mr. Martin Hope Sutton, now in his eighty-second year, reorganised his father's business, and added thereto the vegetable and flower-seed branches, and the concern has now grown to be of gigantic proportions. E. Cooling, at Derby; Sharp, of Wisbech; The Dicksons of Chester; Veitch & Son, and Lucombe, Pince & Co., of Exeter; W. Chater, of Saffron Walden; J. C. Wheeler & Son, of Gloucester; J. Cranston, of Hereford; W. Bridgewater Page, an accomplished botanist and landscape gardener; W. Rogers & Oakley, of Southampton; Lane, of Berkhamsted; and Adam Paul, of Cheshunt. Adam Paul was a gardener at Enfield, and went into business as a nurseryman at Church Gate, Cheshunt, in 1807 or 1808, at a place which was originally vineries or seed grounds; he died about 1843. At that time the Cheshunt Nurseries were widely known for their Hollyhocks as well as Roses. Adam Paul was succeeded by his sons George and William, and in 1860 a separation took place, George retaining the home nursery and William established himself at Waltham Cross hard by. There were also W. Mesters, of Canterbury; Skirving, of Liverpool; R. S. Yates, of Manchester; J. Warner & Thos. Harrison, of Leicester; Pennell, of Lincoln; Sharpe, of Sleaford; Saunders, of Abergavenny; Ewing, of Norwich; John Perkins, of Northampton; Pearson, of Chilwell; T. Perry, of Banbury; E. Tilley, Bath; Maule, Sealey, & Garraway, of Bristol; Ivory, of Dorking; Jackson, of Kingston; H. Pope, of Birmingham; Backhouse, of York; and not a few of the Scotch and Irish firms were doubtless established at the commencement of the Victorian Era.

Permit me to say that I submit the foregoing information, which has been compiled with considerable care, not without some degree of diffidence, because dates in some cases cannot be accurately verified. I hope it will not be altogether unacceptable, as marking interesting trade events during the past sixty years. *Richard Dean, Faling, W.*

NEW OR NOTEWORTHY PLANTS.

MEGACARYON ORIENTALE, Boissier.*

OUR illustration (fig. 67) shows a specimen (much reduced) of a remarkable Boraginaceous plant which has recently flowered in the garden of W. B. Boyd, Esq., of Faldonside, Melrose. It was originally described by Linnæus as *Echium orientale*, and was called by Boissier at one time *Oncosma megalospermum*, but ultimately called by him by the name here adopted. It is a native of Turkish-Armenia, and is a tall, coarsely hairy plant, closely allied to *Echium*, differing from it chiefly in the smooth, ovoid, not tubercled carpels. The leaves are oblong lanceolate, narrowed at both ends, and hoary. The numerous flowers (see fig. 68) are borne in a terminal, loosely-branched pyramidal cyme. The corolla is tubular, with an irregularly five-lobed limb, the two upper petals pink, each with two longitudinal purplish streaks.

Mr. Boyd, in a note, says:—"All that I can say about the plant is, that six years ago I received the young seedling plant from Mr. Thompson, of Ipswich, and that it has been growing since then in a rocky border in rather heavy loam, which may have retarded its flowering for so many years. On carefully measuring the plant, I find that it is exactly 4 feet 3 inches high."

VANDA AMENA ×.

Another new natural hybrid Vanda has to be recorded (fig. 69, p. 259). It was imported by Messrs.

* *Megacaryon orientale* (Linn. sub *Echium*), Boissier, *Flora orientalis*, vol. iv. (1879), p. 204.

Linden of Brussels, along with *V. Roxburghi* and *V. corulea*, between which two species there is little doubt it is a natural hybrid, both the habit of the plant, and the size and colour of the flowers, being evidently intermediate between the two species named. The sepals and petals are glossy on the surface, and of a peculiar bluish-grey, marked with many blue spots. The side lobes of the labellum are white spotted with blue; the front lobe violet-blue. It is a very pleasing and distinct variety, and was accorded an Award of Merit by the Orchid Committee of the Royal Horticultural Society, when it was shown by Messrs. Linden on Sept. 21. *J. O'B.*

FIG. 67.—MEGACARYON ORIENTALE; FLOWERS ROSEY-LILAC, STREAKED WITH RED.

ORCHID NOTES AND GLEANINGS.

A SINGULAR MILTONIA.

A FLOWER of the beautiful, vinous-purple-tinted *Miltonia spectabilis* Moreliana var. *illustris*, sent by Mr. W. H. Young, Orchid-grower to Sir Frederick Wigan, Clare Lawn, East Sheen, Richmond, and which is apparently normal in every other respect, presents the curious feature of having three pairs of pollinia, each pair under its own anther-cap, the whole being symmetrically arranged in triangular form at the apex of the column, the creamy-white anther-caps within the purple wings of the column giving rather an additional beauty to the flower. The upper set are in the usual place, the pollinia attached by caudicles in the normal way. The two extra sets are arranged below it, one on each side. The anther-caps of the extra sets are attached to the column by the outer edge only, and on removing them, each discloses a pair of pollinia, which are almost free, and not attached by caudicles. It is a very singular departure from the normal form.

METHODS OF PROPAGATION.

(Continued from p. 178.)

CUTTINGS.—This mode of increasing plants, or trees is only resorted to in nurseries, in a field in the open ground. Hedge or shelter-trees, required in quantity, are so raised as well as some of fruit-tree stocks, as the Quince, Paradise, and knot Apples; while every gardener and grower knows that all kinds of Willow and Poplar are easily propagated from cuttings. Pollards are by taking straight branches of the various trees, cutting their bases to a point with an axe. They are then dropped into holes dibbled by the margins of rivers, brooks, or where they seldom fail to root freely. Almost equal facility can be raised most of the Poplars, usually cuttings of the ordinary size are taken, these, as they are so rapid in growth that they make good plants. The cuttings should be about 9 inches long, finished square at the bottom, the top being cut diagonally, and in planting 6 inches of the cutting should be dibbled in the soil, and firmly fixed by treading and affording.

In nurseries, most of the hardy-climbing plants are kept in pots plunged in the open ground, of silt, tan, coal-ashes, or other light material, that they are ready for sale, and can be transplanted at any season.

These so-called climbers, for some are only trained to climb by being nailed or tied to walls or other structures, are, as a rule, propagated by cuttings; it will well to take these first.

Akebia quinata is a rapid and graceful climber, with deeply divided ternate or quinate leaves, producing abundance of dark plum-coloured, sweet-scented flowers in the spring. Cuttings of the mature root readily in the early autumn under a bell-glass, the open; or an old plant may be taken into the houses in early spring, and the young cuttings taken off as they push, the cuttings being inserted in well-drained light soil in pans or pots, and covered with a bell-glass. Kept close and warm, the root in about a month, and may then be afforded as soon as they are hardened off, be planted into 60's. The various kinds of Ampelopsis thus increased as has before been demonstrated the head of single-eye propagation.

The Berberis tribe includes no true climber, but such species as *B. Thunbergi*, *B. stenocephala*, *B. nepalense*, and even *B. Darwini*, may be trained to cover fences or trellises with evergreen foliage, and the last-named species will generally flower or thrice a year. All may be raised in the open from cuttings inserted in prepared beds, and covered with hand-lights, though the process is often tedious. *Buddleia globosa* is increased by cutting young wood, taken with a heel of the wood of the previous season, and inserted in a north-facing position, while *Buddleia Lindleyana*, which differs so much from it in its inflorescence, may be increased in the same manner by simply taking off the young growth with a heel, inserting them in sandy loam, covering with a bell-glass, shading from direct sunshine, and protecting from frost.

Among *Ceanothus* we have some short-jointed, small-foliaged kinds, which are best increased by cuttings in gentle bottom-heat. Prepare the propagating-pan by covering the bottom with clean potsherds, on these put a layer of peat-fibre, and finish with a layer of prepared soil having a good quantity of peat and sand in its composition. Insert the cuttings firmly in the soil, water copiously, cover with a clean bell-glass, and plunge to the rim in any position where it will have the advantage of gentle bottom-heat, and the cuttings will be rooted and ready to pot off in the autumn if the process be started in early spring, which is the best period. *Ceanothus rigidus*, *C. papillosus*, *C. thyrsiflorus*, and *C. verrucosus* are best propagated in this manner; the stronger-growing varieties, of which *C. asureus* is the type, are best layered, so greatly do they vary and degenerate when raised from seed. *Corchorus japonicus* and its varieties can be increased with facility if cuttings be taken of the partially-matured wood, inserted in a prepared composition in the open border, and covered close with a hand-light. The white single-flowered kind, *Rhodotypus* of continental nurseries, and the extremely pretty Japanese form, *C. japonicus variegatus*, with its abundant, single primrose coloured flowers and elegant silver

grand glossy foliage, while the young shoots are of a distinctly reddish-bronzy tint, adding much to its beauty as a wall or fence plant.

Cydonia (*Pyrus*) *japonica* has now many fine and distinct varieties other than the well-known but mis-called "*japonica*." Colours ranging from pure white in "*nivalis*," through orange, or even yellow shades, to the deep blood-red of *Lucien Simons'* new variety, "*Simoni*;" while handsome fruits are yielded by "*Maulei*" and *Maulei superba*; and from America we have a variety named *Columbia*, with finely coloured fruits, 2 to 3 inches in diameter, which may be used as the common Quince as in tart, or to make a preserve. All these will strike, if cuttings of the mature wood be taken with a heel. *Experience*.

(To be continued.)

FRUIT REGISTER.

FRUITS IN THE UNITED STATES.

THE following notes are taken from reports collected and published by the Agricultural Department at Washington, and their correctness is therefore to be relied upon:—

As to *Peaches* we learn that, with few exceptions,

FIG. (8).—FLOWERS OF MEGACARYON ORIENTALE (NATURAL SIZE).
(SEE P. 226.)

variegated foliage, are worthy a place in any good garden.

The *Cotoneasters*, such as *C. thymifolia*, &c., may be increased by simply planting out a large bushy plant in the open, and pegging the branches down to the soil, and then partially covering them with a prepared, light compost, made firm, when every shoot will throw out adventitious roots, and eventually make a plant; or the growing points may be cut off with a heel, inserted in propagating-pans or pots, and covered with a bell-glass; and if these be plunged on a warm tan-bed, it will facilitate and encourage rooting.

Crataegus Pyracantha, or the Fire Thorn, an indispensable wall or border-shrub, should be layered or raised from seed, as I have before noted; but the very vigorous and otherwise improved variety, *C. p. Lelandi*, may be easily propagated from cuttings of yearling wood inserted in sandy soil in the open, and covered close with a hand-light, or the cutting-pan may be plunged in a tan-pit and covered with a bell-glass. I have previously remarked that by far the most free-fruited habit is secured by grafting on the white-thorn, but it is as well to have also a stock of it on its own roots. Another allied shrub, the *Photinia*, may be propagated by striking the young wood taken with a heel of mature wood, or it may, with advantage, be grafted on the common Quince-stock. It ranks next to the *Magnolias* for its

the crop is not a good one—in New York, rather poor; in New Jersey, not very good; in Pennsylvania, only moderate; in Delaware, less than 10 per cent. of an average crop; in Maryland, a small crop; in Georgia, less than half a crop; in Kentucky, below last year; in Ohio, almost an entire failure; in Arkansas, the crop is on the whole good; California, fair; Washington, never better; Oregon, promises better than last season.

Apples are reported below average except in the far west, and on the Pacific coast. From all the North Atlantic States the reports are more or less unfavourable. In Ohio the fruit has dropped off badly, and the indications are that the present condition of 46 per cent. will prove to be too high rather than too low.

Grapes in New York are reported as in rather poor condition; New Jersey as fairly good; Pennsylvania, only moderate; Delaware, generally fine; Maryland, healthy, and in good condition; Virginia, generally abundant, and thus far free from rot; Georgia, promising well; Kentucky, good condition; Ohio, suffered less than other fruits, but not indicating an unusually large yield; Indiana, injured by late frosts; Missouri, merely a normal crop, of good quality; Kansas, very satisfactory; Nebraska, over average as to yield and quality; Washington, never better; Oregon, more promising than last year; and California, promises to be exceedingly good.

FRUIT-FARM IN KANSAS.

A correspondent supplies us with the following interesting intelligence:—The "*Apple King of the World*," is the high-sounding title given to Judge Wellhouse: his orchard consists of 1630 acres, containing 100,000 Apple trees. In thirteen years he has picked over 400,000 bushels of Apples, and whenever he has spare money he adds to his orchard, and sets out more Apple-trees; growing these is his passion. Said he, "I take more delight in planting Apple-trees, and seeing them grow, than in anything else in the world." Chief precedences as to favourite varieties is given to Ben Davis, of which he has 630 acres; Missouri Pippin, 360 acres; Jonathan, 300 acres; and Pano, 100 acres. Thirty of his years have been spent in Apple culture. May he spend as many more.

TASMANIA.

We are indebted to the Agent-general for the following brief note concerning the Apple crop of the past season:—Total number of cases sent to market, 123,575 (per P. and O. Co., 63,263; per Orient Co., 55,312 cases). The season lasted from the beginning of April till the early days of June. The following are the averages of the prices obtained for the varieties mentioned:—New York Pippins, per case, 4s. 3d. to 21s.; Alfristons, 4s. 9d. to 16s. 6d.; Ribston Pippins, 4s. 9d. to 16s. 6d.; Prince Alfreds, 5s. 9d. to 21s.; Scarlet Pearmaines, 3s. 9d. to 16s.; Sturmer Pippins, 5s. 3d. to 13s.; French Crabs, 6s. to 10s. 6d.; various other kinds, from 4s. 6d. to 16s.

It is satisfactory to get an authoritative statement as to prices; it shows that a careful selection of sorts, care in packing and handling, tell on the market here.

THE WHEAT CROP OF 1897.

The rainfall in September, 1896, was very much above the average in all the chief Wheat-growing districts in England. At Rothamsted it exceeded 8 inches, being nearly 5½ inches over the average, and the temperature was above the average. There was a good deal of rain in the first three weeks of October, but the latter part of the month was fairly dry; and this dry weather continued all through November, thus enabling farmers to sow a large area of Wheat. Both October and November were very cold months. December was a wet and rather cold month. There was also a good deal of rain in the first part of January, the latter part, however, being much drier; the first half of the month was of average temperature, the last half being very cold, the thermometer during the third week showing 6° to 8° below the average. The first week in February was very wet and cold, the rainfall during the rest of the month being considerably below the average, and the temperature much above, especially during the last week, which showed 8° or 9° over the average. Very little corn was sown during the month of March, owing to constant wet weather; the month was also warm, especially during the last week, when the temperature rose to 8° or 9° over the average. The abundant hay crop was greatly assisted by the complete saturation of the soil by the March rainfall. April was both cold and dry, and this character of the weather continued throughout the month of May. A great deal of rain fell during the first three weeks of June, and the temperature being higher than average, the growth of all crops at that period was very rapid. The last week in June and the first week in July were very warm, the temperature rising 3° or 4° over the average; this was followed by a cold wave, bringing the temperature several degrees below that of the previous two weeks. The remainder of the month, and the first fortnight in August, were very favourable for harvest operations; after that a good deal of rain fell in different parts of the country, and corn which had not been carried suffered much injury. With the exception of the serious fall in temperature which occurred in July at a very critical period in the growth of the crop, there is nothing in the general character of the climate which would lead one to suppose that the crop would be below an average yield, or that so much inferior or offal

corn would exist. This cold weather continued for a fortnight in England, E., while the hot weather returned in England, S. and the Midland Counties, at the end of one week. The only remarkable feature in the climate of the harvest-year ending August 31, 1897, which has not occurred to the same extent before during our experiments, was the great rainfall in September, 1896. Rain fell on twenty-three days out of the thirty, and gave a total of 8 inches for the month, which was nearly $5\frac{1}{2}$ inches over the average of forty years.

Farmers are very well acquainted with the great value of nitrate of soda as a manure for our Wheat and other corn crops, and they also know that it is the nitric acid which constitutes its chief value; but they do not know quite so well that it is the nitric acid which is formed in our soils year by year which is one of the most important foods for our Wheat crop. It is generally found in our soils as nitrate of lime, and being exceedingly soluble in water, it rises and falls with the soil water as the weather is wet or dry, being washed out of the soil when drainage takes place. For the last nineteen years we have measured the amount of nitric acid per acre in the rain-water which has passed through the soil of one of our fields to the depth of 20 inches, the soil not being disturbed in any way, and kept free from vegetation. The average amount of nitric acid, calculated as nitrate of soda, passing through 20 inches of soil in September amounted to $19\frac{1}{2}$ lb. per acre; whilst in September, 1896, when so much rain fell, it amounted to $130\frac{1}{2}$ lb. It is quite evident, therefore, that our Wheat was sown in a soil which had been deprived of one of its most important foods to a very serious extent. Whether the roots of the Wheat plant remained near the surface instead of passing into the subsoil; whether the crop was injured, or if injured, to what extent, by this loss of nitric acid, we have no experience to guide us. Although the rainfall in the chief Wheat-growing districts of England during the month of September was very much over the average, still it was very much less than the rainfall at Rothamsted; and if the Wheat suffered injury from this cause, it would suffer more here than in other districts. Our Wheat crop is therefore not so reliable as it would otherwise be as indicating the yield of the country; still, I give the figures for what they are worth:—

* Equal to 26 $\frac{1}{2}$ bushels at 60 lb. per bushel.

† Equal to 30 bushels at 60 lb. per bushel.

‡ Equal to 27 bushels at 60 lb. per bushel.

§ Equal to 27 $\frac{1}{2}$ bushels at 60 lb. per bushel.

A reduction of 9 bushels per acre over the average of last year, upon a crop grown under exactly similar conditions, shows very clearly the uncertainty of our

climate, and our dependence upon it. Although not shown in the table, the amount of offal, or immature grain, is exceedingly large this year, and I fear it will be found to be very generally so. The only consolation which the grower possesses is, that he is receiving a better price for his product. Taking the population of the United Kingdom in the middle of the harvest year, 1897-98, at rather over 40 millions, and reckoning a consumption of 6 bushels of Wheat per head, rather more than 30 million quarters will be required. The area under Wheat in the United Kingdom in 1897 was 1,936,041 acres, and taking 26 $\frac{1}{2}$ bushels (of 60 lb.) per acre as a basis upon which to calculate the crop of the country, we get 6 $\frac{1}{2}$ million quarters. Deducting 2 bushels per acre for seed, it leaves nearly 6 million quarters available, and a requirement of 24 million quarters of imported Wheat. Whether the very high estimate I adopted as the yield per acre of our Wheat crop last year was actually exceeded, or whether the higher price of Wheat led to a reduction in the consumption, cannot be readily ascertained, but the imports amounted to nearly 1 $\frac{1}{2}$ million quarters less than the estimate required for consumption, at 6 bushels per head of the population. *J. B. Lawes, Rothamsted, September 23.*

SWITZERLAND.

M. FRÖBEL'S NURSERY AT ZURICH.

ZURICH affords a marked contrast to other Swiss towns. It is modern to the core; its railway station as crowded in proportion as any London station; its streets full of bustling life, tramways here, tramways there, boulevards like those of Paris in miniature, tree-planted streets, an imposing cathedral, and beyond all, the lake renowned in song.

There are, no doubt, old houses and old streets, for Zurich is as old as any city of the Confederation, but the hasty traveller in passing straightway to his destination does not see them, and there is, or people say there is, an imposing view of the distant Alps from the borders of the lake. It may be so, but, as far as we are concerned, we viewed the mist, but missed the view, as in so many other places this September. As we succeeded in our direct purpose to see M. Fröbel and his famous nursery, we must not complain if secondary objects were not attainable. While in his neat sanctum we are awaiting M. Fröbel's arrival, we call to mind the services he has rendered to horticulture, and we bethink ourselves of Begonia Fröbeli, amongst others, and sure enough there is hanging before us a document dated August 4, 1875, and signed by three well-known and honoured horticulturists, two of whom, Charles Noble and Archibald F. Barron, are still with us; whilst J. Townshend Boscawen has been gathered to his fathers. There too is the diploma of corresponding member of our Royal Horticultural Society, to which Mr. Fröbel points with a pride which shows that the honour is prized by our foreign friends. Stepping outside, our host laments that we have come at the worst season of the year, that now, "Oh, there is little to see; had we come in May or June it would have been different." It would have been, no doubt, but we are as used to such assertions on the part of garden-owners of all degrees as we are to the universal complaint on the part of gardeners of want of an adequate staff. We know by long experience how to discount such statements, and assuredly we found M. Fröbel's nursery, even in the middle of September, extremely interesting. We cannot pretend to dilate upon more than a small proportion of the things we saw; but in these days of lamentation over foreign competition, and of self-depreciation, it was exhilarating to find a large assortment of elegant garden pottery for decorative purposes from—Maple & Co.! There were French goods, American and Austrian wares, and wares from other countries, including Bamboos from Tonquin; but Maple & Co. amply held their own. We are accustomed to think of the Tottenham-Court-Road firm as dealing in furniture only, and not as horticultural sundriesmen. We made the discovery to the

contrary when climbing to the roof of M. Fröbel's warehouse for the purpose of seeing a magnificent hardy climber, with leaves much like those of a Scarlet-runner Bean, and which covers the walls of the house with a noble vesture of foliage. But why get on the roof to see what can be seen as well below? The answer is afforded by the circumstance that the flower-spikes of deep violet pea-shaped flowers are produced, for the present, at this elevation only. The plant is *Pueraria pachyrhiza*—we know it in England by another name, and under glass, but we have not seen it in flower, unless our memory is somewhat at fault. With like caution as to memory we record our impression that the flower has been figured in the *Revue Horticole*. In this as it may, we have here a very noble climber, which we may infer would be as hardy in England as it is in northern Switzerland. Coming down from the roof we proceed to look round, but on trying to recall what we saw, we find it impossible to classify our notes, but must just take things as we found them. Humulus japonicus variegatus is a less robust free-growing climber than the *Pueraria*, but its leaves are here unusually brightly variegated. The flowers hitherto produced are all males, so that propagation by seed is not possible. Some day, no doubt, female flowers will be produced, and then seedlings will be obtained. A bush of *Cotoneaster horizontalis*, which our condor or saye should be called *C. Davidiana*, attracts attention by its prostrate habit and profusion of small scarlet berries. "Oh, que c'est beau," remarks M. Fröbel, dropping into French for our benefit, and going on to say that the leaves, which are deciduous, become, ere they fall, almost as brilliantly coloured as the berries.

A tank full of Marliac's hardy Water-Lilies is next noted, and M. Fröbel points to a seedling of his own as of a deeper crimson colour than any yet raised. Moreover, it is one whose origin is known. Many years since our valued friend, the late Prof. Caspari, described a rose-coloured variety of the common white Water-Lily obtained from Sweden, and called it *Nymphaea alba* var. *rosea*. From seeds of this rose-tinted Water-Lily, M. Fröbel claims to have obtained the very richly-coloured variety of which we saw small flowers, the last of the season. This is to be called *Nymphaea Otto Fröbel*; at least, seeing what its origin is, we hope it will not be called *N. Fröbeli*. From *Nymphaeas* to *Opuntias* seems a long stride, but the two sets of plants are not far apart in this nursery; and here also is a bed of *Opuntia humilis*, *O. Rafinesquii*, *O. missouriensis*, and others, including *O. cananichia*, which M. Fröbel prefers to the rest. The dry summer climate of Zurich probably suits these plants better than our moisture-laden atmosphere; but when we ventured to make a remark of this nature, a grim smile passed across the face of our host, as he asked us whether we had not had experience that it did rain in Switzerland!

Close by were the dead flower-stalks of the noble Bell Flower, known as *Ostrowskya magnifica*, a plant which has proved somewhat disappointing in England. Two months entire rest after flowering in M. Fröbel's prescription for its well-doing. Next came a large batch of white-flowered *Ramondia*, of which a small proportion revert to lilac. White-flowered *Pulsatillas* were equally abundant here, though of course not in bloom at the time of our visit. The double white *Colchicum*, however, was in full flower, and is much used for bouquet work.

While speaking of white flowers, M. Fröbel points out that the variety of Japanese *Anemone* known as Lord Ardilaun is superior to the one called *Lady Ardilaun*, which is not altogether polite. Many of the blooms of Lord Ardilaun presented a "hen-and-chicken" condition, owing to axillary proliferation, or the production of flower-stalks in a ring within the perianth-lobes. Close by, under a spreading tree is a clump of *Asarum europæum*, a plant which M. Fröbel considers as excellent for covering bare patches under the shade of trees, a valuable hint to those who have a sufficiency of the plant. *Rubus xanthocarpus*, a Chinese species, is next shown as a dense low-growing bramble with slender prickly stems, elegant pinnate foliage, and yellow, agreeably-tasted fruit.

and coke are dear in Zurich, and every effort made to reduce the fuel bill, consequently the plants which in England are rarely suffered to be grown for at least part of the year. That the plants gain greatly in robustness here, where batches of *Ochna multicaulis* in a most thriving condition, and which assured flower much more freely than when they are in the stove. *Stephanotis floribunda*, *Arifolia*, *Æchynanthus*, and many other plants afford corresponding illustrations; but in summer is a different thing from its winter representative.

Of all the Orchids grown here would be the collection is large, the specimens of size, the leaves firm, healthy, and leaving no doubt of the desired. Speaking generally, abundance of moderate heat, great humidity, and ample

American *C. spectabile*. We were shown the only two plants raised from this cross, and the foreman professes his ability to see evidence of the cross in the two little seedlings before us. We shall wait before we say anything more than that it may be so.

M. Fröbel's nursery is well known as the home of many choice alpine and herbaceous plants. These are grown for propagating purposes in frames and pots, but others are planted out on rock-work. One such rockwork resembles in form the pits in which our farmers store their Mangels. It consists of a mound of porous earth, sloping on two sides, and flat on the top. On the sides of the mound, bricks of cement are placed flat against the surface of the mound, but sloping inwards and downwards. Between the chinks the plants, such as *Androsaces*, root freely. The effect is not picturesque, but there can be no question that the plants like their position.

BIRDS USEFUL TO FARMERS AND GARDENERS.

(Continued from p. 207.)

THE SPARROW-HAWK (*Accipiter Nisus*).—This hawk is somewhat smaller than the kestrel or wind-over (*Falco tinnunculus*), described in a previous leaflet. The male is about 12 inches in length, and the female is generally from 2½ to 4 inches longer. The upper part of the body of the male is of a bluish-slate colour, while the under part is brown, or greyish-brown, with bars of darker colour. In the female the body is brown, and the under parts light grey with brownish bars. Both male and female have a blue beak and yellow legs and feet. The wings are short. Unlike the kestrel, the sparrow-hawk generally builds a nest of sticks in trees, in Oaks and Firs by preference, and usually in the depths of woods. In the beginning of May it usually lays five or six round eggs of a bluish-green colour with shades or spots of brown.

The sparrow-hawk may be distinguished at once by its peculiar flight. At one time it is seen high up in the air, propelling itself by the use of its wings, then skimming along for a while without their motion. When in pursuit of prey it dashes with incredible velocity through trees and underwood, into stack yards and poultry yards, and swoops down with almost lightning rapidity upon a sparrow or other small bird, or, it may be, a young chicken, frequently quite regardless of the close presence of man.

Though termed sparrow-hawk, it does not confine its attention to sparrows, but captures many kinds of small birds, especially chaffinches and other finches, blackbirds, thrushes, wrens, and titmice. Ritzema Bos says, in his *Tierische Schädlinge und Nützlinge*, that it is considered injurious in Germany, because it kills so many insect-destroying birds. In France, according to Brocchi, it has the same reputation.

The sparrow-hawk has a bad character in Great Britain, at least among game-keepers and poultry-women. This is justified to some extent, for it undoubtedly takes young partridges, pheasants, and rabbits, particularly when it has young ones; and is a far worse offender in this respect than the kestrel, which rarely takes birds of any kind. Careful observers who have watched the nests of sparrow-hawks, have remarked that the feathers round the nest and in the pellets are chiefly those of small birds, but the feathers of game and chickens are sometimes found. If the little piles of feathers and bones often seen by the sides of woods and hedgerows, and on banks, constituting the remains of a sparrow-hawk's meal, are examined, it will be noticed that they are in the main those of small birds and mice, and not infrequently of frogs and rabbits. Selby states that in a nest containing five young sparrow-hawks he found a lapwing, two blackbirds, a thrush, and two green linnets, all recently killed, and partly divested of their feathers. It is the natural habit of the sparrow-hawk to hunt for food towards dusk, when young partridges are safe under the hen, and young pheasants are in their coops or under their foster-mothers; but when a pair have young in their nest, they hunt early and late, and at this time, without doubt, they take young game-birds, and are a cause of considerable anxiety to game-keepers.

Mice, voles, and insects are sometimes taken by this hawk. Seeböhm says that it is beneficial because it kills wood-pigeons, which are a fearful pest to the farmer in some localities. This is corroborated in the evidence cited in the Report on the Protection of Wild Birds of the House of Commons Committee in 1873, to the effect that the wood-pigeon is the natural food of the sparrow hawk, which is the only bird that can catch it.

Upon the whole, in view of this evidence, and of the opinions of several well-informed writers, and of observant countrymen, on the habits of birds, the sparrow-hawk ought not to be ruthlessly destroyed, and farmers would do well to exert their influence to prevent the wholesale and indiscriminate destruction of this and other hawks, and of owls and other useful birds, as well as such animals as weasels and stoats, which keep down rats, mice, voles, and other vermin.

FIG. 69.—VANDA AMENA. (SEE P. 226.)

are the main factors upon which M. Fröbel's success in the cultivation of these plants, and are certainly very satisfactory. Moreover, the method of growing Orchids with other plants, not, in all cases, afford them the luxury of a separate house. Among Orchids, mention may be made of *Pleurothallis Rozii*, *Vanda* in flower, *Cattleya Dowiana* in flower, *Phalaenopsis Schroderianum*, *Catasetum*, *Dendrobium Venus* ×, a cross between *D. Falconeri*; *Angraecum* of various species, which do well; and the usual *Cattleyas*.

The blocks on which many of these are grown, of Yew, a wood we do not remember to have elsewhere for like purposes. Crossing and grafting are carried on vigorously. We can only mention between *Cypripedium Curtisii* and *C. bellatulum* a very robust offspring. There are also in which *C. Chamberlainianum* takes the place of perhaps the most extraordinary of all is *C. C. Lawrenceanum* and the hardy North

Porous bricks, such as we use in England, would probably be better than those of cement, as holding moisture better. The mounds are of moderate height, so that a movable glass-roof can be placed over them as a protection from the rain when necessary. The rare, pink-flowered *Asperula athoa* was in bloom on this mound, and also the yellow-flowered *Erodium chrysanthum*, the blooms of which produce carpels only, and no stamens, so that no seeds are formed. *Epilobium obovatum*, which some fail to grow, does well here. *Viola delphinantha*, a very rare species from Mount Athos, is also growing here.

Regretting that our limited time forbade further investigation, and especially that it rendered impossible a visit to the nursery of trees and shrubs, which, in its way is, we believe, as interesting as the one we are now in, we were obliged to bid our kindly host farewell; and we recommend all plant-lovers who visit Zurich to make a point of seeing these nurseries, and, profiting by our experience, to allow themselves plenty of time for so doing.

DO ORCHIDS DEGENERATE?

By the kindness of Sir Trevor Lawrence, Bart., his Orchid grower, Mr. W. H. White, has prepared and forwarded a list of some of the species of Orchids of which the identical plants enumerated have been in the Burford collection for many years. The list is of the greatest interest as bearing on our remarks in the *Gardeners' Chronicle*, Sept. 18 last. Many of the plants enumerated come under the heading of difficult plants to manage, in some collections at least, and during their life at Burford, probably many scores, if not hundreds of the same species have been imported and cultivated for a time and then died. The specimen of *Renanthera coccinea* is of special interest, as it can be traced back to one of the earliest importations of that plant. It was in Morse's nursery many years before it came to Burford, and it is probably one of the oldest epiphytal Orchids in cultivation.

The following list comprises some of the Orchids which have been many years in Sir Trevor Lawrence's Collection:—

<i>Aerides Lobbi</i> (Russell) 1882	<i>Dendrobium fimbriatum</i> , 1882
" 1877	<i>Dalhouseanum</i> , 1882
" <i>crassifolium</i> 1877	" <i>Chrysanthum</i> 1882
" <i>Godefroyae</i> 1883	" <i>nobile</i> very old, no date
" <i>falcatum</i> 1882	" <i>tortile</i> 1884
" <i>Lawrenciae</i> (original plant) 1882	" <i>palpabile</i> , 20 years
" <i>suavisolium</i> (several) 1877	" <i>Schroderae</i> , D. Farmeri, D. thry-

THE CONIFERÆ OF THE SANTA LUCIA MOUNTAINS.

THE Santa Lucia Mountains take their name from their highest peak, which rises near the middle of the chain in Monterey County to an elevation of 6,100 feet. These mountains extend along the coast of Monterey and San Luis Obispo Counties from Monterey Bay southward, parallel with the coast. South of San Simeon Bay they trend towards the south-east, losing their identity in the low hills of the Carina Plain. From Pt. Sur to Pt. Corda they present a precipitous front to the ocean, rising abruptly from 3,000 to 4,000 feet from the very edge of the ocean. Numerous mountain streams come tumbling down through quickly descending cañons and widen them delta-like, forming a nail tract of comparatively level land. These little areas are very fertile and well supplied with the purest water; so that, in spite of their isolation and limited area, they have been taken up by settlers, who are known throughout the county as "The Coasters."

These mountains are especially interesting to the botanist, since they are the southern limit of the flora that follows *Sequoia sempervirens*, and is so characteristic of the northern coast forests. They also contain species most abundantly represented in the Sierras, as well as many peculiar to themselves. These different floras have their representative among the Coniferae, so that the distribution of the Coniferae will indicate, somewhat, the distribution of the different floras.

Sequoia sempervirens and *Pseudo-tsuga taxifolia* are associated together, as in the forests further north; but the latter is not confined to the coast cañons, being found also within sight of the ocean on the ridge above, near the Los Burros mine, and in other places not visited by the writer. The Redwoods scarcely venture above the fog line, which, in these steep mountains along the coast, is distinctly visible to the eye, as well as instantly perceptible to the sense of feeling. They are rarely found outside of the cañons, since the steep slopes of the hills offer an environment that is too dry. The soil is dry and the air also. It must not be thought that the Redwoods and Spruces here are miserable specimens. One Redwood-tree in Willow Creek Cañon is 12 feet in diameter, and a spruce-fir tree in the same cañon is more than 3 feet through. This Redwood tree is said to be the largest in Monterey County, and it is certainly a fine specimen.

On the summit of the ridge from which the ocean can be seen, *Pinus Coulteri* is the most noticeable tree. Somewhere in these mountains, in 1831, Coulter collected the first known specimens of this Pine, noted for its enormous cones. His specimens probably came from near Santa Lucia Peak, since he records it as growing with *Pinus Lambertiana*, and it is only there that the two species are found together. *Pinus Coulteri* generally grows on exposed and lofty ridges, but in these mountains it extends down the sides of the mountain on the eastern slope almost to the banks of the Nacimiento River, where it is associated with *Pinus Sabiniana*, the Grey-leaf Pine, common on the low hills of the Nacimiento and San Antonio Valleys.

On the same ridge where *Pinus Coulteri* abounds, *Pinus ponderosa* is also abundant, often growing with *Pinus Coulteri*, but frequently forming exclusive groves of scattered trees.

One poor little bush of *Juniperus californica* was seen near a never-failing spring on the Los Burros trail. Probably the species is better represented in parts of the mountain not visited by the writer. It is said to be common near Cruikshank's ranch. The trees so far noted can all be seen when crossing the range from the Los Burros mines, on the ocean side to the San Miguelito ranch, on the Nacimiento river.

Another trail further north is now known as the Plaskett trail; formerly it was called Mansfield's trail. *Pinus tuberculata* is the most noticeable Conifer on the eastern side of this trail, and the trees grow almost to the base of the mountain. Its lightly-olad branches, and numerous persistent cones, readily distinguish it from the other Conifers.

Looking down into the deep cañon of San Miguel Creek, south of the trail, but near by, and off into the distant cañon on the north that marks the headquarters of the Nacimiento River, peculiar trees can be seen lifting spire-like summits above all the others. These trees are known botanically as *Abies bracteata*, the rarest existing Fir, and confined to a few cañons of these mountains. When once seen, these trees can be recognised as far as the eye can reach. While there are few individuals, comparatively, the number of small trees coming up in San Miguel Cañon assure us that the species is in no danger of extermination.

Mr. E. C. Mansfield and the writer visited this locality on May 1 of the present year, to obtain flowering specimens, which had, until then, never been collected. The trees were in full flower; the pollen had begun to float through the air, and near the tops of all large trees female flowers were plainly to be seen. Coulter records that only the middle branches bear cones. This was not so with the trees observed in this cañon. Owing to the great difficulty experienced by Mr. Mansfield in reaching the topmost boughs and in

specimens, only a few pistillate flowers were seen, and these Mr. Mansfield carried down, and the twigs, to which they were attached, in such, so as to keep them intact on the branches. The specimens are in the herbarium of the Californian Academy of Sciences, duplicates having been sent to S. Sargent to be represented in the *Silva of America*. The staminate flowers were more easily collected, being so much more easily dried.

Firs seen in this cañon had lost their lower branches, and therefore lacked the symmetrical outline from base to summit which the more perfect ones exhibited. The writer some years ago

bird-nests set with diamonds. The beauty of the cone-laden branches can perhaps be imagined.

Further north, near the foot of Santa Lucia Peak, a third trail (spoken of above) crosses these mountains. It is known by the name of the Santa Lucia trail, and is the most rugged but most attractive of all the trails. Long ago it was much travelled by the Indians, but now a traveller rarely crosses the mountain by that route. It passes through the only grove of *Pinus Lambertiana* now left in these mountains. The writer can never forget the amazement and delight experienced when coming upon this grove. One or two young trees had been seen on the way up the eastern slope, but their identity was only guessed

LYCASTE DENNINGIANA.

Our illustration (fig. 70) represents this very fine species, which was originally described by Professor Reichenbach in the *Gardeners' Chronicle*, December 23, 1876, p. 808, the plant being dedicated to Mr. Denning, then gardener to Lord Londesborough. For many years the plant has been very rare, and it was a pleasant surprise to see it at the Royal Horticultural Society's meeting on September 21, on which occasion it was shown by F. W. Moore, Esq., Director of the Royal Botanic Gardens, Glasnevin, Dublin, the home of so many rare and curious Orchids and other plants. *Lycaste Denningiana* is a native of Ecuador. Its fine flowers have the sepals and petals very pale yellowish-green; the showy labellum reddish-orange, changing to red-brown. When shown it received an Award of Merit.

BOTANICAL EXPLORATION IN YUNNAN.

DR. HENRY, the well-known Chinese botanist, is now stationed in Yunnan. The following extract from a letter recently received from him gives some interesting particulars of this botanically rich region:—

"Customs, Mengtse, par Laokay, Tonking.

"September 5, 1896.

"As regards botany, e.g., this region—on the outskirts of which I was stationed at Ichang, and now am here again on another border of it at Mengtse—is, I imagine, the most interesting in the world. It is evidently the headquarters of most of the genera which are now spread all over Europe and Asia in great part. The geology is quite unknown, and it is a combination of knowledge of the ancient history of the region geologically, and of the flora, which will explain much that is obscure in the present distribution of species. I have told you of the immense, universal, and peculiar deposit of red clay which covers Yunnan, extending into the Shan States. This perhaps speaks of glaciation, and perhaps it is to glacial phenomena that the present richness of the flora is due.

"I intend to go on collecting vigorously, and hope to rival Delavay in Yunnan. His 3000 species will be hard to beat.

"The country immediately around Mengtse is not so very rich, as it is bare of wood and water; but in all directions at two to four days' distance there is splendid country. I have just had a native collecting in the mountains south of the Red River near the French frontier, and he has brought back from the virgin forests of a high mountain about 100 interesting species, e.g., he has re-found *Tetracentron* (a genus of *Trochodendrea*), perhaps a new species, at any rate a variety, of the Hupeh plant. He has also brought me undoubted wild Tea. Hitherto the Tea-plant has been found wild only in Assam, the cases of its spontaneity recorded from China being very doubtful. In all my trips in Szechwan and Hupeh I never met it. The present specimens are above suspicion, coming from virgin forest, and at an immense distance from any Tea cultivation, the nearest being P'u-eh, 200 miles west. Bretschneider in *Botanicon Sinicum*, part ii., p. 130, has some remarks on the antiquity of Tea in China, and it was not till the sixth or seventh century that it came into general use. It is probable that it was found wild in these southern provinces, which did not form a part of the ancient Chinese empire, and I daresay it will be found wild in these mountains from Mengtse to Szemao. It is not probable at all that Tea came so far away as Assam.

"My native also brought back some interesting *Feras*, pretty *Cyrtandrea*, &c., and some specimens in fruit of the curious *Lysimachia*, the leaves of which have a delicate but strong fragrance. They are used for scenting hair-oil by the Chinese. Perhaps some of the seed is ripe enough for me to send to you for cultivation.

"I have had enquiries from a London firm about soap-trees. They wish to buy the fruits of these in quantity, as they have brought out some patent or

FIG. 70.—FLOWER OF LYCASTE DENNINGIANA: SEGMENTS PALE YELLOWISH-GREEN; LIP REDDISH-ORANGE.

o trees in a gulch further north, which the Lucia trail crosses, where the lowest branches almost to the ground, and the trees tapered to cones with long, pointed tips waving like in the breeze. The trunk, at the upper end down long, slender branchlets, that droop like those of the Weeping Willow or Weeping

Even the upper boughs have a tendency to droop downwards, thus rendering the foothold of an arduous climber somewhat precarious, since the slightest breath of wind sways the slender upper axis round.

Mountaineers are all enthusiastic in their opinion of this tree, which they name the "Silver Tree." When the cones have attained full growth they have a purplish hue, and the long, slender, drooping branchlets become gemmed with drops of resin, so that the whole part of the tree seems full of odd-looking

at until the magnificent trees far above and beyond were discovered. *Pinus Lambertiana* is said to have been abundant formerly on the slopes of Santa Lucia Peak, and a few trees are yet left. *Libocedrus decurrens*, also, then grew on the mountain. While the San Antonio Mission flourished, the best timber on Santa Lucia Peak was cut down, and these two valuable species were almost utterly destroyed. In those days it is said that the Nacimientos and San Antonio Valleys were "black with Indians." Their houses, fields, and aqueducts gave life to the hills and valleys over which the beautiful Oaks alone now seem to hold sway. Were it not for the few survivors in almost inaccessible places, and the timbers and other relics of the San Antonio Mission, the story of the former prevalence of the Sugar Pine and Incense Cedar would scarcely be credited." *Alice Eastwood*, in "*Erythea*," June, 1897.

other which demands a large consumption of these fruits. I suppose the *saponin* therein is the base of the patent (for washing fine fabrics, hair wash, &c., perhaps). They didn't say what their patent was.

"A large number of soap-trees occur in China, and I would write a note for the *Bulletin* on the subject, as it is of perhaps considerable commercial importance, but one thing is wanting. The species of *Gleditschia* require revision. Four are mentioned in the *Index Fl. Sin.*, i., p. 208, *et seq.*, but since then there is a new one from Hupeh and another from Yunnan. There were also specimens of mine at Kew from *S. Formosa*, which are not yet matched with any described species.

"The chief soap-trees are *Sapindus Mukorossi*, *Gymnocladus sinensis*, and all the species of *Gleditschia*, excepting *G. officinalis*, Hemsley, which has a small pod only used as a drug. The fruits of these are very generally used in China in lieu of soap, and for washing the hair the Chinese ladies say they are superior to alkaline soaps.

"I have tried, in vain, to get a Lolo teacher to instruct me in the language, and teach me their method of writing, now almost gone out of use, if not entirely. The MSS. of the Lolos are as yet undeciphered.

"I told you about the plague, its ravages amounting to actual decimation of the inhabitants of Mengtee town. It suddenly ceased on or about August 8, a few cases having appeared in the surrounding villages just before, and it is now gone completely from this neighbourhood, though I hear that it is now prevalent in a town some twenty miles away on the other side of our mountains.

"My collector also found some *Laurines* the absence of which was rather puzzling to me. I am sending him off in another direction in a day or two. The mountains he botanised over he described as lofty, and covered with thick forest of immense trees. Bears occur there, a sure sign of virgin forest, as far as my experience goes in China.

"I have little more to add, as I have not been away lately on any interesting trips. I, however, find much to interest me in the mountains around: it is not everywhere you come across plants you have not seen before, almost every day. The Orchids are plentiful and rich in species.

"This place is isolated in the extreme, and it takes such a time to receive letters. As regards stores, they come after delays of months. I have nearly finished all my shoes, and there are new pairs, I hope, all along the way, but they do not seem to come.

"It is rather easy travelling about here, as mules are cheap and numerous. I have just had a tent made for trips. The savage villages in the mountains are too dirty to stay in, even if one always found these queer folk in the humour to take one in. What I mean by 'too dirty' is something awful, as I put up quite comfortably with the huts of the Chinese in Hupeh, which were comparatively clean.

"The Chinaman is of course superior to these Shans, Lolos, Miao-tzu, in energy and various other laudable qualities, but the Miao-tzu and true Lolos of the mountains have more pleasant manners in many ways—at least, I like their looks and way of talking.

"Does no geologist ever dream of investigating these regions? Yunnan is well known for its mineral wealth. It is easy enough now getting here from Hongkong by way of Tonking." *Kew Bulletin*, February and March, 1897.

FLORISTS' FLOWERS.

DAHLIAS AT MR. C. TURNER'S SLOUGH NURSERY.

"TURNER'S" was a household word among florists all over the country at one time, and if it be less so at the present day, it is because there are so many more persons engaged in the florists'-flower business, and not because the nursery has in the least degree deteriorated. The raising of Dahlias from seed, and the propagation of the plants in other ways, still

forms one of the specialties of the firm, and not less so now, than in bygone years. As the popularity of one kind of florists' flower wanes, another comes to the front to be, in its turn, probably relegated to the limbo of half or wholly forgotten plants.

The show variety of *Dahlia* is, in so far as southern growers are concerned, on the road thereto; but in spite of the smaller amount of interest taken in it, numbers of all the best varieties are still grown here, and a large trade done in the plants, chiefly with cultivators in the northern counties. The favourite section of the *Dahlia* at the present time in the south is the so-called "Cactus-flowered" varieties, the flower of these varieties being very lasting as well as ornamental when cut. Knowing that every good variety is afforded a fair trial at Slough, I recently visited the nurseries with a view to making a selection.

The Cactus Dahlias are accorded the greatest amount of space, being followed closely by the show and Pompon varieties; of the first named variety, many that are new, and under name as well as unnamed seedlings, were remarked in the trial beds. Among the yellows was Mrs. H. Turner, a very showy flower, not too large. It is a plant which throws flowers early as well as late in the season; but the mid-season flowers are apt to become too large, flat, and not to partake of the true Cactus shape.

Lady Penzance is a pretty yellow flower, good for cutting where short stems will suffice, but which has the disadvantage of not throwing up well, thus the blooms are partially hidden among the foliage. Of flowers of red and orange-scarlet shades, there are far too many. Fusilier is a free and good variety of full size, and of the true Cactus shape; *Gloriosa* grows tall, and has brilliant crimson, partially incurved flowers; Fantasy represents a dwarf form of the preceding, but with smaller flowers; Harmony is a reddish-bronzy flower exhibiting a pleasing combination of colours—an improvement on Countess of Gosford; Starfish is a perfect "Cactus variety" of an orange-scarlet colour, and every flower comes true—a decided acquisition—its height is 4 feet. Mrs. H. Cannell is of an orange-buff colour, and a good flower; Cycle is in colour ruby-red, grading off to a lighter hue at the tips of the florets, the flowers borne erect on a stout stalk; Endymion is a bright cerise-coloured flower with twisted florets; Iona of a terra-cotta hue; and Mrs. Beck is of a rich reddish salmon hue, and, like the preceding variety, it is free flowering. Charles Woodbridge is a new variety of a plum colour, a fine type of Cactus-shaped flower, and distinct; Cinderella is of the same class as the preceding, but of a deep shade of velvety purple; Delicat and Mrs. Wilson Noble are varieties of a salmon-pink tint, free flowering, and of moderate growth. Of dark varieties, Matchless, although a telling colour, is not a true Cactus; Harry Stredwick, one of this class, possesses flowers of a more perfect shape; and a variety of dwarf growth, with perfectly-shaped flowers of a crimson-maroon colour was found in a Slough seedling named Hyperion, the flowers of which are thrown well above the foliage. A good white Cactus *Dahlia* appears to be still lacking, the variety Mrs. A. Peart being of a creamy-white, the flowers of which are often misshapen; and Mrs. Francis Fell, although a free-bloomer, has slender flower-stalks, causing the flower to droop and show the reverse of the pinkish florets. It passes for a pure white, however, when cut with short stalks as set up for exhibition purposes.

For effect in the beds, the Pompon *Dahlia* with its numerous, small, erect flowers is perhaps the most effective. The best in this class are, whites, Lady Blanche and White Aster; orange-scarlet, Isabel; clear yellow, Whisper; deep crimson-maroon, Douglas; light orange scarlet, Phoebe.

The single-flowered Dahlias seem to be dropping out of cultivation, although some of the starry, or single-flowered Cactus ones, are useful for cutting, and last fairly well when taken in the newly-expanded state. H.

THE WEEK'S WORK.

PLANTS UNDER GLASS

By G. H. MAYCOCK, Gardener, Luton Hoe Park, Luton.

The Fernery.—With the approach of a season of greater moisture in the outer air, that of the fernery must necessarily undergo a change, and damping down,

and affording water to the plants must be lessened. One damping down, and that early in the day, when also the application of water to those plants that need it may be carried out. This lessening of moisture should not be carried so far as to make the air parched, or thrips and red spider will overrun the Ferns. In collections it is very difficult to meet the requirements of each plant, but something can be done by arranging together in groups those species that need similarity of treatment. Some species thrive beneath the shade of taller Ferns. If the house be a lean-to, the back wall may have fibry-peat and loam secured to its face by means of small-meshed fencing-wire, in which *Davallia*, *Nephrolepis*, *Nephrodium*, *Pteris tremula*, *Asplenium*, and others may be planted. Such walls afford a quantity of fronds for cutting, and they are useful adjuncts to the indoor garden. The *Todea Hymenophyllum*, and *filices* generally, should have a structure to themselves; and some of them thrive in the crevices found in some old stone-walls, and also do well in the ordinary Fern-case. The *Todea Hymenophyllum*, &c., should be kept continuously moist winter and summer, but not by syringing them overhead. The proper temperature of the warm fernery at the season is 55° by night, and 60° by day, but a few degrees more than these figures in mild weather doing no harm.

Centropogon Lucynia.—This showy plant does well at this season in the intermediate house if the growth is nearly completed. Old plants in baskets (see p. 75, in vol. xxi.), will have made shoots 2 to 3 feet long, which should now be tied out round the sides of the baskets at regular distances apart, a few supports being likewise afforded those in the centre of the plant.

Agatheae celestis.—Those plants which up to the present have stood in cold frames may now be placed in a house with a temperature of 50° at night, and 5° higher by day, when large quantities of the flowers will appear on them in a short space of time. *Agatheae celestis* should not be afforded manure-water, unless it should appear exhausted, when farmyard liquid manure will, if diluted, be of benefit.

Francoa Ramosa, or *Garland-flower*, is a pretty plant, useful for furnishing cut flowers in the spring and summer. Seedlings of it which were raised in the spring and pricked off into small pots, will be sufficiently rooted to repot into large 48's, in which they will flower in the spring of next year. A compost of loam three-quarters, and leaf-mould one-quarter, and enough silver-sand as will give porosity, will suit the needs of the plants. Being repotted at this date, the plants will winter safely if plunged to the rims in coal-ashes in a cold pit. The plants may also be propagated by division, potting these bits in small 48's.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Removing Root-suckers from Fruit-trees.—Wall-trees frequently produce root-suckers, and if the Dutch-hoe be used repeatedly to destroy seedling weeds, these young suckers are cut down by the tool, but they appear again more numerous very soon afterwards. Owing also to the fact that the top-growth of wall-trees is more restricted than is the case with standards and bush-trees, the disposition to produce root-suckers is increased. The present time is a good one to go carefully over such trees, and remove, by the aid of a spade and sharp knife, all the bunches of roots which have in the way stated formed on the main roots, afterwards replacing the soil and making it firm.

Fruit-tree Stocks worked during the present year should have all suckers coming out below the graft or bud rubbed off as soon as they appear. This applies to Apricots, Peaches, Plums, and Cherries, and the result will be that the flow of sap will be directed into the development of the scion. Neglect of this has resulted in many failures among young fruit-trees.

The Harvesting of Apples, Pears, Filberts, Walnuts, Quinces, and Medlars, should receive almost daily attention during the present month, the different varieties of Apples and Pears very quickly succeeding each other in order of ripening. The fruit should be put on the fruit-room shelves in the order in which they will become fit for use. When fruit readily parts from the spur on being lifted to horizontal position, it is fit for gathering. Medlars and Quinces may be left on the trees till the end of the month. Walnuts and Filberts should be gathered as soon as they come away freely from the trees. Gather

Filberts for pecking in jars with their husks when dry, and place the jars in a cool room or cellar out of the reach of mice, covering the mouths of the jars with a piece of slate, or a seed-pan of the same size. I may repeat once more that the greatest care should be exercised in the handling of all fruits, but especially Apples and Pears, or they will be certain not to keep well.

THE KITCHEN GARDEN.

By W. FORK, Gardener, Highclere Castle, Newbury.

Lettuce and Endive.—A good supply of salad during the winter months may be ensured by lifting a number of Lettuces and Endive from the open ground when about half grown. Remove them with balls of soil attached, and plant them from 9 inches to 1 foot apart in cold frames. If the work be carefully done, the plants will receive very little check, and soon form large plants that will keep in good condition much longer than those which may be lifted and stored in frames when full grown. The frame-lights should be removed as much as possible for the present, merely putting them on in the case of heavy rains, which, in conjunction with early frosts, may prove damaging to them. Plenty of air may be admitted at such times by tilting the lights at the back. Endive, now large enough for use on the open quarter, may be protected and blanched by gathering the leaves up and tying them firmly at the top whilst quite dry. This will blanch them perfectly, and prevent moisture from reaching the hearts of the plants. In the case of the small, curled varieties, blanching may be done by laying a roofing-tile over the plants for a few days.

Late Potatoes.—Take advantage of fine weather to proceed with the lifting of the late Potatoes. It is important that the tubers be dry before being stored away. If the tubers will not be required for consumption for a few months, there is no better plan than that of putting them into clamps on the ground. Put them in long, narrow ridges, about 4 feet wide at the bottom, and 2½ feet high. Cover well with dry straw or Fern, and place a good thickness of soil over this, taking care to leave sufficient openings along the ridge to carry off any moisture arising from sweating, but closing them with a bunch of straw.

Onions.—Summer-grown Onions should be got into their winter quarters. Any cool, dry place will be suitable, and a few degrees of frost will not hurt them in the least, provided they are dry. If plenty of shed-room be available, the bulbs may be laid thinly on shelves after being divested of the loose skin. Otherwise they may be tied into bunches or ropes, and hung up thickly to the rafters or walls. Onions should be examined frequently for decaying or growing bulbs. Thick-necked or imperfectly-finished bulbs should be kept by themselves for present use, long-keeping varieties being likewise stored separately for late consumption. Keep autumn-sown plants free from weeds, and on a dry day stir the soil with the Dutch-hoe. A dusting of fresh soot afforded occasionally is of great benefit to the Onion.

Kidney Beans.—These plants will now need protection from early frosts, and so prolong the season outdoors as much as possible. Growth even now is very slow, and a slight frost will quite stop the supply. Dwarf varieties may be protected somewhat by placing spare frames and lights over them; or hoops and mats placed over the rows will protect them on cold nights.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Ledbury.

Vines.—In the earliest houses the Vines have become thoroughly ripened, and the work of cleansing and pruning them may soon be commenced. In cases where the wood may not be ripening so quickly as could be wished, it will be well to prune back the shoots to five or six eyes so that they are exposed to the sun. This shortening will also cause the back buds to swell up considerably; and if manure-water is abundant afford the inside borders a good soaking with same. Vines it is intended to start on November 1 should be pruned and got ready as soon as the leaves commence to fall, taking care not to prune back very closely, if the Vines are aged. Leave a good plump bud, even if it be at some distance from the rod, for a long spur is more tolerable than a worthless bunch of Grapes. The houses should be washed well with soft-soap and water, and if the Vines are free from bug, a good washing of Gishurst Compound with a little flowers-of-sulphur added will be all that is needed. Apply the liquid when warm, and rub it

into the bark with soft scrubbing-brushes. Remove old matting ties from the wires. Take clean away everything from the surface of the border, and if the top soil is at all spent, carefully point it over with a fork and rake off as much of it as can be done without injury to the roots. Then give a sprinkling of Vine-manure, or of finely crushed bones, and cover with a layer of good friable-loam to which has been added a little lime-rubble and soot. B at this firmly with a steel-fork, and cover with a layer of long stable-manure. The outside borders may be treated in the same way, making sure that the roots be kept near to the surface. A good watering with tepid-water will be all that remains to be done when closing the house.

Mid season Houses.—Trim off all lateral growths upon Vines from which the crop has just been removed, and then syringe them thoroughly with a mixture of soft soap and water. If the borders be in the least degree deficient in moisture afford them water abundantly, and throw the house wide open night and day. As these structures are often required for housing Chrysanthemums, the Vines may be pruned or half-pruned before these plants are brought in.

Later Houses containing ripe Grapes must not be kept too damp; at the same time the roots must be afforded sufficient moisture, or the Grapes will shrivel. If water be necessary, choose a nice bright morning, and do the work early, so that the house can get moderately dry before closing time. If the nights become cold and foggy, close the vineries at night, and open them as soon as the mist has cleared off in the morning. Remove decaying berries promptly, as one left in a bunch will soon spoil the whole bunch. If Muscats are lacking in colour, the foliage may be pushed back, to admit all sunlight possible. Keep a sharp look out for injury from mice.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Birtford, Dorking.

Up to the time of writing, very little fire-heat has been needed in any of the houses, but in October we must be prepared for cooler weather; sudden changes occur, and usually in the early morning hours, causing a drop in the heat of the houses, which the gardener is unable to guard against. On these occasions no application of water to the plants or damping down should be done till the proper degree of warmth has been reached. For the next few weeks the night temperatures may be as follows:—East India-house 65° to 70°, Cattleya and Mexican-house 60° to 65°, and the intermediate-house 60°; the higher temperatures being maintained only when the external air is near to about 45°. When banking up the fire, the dampers should be so arranged that there may be a fall of several degrees by the morning-hours. Such of the deciduous or semi-deciduous Dendrobiums mentioned in a former calendar, which are now being rested, will be quite safe in the greenhouse or other airy structure with a temperature at night of about 55°. As the weather gets colder, and the pseudo-bulbs ripen, a temperature of 50°, if the house be kept dry, will suit them. The cool or Odontoglossum-house may be kept at 50° to 55° while the weather continues mild, but when colder weather renders it necessary to use the heating-apparatus, the lower temperature named should not be exceeded. The Masdevallia-house should at all times be 2° or 3° warmer than the cool-house, and to prevent the black marks so often seen upon the leaves of these plants, the atmosphere should always be several degrees below saturation point. The external air being more cool and moist now than during the heat of summer, there is no need to damp down so often. From the present time a moderate amount of damping of the East Indian, Cattleya, Mexican, and intermediate-divisions morning and afternoon will suffice. In the cool-houses one thorough damping down in the morning will suffice, but after a bright sunny day, the floors may be sprinkled in the afternoon. It is important at this season to let the houses get comparatively dry during the middle hours of the day, doing this regularly having the effect of checking the development of spot on the foliage, and maturing the growths. Every house should be well ventilated when the weather is favourable for so doing. The top-lights of the East Indian-house may be opened to a moderate extent for a few hours in the middle of warm days; the Cattleya, Mexican, and intermediate-houses being also well ventilated whenever the external air is above 50°. Abundance of air must be given to the occupants of the cool-house when outside it is not lower than 45°. In the warmer divisions, a certain amount of discretion must be used in the matter of ventilation; it

being improper practice to admit large volumes of cool air into the house all at once, a better method being to slightly open the ventilators, increasing the amount of air admitted as the inside temperature rises.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maidenhead.

Calceolarias.—During the next ten days the cuttings required for furnishing plants for next year's bedding should be taken. From many years' experience, I find that the cuttings are more easily struck at this time than earlier. After the heavy rains in the early part of September, the Calceolarias made free growth, and good cuttings should be readily obtainable in the form of strong growing points, rejecting those which have incipient flower-buds. The cuttings may be successfully rooted in a cold frame set on a hard bottom of coal ashes, on to which some rough leaf-soil to the depth of 3 inches is placed, and on this a layer of the same thickness of finely sifted, moderately light soil. Let the bed be made smooth, with a light slope from the back to the front of the frame, and make it firm. Over the mould some silver or clean river or sea-sand may be strewn to the depth of half an inch. Put in the cuttings by means of a rather blunt-ended dibber of ¼-inch in diameter. If dibbled in 3 inches apart, the cuttings will have sufficient space to grow till early spring, when they should be transplanted into other frames. Afford the bed one good application of water, and keep the frame close and shaded from bright sunshine for three weeks, that is, till roots have formed. Protection with mats or litter should be afforded to exclude frost during the winter. Cuttings of Gazanias and Antirrhinums are as readily struck in the same manner if inserted at this date.

Violas.—These are usually required for early blooming in the flower-beds, and as the plants are more floriferous and satisfactory if newly planted each year, either by being taken up and divided, and the younger of the rooted pieces selected for re-planting at this season, or by taking cuttings now, and rooting these in a cold frame, as recommended for the foregoing; or, if a frame be not available, then on a sheltered border. The smaller rooted bits of the old plants—but not the older portions of these plants—may also be pricked out on a border, and these will make good plants for transferring to the beds in the spring. They will, however, come in better for late than early flowering, that is, the bloom will come late and last through the summer months, if the precaution be taken to manure the ground they will occupy with well decayed and pulverised spent mushroom-bed dung, or that from old hot-beds, or even with leaf-mould.

Viols.—The plants have grown considerably since September set in, and both single and double-flowered varieties have formed good strong clumps, and flowers are now plentiful on many of the varieties. The double-flowered varieties may now be lifted from the open ground and planted in frames. The bed of soil on which they are planted should be laid on an unsinkable bottom, and it should consist of good loam and leaf-soil in the proportion of two-thirds of the former to one-third of the latter. The bed should be so made that the plants are almost touching the glass. A portion of the single varieties, if they have been conveniently planted for the purpose, may have frames placed over them later on, and protection afforded them in frosty weather.

Bedding-plants.—The whole of the Pelargoniums which have been struck in the open should be potted-up forthwith, and placed under glass. If any of the old plants are to be saved, these should be potted-up without delay, shortening the roots, but not the tops, and putting them into pots as small as will accommodate the roots, using as a potting soil sandy-loam. They should not receive any water for a week or two; but if the sun be bright, shading should be put over them for a few hours. Have protecting-material placed handy, so that beds of tender plants still in a presentable condition, or which it may be desirable to save, may be quickly covered in the event of frost occurring.

SPRING WHEAT IN THE UNITED STATES.

We learn from the Agricultural Department at Washington that the condition of spring Wheat (86'7), 54·5 points lower than in July, but 7·8 points higher than at the corresponding period last year, and 4·5 points higher than in the August average for the last ten years.

APPOINTMENTS FOR OCTOBER.

SATURDAY,	Oct. 2	Société Française d'Horticulture, London.
THURSDAY,	Oct. 7	Isle of Wight Horticultural Society, Meeting.
		Ayrshire Gardeners' Society, Meeting.
TUESDAY,	Oct. 13	Royal Horticultural Society's Committee.
		National Chrysanthemum Society's Show.
TUESDAY,	Oct. 26	Annual Dinner of the United Horticultural Provident and Benefit Institution.
		Royal Horticultural Society's Committee.

SALES FOR THE ENSUING WEEK.

MONDAY,	Oct. 4	Dutch Bulbs, at Protheroe & Morris' Rooms.
		Unreserved clearance sale of Stove and Greenhouse plants at the Gardens, Cowdray Park, Midhurst, by Protheroe & Morris.
		Dutch Bulbs, at Stevens' Rooms.
		Dutch Bulbs, at Protheroe & Morris' Rooms.
		Unreserved clearance sale of Plants, Lights, and utensils at The Vine Nursery, Downs Road, Clapton, by Protheroe & Morris.
TUESDAY,	Oct. 5	Clearance sale of well-grown Eucalyptus, Palma, and other stock at The Saxe Weimar Nursery, St. Edward's Road, Southsea, by order of Mr. T. J. Short, by Protheroe & Morris.
		Dutch Bulbs, Palms, Azaleas, and other plants from Ghent at Stevens' Rooms.
		Dutch Bulbs, Azaleas, Camellias, Roses, Perennial Plants, &c. at Messrs. Protheroe & Morris' Rooms.
WEDNESDAY,	Oct. 6	Unreserved two days' sale of Nursery Stock at The Tunbridge Wells Nurseries, Tunbridge Wells, by order of Messrs. T. Cripps & Sons, by Protheroe & Morris (two days).
		Unreserved sale of imported Orchids, Dutch Bulbs, Lilies, &c. at Mr. Stevens' Rooms.
THURSDAY,	Oct. 7	Dutch Bulbs, Azaleas, Camellias, Perennial Plants, Roses, &c., by Protheroe & Morris.
FRIDAY,	Oct. 8	Dutch Bulbs, and imported and established Orchids at Protheroe & Morris' Rooms.
SATURDAY,	Oct. 9	Dutch Bulbs at Stevens' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—53° 4'.

ACTUAL TEMPERATURES:—

LONDON.—September 29: Max., 70°; Min., 54°.
PROVINCES.—September 29: Max., 60°, at York; Min., 50° at Sunning Head.

The Fruit Show.

For the fourth year in succession the Royal Horticultural Society has opened an exhibition of British-grown fruits at the Crystal Palace. No one doubts the influence that such a display exercises upon British fruit-cultivation. Its effect is to demonstrate that in our climate it is possible to produce hardy fruits, especially Apples, as fine or finer than those from any other part of the world. It is a grand advertisement, and one that is needed, for if horticulturists know well enough what first-rate English-grown fruit is, there are numbers of the populace who do not. It is advisable, nay, essential, that they should do so, and nothing can effect this but the repeated exhibition of fruit in the finest condition it can be obtained. Such a show also encourages a desirable emulation amongst gardeners, and tends to raise the average standard of excellence in culture.

We regard it as a happy circumstance, therefore, that in 1894 the Royal Horticultural Society decided to endeavour to revive the Annual Crystal Palace Fruit Show that had been allowed to lapse. This was done on condition that those interested in the matter would subscribe £100 towards the prize fund, and for the fourth time this condition has been met. The speeches of the Chairman of the Crystal Palace Company, and of the President of the Royal Horticultural Society at the luncheon were satisfactory, inasmuch as they indicated a general and earnest desire to continue the show from year to year. Nothing has been wanting on the part of the Crystal Palace Company to

make the show a success, and the Society very fully appreciates the consideration that has been shown. Notwithstanding certain rumours to the contrary, we gather from the chairman's speech that the Crystal Palace is not likely to be sold to this or to that body at present, and for an indefinite time the finest place for such a purpose in the metropolis will be available for the annual fruit show. The present exhibition is satisfactory to all concerned, and a pleasant surprise in such a season as 1897. The moral seems to be that, let the season be never so bad, there will always be sufficient good hardy fruits to make a first-class show.

The lecture delivered on the first day by Mr. BUNYARD was upon "Progress in Fruit-cultivation during QUEEN VICTORIA'S REIGN," and we cannot do more for the moment than briefly refer to some of the subjects then touched upon. Mr. BUNYARD invited his audience to imagine a typical garden of 1837. He explained the system of fruit-culture then practised, and enumerated the varieties with which such a garden would be furnished. The leading fruit-tree growers of that time were mentioned, and the introduction of continental novelties and methods referred to. Mr. BUNYARD spoke of the grand work done by the late THOMAS RIVERS, and alluded to the increase of fruit culture under glass.

In such a review of the development in fruit cultivation, considerable prominence has necessarily to be given to the work done at Chiswick under Mr. BARRON, especially the first Apple Conference, an event that was the means of effecting incalculable good. A tribute was paid to other workers in the cause of popularising and systematising fruit-culture in this country, some of them by their pens, others by actual practice, and the excellence of the work done by the Fruit Committee of the Royal Horticultural Society was acknowledged. Carefully-compiled lists of varieties of fruits known in 1837, and still cultivated, and a list of fruits certificated by the Royal Horticultural Society during the sixty years, are included as appendices to the paper. Interesting notes upon the introduction of some of the best fruits; and a review of the Pomological literature during the present reign were given and a list added of the best fruits in 1841, being a reprint from the *Gardeners' Chronicle* of that date.

The New House at Kew.

In vol. xvii. (N.S.), p. 636 (1882), and pp. 16 and 19, vol. xi., 1892, 3rd S., we published reproductions of the original design by DECEMUS BURTON for the Temperate-house at Kew, only a portion of which was completed in 1862, namely, the central block and the two octagons. The building of the two wings was postponed presumably through lack of funds. One of these wings, the south, has this year been built, thanks largely to the exertions of the Right Hon. J. CHAMBERLAIN. In its main features, the new house is in accordance with Mr. BURTON'S design, the only deviation being in the use of lighter material and more glass, an improvement on the original from the cultivator's point of view. The house is a handsome quadrangular structure, with a high central span land lean-to sides. It is 38 feet high, 112½ feet long, and 62½ feet wide. Except the paths, the whole interior is laid out in beds, with the hot-water pipes placed in a grating-covered trench in the central path and round the outside walls. These beds, which are from 4 feet to 5 feet deep, are filled with from 18 inches to 2 feet of drainage, through which agricultural drains run, and from 2½ feet to 3 feet of soil. This is chiefly pasture-loam, with which river-sand and lime-rubbish has been freely mixed. Altogether

about 1000 loads of material have been placed in the beds. At the south end, some large masses of rock have been arranged for the accommodation of Agaves, Cacti, Euphorbias, and such-like plants.

This house is to be devoted to plants requiring an intermediate temperature, and a liberal allowance of sunlight. The minimum winter temperature will be about 50°.

Planting operations began in April, and the house was opened to the public on July 23. The growth of the plants generally has been surprisingly vigorous, very few indeed of the 500 species planted having failed. There can be no doubt that the bed system is preferable to pot-culture for plants in large houses, that is if rapidity of growth with luxuriance are desirable. This has been abundantly shown already by the growth made by plants previously cultivated in pots, some of them having already grown almost out of recognition. Of course, this probably means a short life and a merry one for some things which, when kept in pots, grow with less vigour and last much longer.

As has been already stated, about 500 species of plants have been planted in this house. It may be worth while to set down the names of some of the most interesting of these. Economic plants are largely represented, and it is surprising how many of these are growing with a vigour hitherto unknown when they were grown in pots in the smaller houses. The Mango is fruiting in this house for the first time at Kew. The Kaki (*Diospyros Kaki*) is ripening its orange-like fruits, and the Guavas (*Psidium Cattleianum* and *P. littoralis*) bear crops such as have not been seen at Kew before. Cottons (*Gossypium*) in variety are represented by healthy bushes 5 or 6 feet high, bearing plenty of flowers and pods; the Caricas (Pawpaws), *Passiflora edulis* and Tree Tomato (*Cyphomandra*) are also fruiting freely. The last-named plant has grown in three months from 2 feet in height to 9 feet, and its handsome cordate leaves are 16 inches across. Other interesting and important economic plants in this house are:—Cinchonas, Nepheliums (Litchi and Longan), *Persea gratissima*, Shaddock, Lemon and others of the Orange family, *Musa Cavendishii*, and others; *Lucuma deliciosa*, Mexican Apple (*Casimiroa edulis*), Sugar-cane, Uva-grass, Pomegranate, Kafir Plum, Dragon's-blood (*Dracæna*), Frangipani, Star-apple, Sea-side Grape (*Coccoloba unifera*), &c. In all, there are about fifty of the most important economic plants represented.

The selection of plants that deserve prominence at Kew is equally representative. We noted *Greyia*, *Oldenburgia*, *Gardenia Thunbergii*, *Bauhinia Galpini*, *Erythrina tomentosa*, *E. caffra* and *E. Humei*, *Burchellia capensis*, *Mackaya*, *Alberta*, *Strelitzias*, *Leucodendron* (Silver-tree), *Calodendron*, *Protea*, &c., among the African denizens. Many of these have either flowered already, or promise to do so shortly. *Erythrina tomentosa* is an extraordinary plant, with a wiry stem 4 feet high, and a head of grey-green trifoliate leaves, each leaflet measuring over a foot in width. *Malhania erythroxylon*, an interesting Sterculiad peculiar to St. Helena; *Juania australis*, a Palm found only in Juan Fernandez; *Benanthera coccinea* the scendant Chinese Orchid; *Sophora chrysophylla*, from the Sandwich Islands; and *Ipomoea Wolcottiana*, a tree-like species from Mexico, are rarities which find a congenial home in this house. *Hibiscus Manihot* is a plant which has completely outgrown its botanical character

since it was placed in this house, its leaves being 18 inches across, and its flowers enormous yellow cups. A figure of a variety of *H. Manihot* will appear shortly in these pages. A select dozen species of *Eucalyptus* form a feature along the side-beds, whilst through

Bull's-horn *Acacias*, *Calliandra*, *Cacti*, *Puyas*, *Gustavias*, *Bougainvilleas*, *Coccolobas*, *Dasy-lirions*, *Yuccas* and various *Palms* representing the flora of Mexico and the West. The collection is one that should prove of considerable value horticulturally and botanically. The

such plants as *Hymenocallis*, *Ornithoglossum*, *Begonias*, *Streptocarpus*, *Browallias*, *Chlorophytums*, and an elegant little *Sugar-cane* known as the Japanese variety.

It is intended to proceed at once with the erection of the house on the north side of the

FIG. 71.—A RASPBERRY-BLACKBERRY HYBRID: IN COLOUR PURPLISH-BLACK, WITH A SILVERY BLOOM. (SEE P. 236.)

the middle run two rows of tall plants of *Cocos plumosa*; these will no doubt form a fine feature in a year or two; *Bauhinias*, *Melastomads*, *Gordonia anomala*, *Lagerstrœmias*, *Poinciana regia*, *Roupalas*, *Aralias*, *Musæ*, *Bamboos*, and *Ficuses* are choice plants from Eastern regions; *Barnadesia*, *Blakea*, *Laeculia gratissima*, *Pogonopus caracasana*,

climbers are equally choice, among them being *Aristolochias*, *Beaumontias*, *Passifloras*, *Solan-dras*, *Cephalandras*, *Sicana odorifera*, *Lonicera Hildebrandi*, *Momordica cochin-chinensis*, &c. Among the rocks at the south end are various *Aloes*, *Agaves*, *Euphorbias*, *Cereus giganteus*, large specimen of *Opuntias*, *Sansevierias*, *Pro-teas*, *Crassulas*, &c. The undergrowth consists of

block, a vote on account for the purpose having been already taken. This house will be devoted to the cultivation of such plants as require only protection from severe weather, such as *Himalayan Rhododendrons*, *Camellias*, &c. When this addition has been finished, the whole block or range will be without an equal. It will, in fact, be worthy of Kew.

A RASPBERRY-BLACKBERRY.—The efforts of hybridists in this country and the United States of America have frequently been directed to crossing *Rubus Idæus*, the Raspberry, with *R. fruticosus*, the Blackberry, and *R. trivialis*, the American Dewberry, the prominent idea of the cross-breeder being the obtaining of a plant which, while affording a longer succession of fruit than the Raspberry, and in that respect resembling the Blackberry, would be superior to the latter in the matter of flavour. Messrs. JAMES VEITCH & SONS (Limited) of the Royal Exotic Nursery, Chelsea, showed at the Royal Horticultural Society's meeting at the Drill Hall, James Street, Westminster, on Sept. 17, a quantity of fruiting-stems of a cross which they had obtained at their Langley Nurseries between Raspberry Belle de Fontenay and the common Blackberry, the Raspberry being the seed-parent. The fruits of a purplish-black colour, with a grey bloom on them, were of the size shown in our illustration (fig. 71, p. 235), and very abundantly produced.

APPLE CROP IN THE UNITED STATES.—According to the very latest trustworthy reports, there are very few extensive Apple-producing States whose reported condition indicate more than one-half or three-fourths of a normal crop, and generally the indication is towards the lower rather than the higher average. New York reporting 58, Pennsylvania 52, Ohio 35, Michigan 38, and Indiana 56 per cent. The most favourable reports, by comparison with the foregoing, are Virginia 65, Tennessee 68, Kentucky 67, Illinois 85, Iowa 78, Missouri 76 per cent. Not only is the yield much below the average, but except in a few States, the quality of the fruit is decidedly inferior.

ORLEANS.—A horticultural exhibition takes place at this city on the days 6th, 7th, 8th, 9th, and 10th of November next, the exhibits consisting of Chrysanthemums, fruit, wine, and liqueurs. The schedule is obtainable from the Horticultural Society of Orleans and Loiret.

IMPORT DUTY ON FRUIT IN THE UNITED STATES OF AMERICA.—Uncle Sam has placed the duty on fruits as follows:—Apples, Peaches, Quinces, Cherries, Plums, and Pears, green or ripe, 25 cents per bushel; Apples, Peaches, Pears, and edible fruits, including berries, when dried, desiccated evaporated or prepared in any manner, not specially provided in this Act, 2 cents per pound; berries, edible, in their natural condition, 1 cent per quart. Currants 2 cents a pound; Grapes 20 cents per cubic foot of capacity; Plums 2 cents a pound.

CANADIAN TOMATOS.—From the English market reports it would appear that this fruit can be exported profitably in cold storage. *The Fruit Grower*, London, dated July 22, quotes Guernsey Tomatos at from 6 to 10 cents a pound, and speaks of the supply as being abundant. When we consider that this fruit often sells as low as $\frac{1}{2}$ cent per pound in this country, it is evident that we are encouraged to attempt its export.

THE EUROPEAN FRUIT CROP is estimated as follows:—Apples, England, fourth crop, will require large importations; France, light crop in the south, fair crop in the north, can export some; Belgium, third crop; Holland, fair crop; Germany, fair; Italy, good. Pears: England, worst crop for many years; France, good crop of late kinds; Germany, good crop of ordinary fruit.

THE BURBANK PLUM is a magnificent success in the Niagara district so far as growth of tree and productiveness is concerned. Mr. L. L. HAGAR of Grimsby, has some young trees breaking to the ground with ropes of this beautiful Japan variety. Mr. HAGAR believes that it will prove an excellent acquisition. *Extracted from No. IX of the Canadian Horticulturist.*

THE DUTCH NATIONAL CHRYSANTHEMUM SOCIETY, as the secretary, M. J. K. BUDDE, informs us, will hold its first exhibition of these flowers from November 12 to 16 next, in the King's Hall of "Natura Artis Magistra," at Amsterdam. The schedule is divided into three sections, viz., one for

nurserymen, another for amateurs, and a third for amateurs who do not employ a gardener. For the nineteen numbers a sum of about £100 prize-money is set apart. As there is a great rivalry among Chrysanthemum-cultivators, it is thought that this show will be worth seeing.

NEWCASTLE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.—The first meeting of the sixth session of this society was held at 25, Westgate Road, on Tuesday, September 14. The Chairman, Mr. J. BULLOCK read a very interesting paper on "Filmy Ferns," and was followed by a discussion in which many of the members took part.

SHIRLEY AND SURROUNDING DISTRICTS GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT ASSOCIATION.—The monthly meeting of the above Society was held at the Parish Room, Shirley, Southampton, on Monday, Sept. 20, Mr. B. LADHAMS, F.R.H.S., presiding over a good attendance of the members. There was an exhibition of Vegetables, and a discussion on the exhibits. There was also a good display of cut-blossoms of Dahlias, and herbaceous plants; also of fruit and Tomatos. The Annual Excursion of the members will be on October 2, to the Crystal Palace, when it is hoped there will be a good number of the members present.

SWEET-PEA SHOWS.—As yet, a special show of Sweet Peas is unknown in this country, but there is no reason that we know of why we should not have them. The flowers are very pretty and fragrant, and their development is considerably influenced by treatment. We read of a fine annual show of this sort being held in August at Springfield, Massachusetts, the majority of exhibitors being amateurs. We read of the Sweet Peas shown by Mr. ELDBRED being "superb," of "wonderful size," his fifty of Aurora "the wonder of all beholders." Although home-raised varieties were among the winning collections, these contained likewise many of ECKFORD'S. So that at the least, in the matter of Sweet Peas, we are not played out as yet.

THE ULSTER HORTICULTURAL SOCIETY will hold its exhibition of Chrysanthemums on Nov. 16 and 17, at Belfast, and, judging from the schedule now to hand, the event should be of first-rate importance. One hundred pounds and three Medals are offered in one class, which is to commemorate the Diamond Jubilee Year, and calls for forty-eight Japanese blooms in at least thirty-six varieties, open to the United Kingdom, exclusive of nurserymen. A 1st prize of £40 and a Gold Medal, with six other prizes, can hardly fail to make this competition a memorable one. Apart from the class noticed, the schedule is very similar to that of most first-class societies, and includes sections for amateurs who keep gardeners, and for amateurs who do not; also for nurserymen, farmers and cottagers respectively. The section devoted to plants seems very complete. Fruit and other miscellaneous produce is solicited.

DUTCH HORTICULTURAL AND BOTANICAL SOCIETY.—On the occasion of the meeting of the Floral Committee of this Society on Sept. 11, the committee awarded First-class Certificates to Messrs. C. Ottolander & Son of Apeldoorn, for *Abies concolor fastigiata*, *Aucuba japonica longifolia dentata*, and *Pseudotsuga Douglasii glauca pendula*; to Mr. C. G. van Tubergen, Jun., of Haarlem, for Cactus Dahlia Harry Stredwick; to Messrs. J. W. Wigman & Son of Zutphen, for Cactus Dahlias Harry Stredwick and Insignis; to Mr. K. Wezenburg of Hazerswoude, for *Daphne Laureola fol. atropurpureis* and *Physalis Francheti*; to Mr. A. P. Hendriksen of Zeist, for *Pennisetum macrurum*; and to Mr. D. Keuchenius of Hoogeveen, for *Rosa Gloire de Deventer*. Certificates of Merit were awarded to Mr. Jac. P. R. Galesloot of Amsterdam, for *Callistephus sinensis aurea*; to Mr. C. H. B. Alsche of Velp, for *Medeola asparagoides*; to Mr. G. T. Hemerik of Leiden, for Cactus Dahlia Beatrice, and Dahlia Mahala Sheriff; to Mr. C. G. van Tubergen, Jun., of Haarlem, for Cactus Dahlias Beatrice and Miss Webster; to Mr. W. van Veen of Leiden, for Cactus

Dahlia Beatrice; and to Messrs. J. W. Wigman & Son of Zutphen, for Cactus Dahlias Miss Webb, Crimson King, Green's Gem, Jessie, Mrs. Allhu and Princess Ena. Certificates of Merit were further awarded to Messrs. Sluis Brothers of Enkhuizen, Beans Hollandsche White Giant; and to Mr. Wulfscbe of Zwijndrecht, for a collection of Tom in fourteen varieties. H. C. ZWART, Secretary.

THE ANNUAL DINNER of the United Horticultural Provident and Benefit Society has been fixed for Tuesday, October 12. It will take place in the Holborn Restaurant, and Mr. H. B. MAY, of the Edmonton Nurseries, will take the chair.

CALIFORNIAN ORANGES.—The American liner *St. Paul*, which arrived at Southampton on Wednesday, Sept. 22, brought 4403 packages of California fruit, consigned to Messrs. GARCIA, JACOBS & Co. Covent Garden. The *St. Paul* docked at 10 o'clock in the morning, the fruit was discharged, loaded in railway-vans, forwarded to London, and delivered at Covent Garden Market by 7 o'clock in the evening, nine hours after the steamer docked at Southampton and seven days four hours after leaving New York. The fruit reached market in splendid condition, and all of it was sold before 1 o'clock yesterday afternoon. *Morning Leader*, September 24.

DUNDEE JAM TRADE.—In consequence of a shortage in the Scottish fruit-crop, Dundee jam manufacturers have had to resort largely to the Continent for their supplies. The changeable nature of the season wrought serious havoc with the fruit trade, severe frosts in the latter end of May doing much mischief. Apart from Apples and Pears, which have also been imported in increased quantities, there have been conveyed direct to Dundee from the Continent up to the present time, 70 tons of Gooseberries, 50 tons of Raspberries and Strawberries, 60 tons of Currants, 45 tons of Plums, and 500 baskets of Cherries. Up to the same date last year the quantities were 18 tons of Gooseberries, 15 cwt. of Raspberries and Strawberries, 10 tons of Currants, 2 tons of Plums, and 127 baskets of Cherries. A considerable portion of the Dundee jam-manufacturers' supplies landed at Leith and Grangemouth.

FLOWERING OF AGAVE AMERICANA.—There are two plants of this species of Agave now in flower in the gardens of the Right Hon. Lord FIELD, Bakeham, Englefield Green, Egham. Each spike is 22 feet high, and they have been growing since February last. Mr. WREN, Lord FIELD'S gardener, will be pleased to show the plants to anyone who is desirous of seeing them.

THE EPIDEMIC OF TYPHOID AT MAIDSTONE.—Messrs. GEORGE BUNYARD & Co. desire us to state that their nurseries are 2 miles from the town, and in no way connected with it by drainage or water supply. Visitors should travel by the London, Chatham & Dover line to Barming station, which is in the nursery.

SERIOUS ACCIDENT TO MR. WILL TAYLER.—When out driving on Saturday last, September 19, Mr. WILL TAYLER, the well-known fruit-tree Rose-grower, Osborne Nursery, Hampton, was thrown from his trap, and received severe injuries to the head, rendering him insensible for some time. His condition is extremely serious, his many friends will be glad to know that strong hopes are entertained of his ultimate recovery.

PUBLICATIONS RECEIVED.—*Journal of the Japanese Horticultural Society*, April, 1897 (Tokio). *The Water-Garden*, by WILLIAM TRICKER (New York: A. T. DE LA MARE Printing and Publishing Co.). Treating of ponds, adapting natural stream planting, seed-saving, propagation, building aqueducts, with cultural directions for all ornamental aquatics.—*The Journal of the Board of Agriculture*, September, 1897. (Loughton & Co., 1, Essex Street, Strand, W.C.) Price 1s. Excellent illustrated article on injurious insects, viz., Asparagus-beetle, Pear Apple-blossom Weevil, The Y. Moth, damaging Clover, Peas, Rape, Turnips, and Cabbage.

blight of Gooseberry (*Microsphaera groenlandica*) is also described, and the preventive remedies indicated. The number contains much interesting matter on foreign and colonial agriculture, &c.—*The Botanical Magazine of Japan* for August, 1897, No. 126, vol. xv. (Tokyo).—*Tropical Agriculturist* (Colombo), A. M. & J. FENARSON.—*Queensland Agricultural Journal*

SPIRÆA MILLEFOLIUM.

THIS may not be one of the most attractive of the Spiræas, but it is undoubtedly one of the most remarkable and interesting species belonging to that extensive genus (fig. 72). The flowers are produced in a terminal, compound raceme, 5 or 6 inches high, and each flower is about half an inch across and white. The striking character of the shrub is not so much due to flowers as to the foliage. The leaves are 3 inches long, bipinnate, and resemble very much in their minute sub-division those of the Milfoil of our waysides. The upper side of the leaf is greyish-green and glabrous, but beneath is covered with a dark-coloured tomentum, and the petioles, midribs, as well as the whole of the young wood, are covered with a very viscid gum. According to Nicholson's *Dictionary of Gardening*, this Spiræa was introduced from California in 1880, and is a low evergreen shrub. At Kew, it is a bush 4 to 5 feet high, with erect branches, and although it is never without a few leaves even in midwinter, they are then confined to the extreme tips of the shoots. Coming from California, it requires as much sunlight as is possible in our climate, but it should be given a soil of only moderate richness, for a too vigorous and succulent growth is apt to be injured by frost in winter. W. J. B.

HOME CORRESPONDENCE.

LADY HUTT VINE.—Notwithstanding the statements of your correspondent "A. D." on p. 204, I greatly doubt if the fruit of this variety will ever become popular, owing chiefly to the greenish hue of the berries to which he alludes. I have the Vine as grown on its own roots, and inarched on a Lady Downes' Seedling, and in neither case was it satisfactory, the berries being small, although the bunches were large, was the flavour not good. These Vines were growing in inside borders with access to a well-made border outside. In the same vinery there grew side by side with Lady Hutt a Vine of Appley Towers, which was everything that one could desire, being large in berry and bunch, and a heavy cropper. The fruit was often exhibited at important horticultural shows, and always obtained 1st prizes. This Vine of Appley Towers was inarched on another of Lady Downes', and was pruned on the spur method; although I, like Mr. Bowerman, have an idea that the fruit would be better if taken from long rods. It is one of the best varieties for hanging till late in the season. H. T. M.

CAULIFLOWERS FORMING HEADS A SECOND TIME.—It is a common thing for Veitch's Extra Early Forcing Cauliflower to throw out sprouts from the side; and the same kind of second crop has occurred in my garden with the Walcheren, which had sprouts 1 inch in diameter at the base, and heads as large as an ordinary tea saucer. We obtain a useful crop of small Cabbages after the first cutting, and why not Cauliflowers? Only let the land be in good heart,

FIG. 72.—SPIRÆA MILLEFOLIUM: FLOWERS WHITE.

July, 1897, vol. i., part 1. (Brisbane: EDMUND GARGOY, Government Printer.)—*The Agricultural Journal* (Cape of Good Hope), August 19, 1897.—*Botanische Zeitung*, Heft ix., September 16.—*Botanische Centralblatt*, Band lxxi., Nos. 12 and 13.—*Die Natürlichen Pflanzenfamilien*, No. 159, Sphaerales and Laboulbemiæ, by G. LINDAU.—*Die Gartenwelt*, with supplementary coloured plate of Chrysanthemum

Systematik Pflanzengeschichte und Pflanzengeographie, vol. xxiii., No. V., and vol. xxiv., No. II.—*Agricultural Gazette of New South Wales* for July. Articles on Useful Australian Plants, giving vernacular, botanical, and aboriginal names; on the Sheep Fluke, Orchard notes for August, Vegetable and Flower Culture, besides much that is more peculiarly agricultural in its nature.

and the planting done early, and not too close, to reap the best results. *A. Smith, Harewood House Gardens, Hendon, N.W.* [We have several communications from gardeners in various parts of the country to the same effect. ED.]

HAMPTON COURT GARDENS.—Oliver Wendell Holmes, says that:—

"Little of all we value here,
Wakes on the morn of its hundredth year
Without both feeling and looking queer!"

The distinguished author makes exception, however, in the interests of a tree and a truth. The famous Vine here allows that he was right. In its hundredth and twenty-ninth year it shows no decay. At the present time it bears a crop of no fewer than 1,200 bunches of Black Hamburgh Grapes—about two-thirds having been removed in the thinning process. Probably, the Vine is the oldest in existence under cultivation. All its fruit is forwarded to the Royal Household via Windsor, and the last bunches will not find their way to the Royal table until about December. What is called the Jubilee Bed here is a splendid design, and has been worked out with great taste and skill by the Garden Superintendent, Mr. Gardiner. It is one of the largest oblong beds just opposite the Tennis Court. The groundwork consists of *Herniaria glabra*, and in the centre is a large diamond (indicative of the Diamond Jubilee); the centre consisting of *Echeveria Peacocki*, and is surrounded, to complete the diamond, with a broad margin of red *Alternanthera*. At either end is a large crown worked out with red and yellow *Alternantheras*; and at the sides, in red, are the monographs of the Queen, the Duke of York, and Prince Edward of York. *J. B.*

EARWIGS.—If Mr. Aggett will lay two boards on the ground, or sloping against a rest, with a small space between them, he will find that he can catch thousands, and may practically exterminate his earwigs. In a similar way woodlice may be caught very easily. In the Cactus-house, my foreman, Mr. Lamb, found that by laying pieces of bark together, large numbers were secured. *R. J. Lynch.*

—In reply to your enquiry in reference to my note in last week's issue, the earwigs were not troublesome, and did not touch the plants after the watering was discontinued, and my experience is, that the critical time is when they are put out, and until the growth becomes somewhat rank, when they leave them strictly alone. *W. H. A.*

EXPERIENCES WITH HORTICULTURAL BOILERS.—Of these my experience embraces only three kinds, namely, the upright tubular, the Cornish-Trentham, and the saddle. My first experience was with an upright tubular, which required a specially prepared stoke-hole, having a top platform to hold a store of fuel from which the boiler was fed, the ashes being withdrawn from the ash-pit at a lower level. Two of these boilers were fixed near their work, having a long under-ground flue to convey the smoke to an upright chimney-stack. These went on very well for a number of years, the underground flue, however, giving me a good deal of trouble. The Trentham-Cornish boiler about this time made its appearance, and was hailed at the time as presenting a panacea for the boiler difficulties. I got two 7 feet long, and had them placed side by side in a capacious stoke-hole, just under the chimney-stack; did away with the old underground flue, building in its stead a tunnel sufficiently large in which to place a flow and return-pipe, and in which a man can pass comfortably along to examine and repair those pipes at any time, should they require it. All the houses right and left are served from off these mains in the tunnel. By this arrangement we secured a far better draught for the boilers, and the flow and return-pipes follow the line along which previously the smoke used to pass. This arrangement worked very well until we were overtaken by a series of wet years—those years which played havoc with many tenant-farmers, and killed many of the finer feeding grames in the pastures. The water rose in our stoke-holes, necessitating almost constant pumping; and this was rendered all the more necessary on account of the retiring flue belonging to the Trentham boiler passing along the bottom or floor-level of the stoke-hole. These boilers, having worked for some considerable length of time, began to show signs of decay, and I therefore took an early opportunity to take them out, and raise the floor of the stoke-hole 3 feet, and since doing that we have had no more water rising through the bottom. Being desirous of obtaining a boiler more simple in its construction than the Trentham, and equally powerful,

I called in a local firm. They gave me a 7-foot saddle-boiler, with four crossed Galloway tubes at the far end, two flow-pipes fixed on the top instead of one only as is generally put. Finding with the Trentham boilers always great difficulty in getting at the far end to clean them out, I determined to obviate this in the setting of my new saddles, and this was rendered all the more necessary on account of the Galloway tubes. To this end, therefore, instead of fixing the ends of the boilers both up against the wall of the stoke-hole in the usual way, I had them set 4 feet away from it, thus leaving a passage all round behind, fixing at the back end of each boiler a heavy furnace-door lined with a substantial fire-brick slab; this enabled us easily and thoroughly to clean out the far end, which could but imperfectly be done from the front. These boilers are furnished with "sludge" doors, by which they can readily be cleaned out. I have preserved the furnace-door or mouthpiece of the Trentham boilers, which I thought were good ones. The ash-pits of these boilers are all made hollow and water-tight, thus able to hold water, the object of this being to prevent the destruction of the fire-bars, which had been, but which now seldom occurs, a constant source of expense. All our other boilers and stokeholes have in turn been treated in a similar manner. Fortunately the stokeholes had been made originally very roomy, and all of them are well ventilated. The entrance to our largest stokehole is by an inclined tunnel, being much safer than by a flight of steep steps. I am not aware that anyone has tried this manner of setting a boiler, though I have shown it to many gardeners who have called here. *W. Miller, Combe Abbey Gardens.*

BUSH BOUGAINVILLEAS.—Does the growing of *Bougainvillea glabra* in hard spurred bush-form in pots, and in a cool temperature, materially tend to deepen the colour of the bracts? There are two large sturdy bush-plants in pots at Hackwood Park in fine bloom treated as mentioned, and when I saw them the other day I could but remark how exceedingly the bract colour resembled that seen on Mr. Cypher's fine plant exhibited at Shrewsbury, which he has named *Cypheri*. Another person had previously noted the same thing. *B. glabra*, growing in more warmth, close under the roof, had very pale bracts in comparison. If the form of treatment mentioned is not responsible for the deepening of the floral colour, then are the two plants at Hackwood a distinct and beautiful variety. *A. D.*

FIGS, BROWN TURKEY AND OTHERS.—It is doubtful whether, as an out-of-doors Fig, we have a better and more useful variety than Brown Turkey. In the Isle of Thanet, Figs grow in the open with great freedom and productiveness, and need but little care and attention. At Northdown, there are several trees growing at the foot of walls near to hard gravel and asphalt footpaths, and under which the roots run, so that feeding or top-dressing is an impossibility; yet these trees bear heavy crops annually. No pruning is practised more than to remove straggling branches, to keep the trees within reasonable bounds. The soil is of a very chalky nature. The next best variety is Brunswick, and the fruits attain a large size, but are not so high in quality, although these monstrous fruits tell upon the exhibition table. Other dark-fruited varieties have been tried in different gardens, but have not proved equal to the kind mentioned above. White Marseilles is the only white one growing here, and although growing by the side of the others it is much less fruitful. This season we have had a very fair crop, and the fruits are delicious. They have ripened well owing to the hot, dry season we have had; but the trees are inclined to grow too strongly to be fruitful. *H. Markham, Northdown, Margate.*

THE BRUSSELS EXHIBITION.—From what I can learn, very few people have been over to see the exhibition at Brussels this year from England. I think it would repay many horticulturists to do so, because they would no doubt break their journey on the way home at Ghent, and there they would, if they elected to do so, see the immense strides that are being made in the erection of houses, and the improvements in the forms that they have found to be advantageous. I will, with your permission, enumerate a few of these. The staging consists of iron standards, and on these are screwed or riveted bars of T-iron, or angle-iron; then they take thin boards and place them on the before-mentioned T-iron bars; on this, wire-netting slightly turned up at the sides and at the end, is put, and it appeared to be made in lengths of about 10 feet. On to this wire-netting, cement and sand, mixed together with

water, are well rubbed in and smoothed down, and before it is quite dry holes are pierced in it to afford egress for the water; and when it has set sufficiently hard, the boards are withdrawn from under the wire-netting. This leaves a perfectly rigid staging that one can walk upon without any fear of its collapsing or cracking. A wide staging of this sort is placed in the centre, and two narrower ones on either side of the house. Another improvement which has been dictated by experience is to carry a hot-water pipe about 7 feet high the whole length of the house on either side, and, say, one-third of the distance across. The advantage of this is that in place of the cold air coming down from the lower part of the roof in frosty weather, a genial temperature is maintained thereabouts instead; which is not obtained if there are only hot pipes underneath in the old-fashioned style close to the floor. Water being a prime necessity in Belgium, they find that they can get constant service at Brussels and Bruges by the use of the Airmotors, and many contracts for these apparatus are given out. They are also finding out the great advantage of pumping by these machines into a tank carefully erected over a shed, well supported by the walls of the building, and letting the water reach their houses by gravitation. When the tank is built in under the roof the water rarely ever freezes. I made several journeys in different directions on the roads running outside these towns, and the number of glass-houses, and the acres of ground being covered by them, would surprise anyone who had not seen these towns for two or three years. Further than this, they put up a large central house, and around this central house they take care to have plenty of space for extending it. Houses are then built at right angles to this one, with all the doors opening out of this central house, so that in cold weather, when these doors are opened, no current of cold air enters the house. In all these new houses every precaution is taken to catch the rain-water, and lead it into enormous tanks. The quantities of *Asclepias indica* at the present time in the gardens point to the fact of the prices tumbling very rapidly if cold weather sets in. There have already been one or two sharp frosts, and many of the cultivators admit that it will be impossible for them to save their stock of plants if they do not get a little more time before the winter sets in, in earnest, or they must be prepared to accept very low prices. The plants that I saw were in splendid condition. Great improvements have been made in the heating arrangements; anthracite coal is now burnt, and they have learnt by experience the necessity of having high chimneys, and where they have not got the convenience of using bricks, large chimneys similarly constructed to the American style of factory-chimney, and made of sheet-iron, are erected. *Thos. Christy.*

THE ROSARY.

SOME NEW CONTINENTAL ROSES.

Emmanuel Geibel, Kiedlung, Lubeck.—The flowers of this admired novelty, now some years in commerce, are large, full, and very beautiful. In colour it resembles *Madame Falcot*. A fine variety for the open ground.

Gudrum, P. Jacobs, Wertendorf, is a hybrid Tea of the form of *Perle des Jardins*. The plant is extremely floriferous, every shoot carrying several flowers on long strong stalks. The colour is a glistening silvery rose-pink with a light fiery-red centre.

Louise Müller is a cross between a seedling of *Pierre Notting* and *Safrano*, and one of General Jacqueminot and *Emperor of Morocco*. It possesses the property of flowering from the beginning of June to the first autumnal frost without cessation. The colour of the flower is a lively shade of red. It is useful also as a climber.

Coronet, Dingee, Conard & Co.—This novelty was obtained by crossing Paul Neyron with *Bon Silene*. It is a magnificent, very full rose-pink, with a silvery tinge in the centre. The buds are dark-carmine. The plant is similar to Paul Neyron in habit, and it blooms early and continuously.

Mr. D. Lambert of Trèves has succeeded in obtaining a cross between *Rosa polyantha Aglaia* and *Turner's Crimson Rambler*. The progeny is said to possess very fine foliage, great floriferousness, and very full blooms of a tender hue. *Illustrations Garten Zeitung.*

In the *Journal des Roses* we read of a *Maréchal Nial* de M. Perny, which, according to the competent opinion of M. P. Cochet, will turn out to be a wonderfully useful Rose for the bouquet-maker. It is said to have been derived from the *Maréchal*, but it differs in colour from that variety, being rose, and sometimes changing to red. The expanded flowers have a diameter of 5 inches.

PLANT NOTES.

SCUTELLARIA MOCINIANA.

THIS is one of our most beautiful flowering stove-plants. It is a native of Mexico, and was introduced to this country in 1868. When arranged between pots of Maidenhair Fern, its bright scarlet flowers produce a pleasing effect. It is propagated by cuttings taken in the spring, and placed singly in small 60-pots in a temperature of 65°. The cuttings should be shifted into 48's when well rooted, using a compost consisting of one-half loam and one of leaf-soil, with a little sand added. By judicious pinching, nice, bushy plants, with many spikes of flowers, can be grown in this sized pot.

MORSA ROBINSONIANA IN CALIFORNIA.

This handsome Iridaceous plant, native of Lord Howe's Island, has been flowering beautifully in the garden of Mr. Geo. P. Rixford, secretary of the Californian Academy of Sciences, San Francisco, this summer. It was raised from seed sent by the late Baron von Mueller, in 1881, and this is the first time that it has flowered in California. The flowers are rather large, white with dark centres, and borne in spikes. Benthams says of this species that it is "known as the Wedding Flower. It is the largest species of the genus; the habit is that of the nearly-allied *Pardanthus chinensis*, the flowers are nearly those of the *Morssia iridioides*." *J. Burt Davy, Berkeley, California, September 3, 1897.*

LAW NOTES.

THEFT OF MUSHROOMS AT BECCLES.

WILLIAM CHILVERS, Leonard Betts, Benjamin Ward, and Henry Pitchers, Beccles boys, were charged with stealing Mushrooms, value 2s., the property of Mr. J. Edwin Crisp, at Homefield, on the 5th inst. Mr. J. P. Larkman appeared for the prosecution, and said this case was one of stealing cultivated Mushrooms, and he should be able to call witnesses to prove cultivation without any doubt.

Mr. J. E. Crisp said he was the owner and occupier of the house and grounds known as Homefield. Part of his grounds consisted of enclosed land adjoining the house, and extending down to St. Mary's Road. The land was ordinary arable land before he laid it down, and he gave orders to have it planted with Mushroom spawn. This was done by Robert Moore, his gardener at the time. Since then he has had good crops of Mushrooms—the crops varying, of course, with the weather. Lately he had missed Mushrooms; there had been plenty in the evening, and none in the morning. In consequence he communicated with Inspector Lingley.

Robert Moore, gardener at Belstead Hall, near Ipswich, said he was formerly gardener to Mr. Crisp, and while in his employ received orders to sow Mushroom-spawn on the lawn, which he did. By the Bench: He sowed the spawn seven or eight years ago. By Mr. Larkman: When once sown the spawn would go on increasing by itself. It was not necessary to sow it annually.

Police-constable H. Churchyard said he was on duty on Sunday morning in Mr. Crisp's park. About 4.30 he saw the four defendants come from St. Mary's Road into the park, spread themselves out about 20 yards apart, and go round the park gathering Mushrooms. They had a basket (produced) to put them in. He saw all the boys gather Mushrooms.

Chilvers said they did not go inside the park; they went on the lawn.

Witnesses said the boys did not go where the deer were.

The Bench retired, and on their return the Chairman said they were all convicted, and would be fined 7s. 6d. each, in default seven days. A fortnight was allowed to pay. Ward paid at once. *East Suffolk Gazette.*

INFERIOR MANURE.

At Lichfield, Wednesday, September 22, Margaret Catherine Ginster, Frank Ginster, and Rudolph Ginster, trading as M. C. Ginster & Sons, patent manure manufacturers, Erdington, Birmingham, were charged at the instance of the Staffordshire County Council with breaches of the Fertilisers and Feeding Stuffs Act, 1893, by having failed to supply invoices and details of analysis with two loads of turnip-manure purchased by Mr. Nigel C. A. Neville, stipendiary magistrate of Wolverhampton, for use on his farm at Shenstone in June and July last. Mr. Fisher prosecuted on behalf of the county council, and Mr. Vachell appeared for the defence. The manure purchased was advertised to contain fish-blood, horn-hoofs, flesh, bones, and other animal-matter, with a trace of flour, of which some were dissolved and some undissolved, some partly soluble and some insoluble, because, if manufactured all soluble, it would be too rich for the first crop, the aim being to grow two crops without the assistance of stable-manure. The manure was sold at from £6 10s. to £7 10s., and Mr. Neville purchased two and a half tons in June, and half a ton in July. Not having been supplied with proper invoices and analyses, and failing to secure satisfactory results from the manure, Mr. Neville sent samples of the last load to Mr. E. W. T. Jones, the county analyst of Staffordshire. That gentleman said the manure consisted of blood and animal-matter largely mixed with shoddy, and he pronounced the samples to be rubbish, not worth more than £2 to £3 per ton. Mr. Ginster, senior, declared the manure was what it was represented to be in the advertisements. The Bench imposed a penalty of £2 and costs on each of the three members of the firm for each of the two offences, and allowed the county council £15 15s. for special costs. The full penalties and costs amounted to £33 18s. *Times, September 23, 1897.*

NURSERY NOTES.

MESSRS. JOHN LAING AND SONS.

A RECENT inspection of the fruit trees grown by this firm was suggestive of some retrospective thoughts in connection with the fruit question, and they fashioned themselves into looking back—say, to 1883—when the first famous Apple conference was held at Chiswick under the auspices of the Royal Horticultural Society, followed in later years by similar conferences under the same good lead. There is no need to question the belief that these gatherings drew increased attention to pomological matters, with the result that hardy fruit culture, if it has not advanced by leaps and bounds, is making sensible progress.

In conversation with Messrs. Laing's able manager here, Mr. Wakelin, it was gleaned that a more beautiful display of Apple blossom was never seen, but the high hopes once held of a great fruit crop were dashed by late frosts; still, there is a good sprinkling. Amongst the earlier varieties where the set was early, of course the deficiencies are not so noticeable; but amongst the late varieties which were in flower when the frost came the loss is much greater. The soil of the fruit grounds consists of a light, yellow, sandy, maiden loam. The trees are not winter-pruned, but summer-pinched. To numbers of persons who grow their trees within restricted areas, and subject them to much branch pruning, this is a point of much importance.

Regarding the important question of stocks, the adaptability of the Quince for Pears and the Paradise for Apples has been amply proved here by the mass

of roots these stocks produce on the surface, thus obtaining all the benefit of the sun's warmth, and the stimulating action from manurial mulchings and waterings. Herein, doubtless, lies the secret of the production of fine fruit both for table and exhibition. In such a nursery as this, where the demand for trees is great, one noted them grown—and grown well—in the various forms to suit the many requirements. Amongst Apples, the standards and half-standards were noticeable by reason of their straight, bright-looking stems, and good heads. Then, what a sight were the sturdy young bush-trees, 2½ to 3 feet high! The pyramid-trained trees, too, are in excellent condition—well-formed trees, with good lower boughs. Noteworthy was a very large stock of standard Apples on Crab-stock for orchards; horizontal and fan-shaped trees also arrested our attention, as did a fine batch of young Apple stocks on Crab and Paradise, and Pears on Quince, and double-worked. Cordon Apples, so useful as edgings for garden-walks, or for training to walls obliquely, are well cared for, being represented by a fine stock; the trees bear very quickly, and produce handsome fruit.

It may prove of interest to allude to some of the finer Apples grown here. Bismarck, extra-large, similar to Nonsuch, but with more colour, a great bearer, keeps well, and retains its flavour till the end of April. Potts' Seedling, very free bearing, a culinary Apple of the first quality; it forms a medium size pyramid, and does well as a standard. Lane's Prince Albert is a variety that no garden should be without, forming as it does a medium-sized bush or standard, and it is a prolific bearer. Lord Suffield is one of the very best early varieties, and a great cropper, and of which a good stock is grown. Well worthy of mention is the constant cropper Manx's Codlin, bearing when even quite young, and forming a small but very handsome pyramid on the Paradise. Lord Derby is a good orchard or garden variety, and is withal a handsome Apple, a strong grower, great bearer, and a variety of the first quality. Calville d'Été is a fine crisp fruit of medium size.

Pears, too, are well grown, being represented by a vigorous stock in all shapes—standards, half-standards, pyramids, dwarf fan-trained, and horizontal trained (for walls and espaliers), bush-trees and cordons, single, upright, and diagonal. The newest variety, Le Lectier, melting, good flavoured, and a good cropper, is worthy of mention.

There is a very fine quarter of large fruiting Peaches and Nectarines—trees with thirty and forty shoots on them. Highly worthy of special mention is the fine stock of dwarf-trained large trees of that fine Nectarine, Early Rivers, a very fine, large, and early variety, of exquisite flavour. There is also a large stock of extra sized Peaches, Nectarines, and Apricots for orchard-house culture, and another good batch of trees coming on for that same and certain method of securing a crop of fine fruit. Quite worthy of mention, too (for orchard-house culture), is a good stock of Apples, Pears, Plums, and Cherries in pots of the newer and good varieties, hardened off and well-budded.

It is not often that one sees, as at this nursery, such a stock of dwarf-trained, extra-sized Apricots. Not a sign of the dreaded canker, so often seen, but free from this scourge, and representing a clean, healthy, and vigorous stock.

The Cherry occupies an important position among our dessert fruit, not only on account of its beauty and delicious flavour, but because some of the varieties are the first to ripen of our out-of-door fruits, and, as is well known, it is also well adapted for cultivation under glass. Here Cherry-trees in all the popular sorts may be seen in all shapes for training or otherwise. Likewise noteworthy are the Cordons, pyramids and standards. We noticed a good and healthy batch of *Cerasus Mahaleb*, the stock that all the Duke Cherries are worked upon. After Apples, the most profitable crop to grow is unquestionably Plums, and here is grown a fine stock of the best varieties, and in the various forms of tree required to bring about the most satisfactory by would-be cultivators.

A general collection of hardy ornamental trees is grown here, such as Elms, Acers, Acacias, &c. The new golden-leaved Maple—*Acer aureo-variegatum*—presenting a good bit of colour, is a first-rate novelty worthy of the attention of planters. Conifers, too, and various hardy climbers are also well grown at Forest Hill.

As is well known, by the frequent and successful appearance of the firm at our leading exhibitions, the Rose is very extensively cultivated by them. Here were seen many thousands of Rose-trees and bushes. 35,000 standard Briars were being budded, and a good batch was noted of Manetti stocks and seedling Briars just budded. Of standard Roses there is a big and healthy stock, in all the popular varieties.

At the branch nursery, the main display of bedding Begonias has now been for the first time concentrated, and for which increasingly popular class of flowers the firm have deservedly gained a world-wide fame by reason of their persevering and successful work amongst them. The change of soil from Forest Hill was evidently a move in the right direction. The plants are arranged in very long beds, about 4 feet wide, representing thousands of plants, and arranged in their different colours. It is a wonderful collection, literally exposed to the four winds of heaven.

Lacking indeed of the quality of appreciation would be the visitor who could gaze, without admiration, on the Begonias found at this branch in the various structures devoted to their cultivation. We noted the following as amongst some of the best of the double-flowered varieties, and raised by the firm:—Mr. John T. Bennett-Poß: this grand variety has splendid flowers, which are beautifully fringed and Camellia-formed, of good substance, and perfectly erect; Marchioness of Downshire, a fine deep crimson, very dwarf, large, erect flowers; Lady Frederick Fitzroy, a superb yellow Apricot, excellent Camellia-formed flowers, most attractive, and should be in every collection of Begonias; Invincible, vivid crimson fine form, habit and substance extra fine; Ernest T. Cook, a splendid dark glowing crimson, large and full double flowers, one of the best in this colour; Empress Frederick, rich rosy-pink, rose-shaped flowers, superb; Cléo, a fine frilled yellow; Lady Wilton, beautiful pinky-salmon, Camellia-shaped flowers, bushy habit, extra fine; Lady Williams Wynne, a magnificent deep yellow, very large full Camellia-shaped flowers, erect habit, a splendid variety; Duchess of Northumberland, a handsome bright salmon, extra large flowers; Duke of Fife, a beautiful rosy-salmon, very large erect double flowers, distinct, good habit, floriferous.

The stock of Crotons, some of the best, showed numerous highly cultivated varieties. One noted superb ornamental-leaved Begonia, hybrids of B. Rex, of which a splendid variety is Louis Cappe, silvery satin-white leaves, rose veins surrounded with green.

In the excellent and varied collection of Ferns, we noted *Adiantum Lambertianum*, exceedingly small pinnae, with gracefully pendulous fronds; *A. Weigandi*, a very distinct kind, fronds crispy, and pinnae slightly overlapping. An acquisition, and a beautifully variegated plant, is *Bougainvillea speciosa variegata*. Another good variegated plant is *Nicotiana affinis variegata*. *Anthurium Fendleriense* was notable with its bold habit and broad foliage. *Cissus argentea* is uncommon, and *Cyanophyllum magnificum* is one of the most beautiful foliage-plants in cultivation, but rarely seen nowadays.

In the outside quarters was noted a very fine collection of new and improved varieties of Cactus, Pompom, show, and single Dahlias. A mass of *Chrysanthemum maximum*. Duchess of Abercorn, was noted as a good thing with its large pure white handsome flowers. Decided acquisitions for the flower-garden are:—*Antirrhinum album floribundum*, a beautiful snow-white variety, dwarf and floriferous. A Crimson Bedder, deep crimson self, of a dwarf compact habit; a most effective variety. A Yellow Bedder, pure yellow self; is a valuable novelty. J. B.

SOCIETIES.

ROYAL HORTICULTURAL.

BRITISH-GROWN FRUITS AT THE CRYSTAL PALACE

(See also p. 234.)

Thursday, Sept. 33, and two following days.

A REALLY good show of British-grown fruits was opened at the Crystal Palace on Thursday. There may have been misgivings on the part of the management that the comparative scarcity of Apples and Pears this season, would result in a poor show. If this was the case, the fears have not been realised. It was a most satisfactory display, and in a measure, an astonishing one. Grapes as a rule were not of exceptional quality, but they were fair. Apples and Pears, however,—in fact hardy fruits, were shown abundantly, even more numerous than in last season, for we are informed that 1000 extra plates have been in requisition. The average quality throughout was high; there being but little disparity in many instances between the 1st, 2nd and 3rd prize collections. The arrangements worked smoothly, and considering the amount of work such a show throws upon the secretaries of the society, Mr. WRIGHT, the superintendent at Chiswick, and his assistant Mr. HUMPHREYS, the society's officers are entitled to congratulatory commendation.

The Schedule was composed of the following divisions:—Division I., fruits grown under glass or otherwise, open to gardeners and amateurs only, containing fifteen classes; Division II., including seven classes, open to nurserymen only; Division III., for fruits grown in the open air, nurserymen excluded, containing twenty-four classes; Division IV., for single dishes of fruit grown in the open air, nurserymen excluded, containing ninety-four classes; and Division V., composed of the Veitchian classes for flavour in Apples and Pears.

DIVISION I.

The 1st class was for twelve dishes of ripe dessert fruits, with certain restrictions as to the number of varieties of any one kind. The three competitors were Lady H. SOMERSET, Eastnor Castle, Ledbury (gr., Mr. F. Harris); The Earl of HARRINGTON, Elvaston Castle, Derby (gr., Mr. J. H. Goodacre); and Sir J. W. FRASER, Bart., Hutton Hall, Guisborough (gr., Mr. McIndoe). The prizes were awarded in the order in which we have given the names. Mr. McIndoe was less fortunate than usual, but there was no mistake made in the judging; the collection from Mr. Harris was ahead. His Grapes were Muscat of Alexandria, good large bunches but berries only indifferently coloured; and Gros Maroc. He had a good Pine-apple, a seedling Melon; Pear, Pitmaston Duchess; Apples, Ribston Pippin and King of Pippins; Peaches, Sea Eagle and Prince of Wales; Nectarine, Albert Victor; Plum, Golden Drop, and Brunswick Figs. The collection from Mr. J. H. GOODACRE contained Muscat and Black Hamburg Grapes, Pine-apple Nectarine, Brown Turkey Fig, two dishes of Plums, and one of Peaches (Sea Eagle), Pine-apple Nectarine, Hero of Lockridge Melon, Queen Pine, Pitmaston Duchess, and Souvenir du Congrès Pears, and American Mother Apple.

Mr. McIndoe's Gros Guillaume Grapes were good in bunch, but had been knocked about considerably. He had Buckland Sweetwater for the other variety. He had two dishes of Apples, two of Pears, two of Plums, and two of Peaches.

The competition for the best collection of eight dishes was limited to exhibitors who had not competed in the larger class. There were six fruit-growers in competition here, and the 1st prize was won by Mr. Geo. REYNOLDS, gr. to Messrs. De Rothschild, Gunnersbury Park, Acton, W. He had well-coloured, moderate-sized bunches of Muscat of Alexandria Grapes, and excellently-berried, but not well-coloured bunches, of Gros Maroc. A fine Melon, the fruit of a seedling; Gladstone and Princess of Wales Peaches, both very good, the latter unusually well coloured; Pine-apple Nectarine, very well coloured; Ribston Pippin Apple, and Cox's Golden Drop Plum. The 2nd prize went to Mr. W. J. ENYON, gr. to Mrs. WINGFIELD, Amptill House, Amptill. He had fine Black Alicante Grapes, three bunches of Golden Queen, an Eastnor Castle Melon, two dishes of Peaches, a good dish of Doyenné du Comice Pear, Brown Turkey Figs, and Cox's Golden Drop Plum. The 3rd prize was taken by Mr. W. TIDY, gr. to W. K. D'ARCY, Esq., Stanmore Hall, Middlesex, who included in his collection a dish of fruits of *Passiflora edulis*. The other exhibitors in this class were Mr. F. COLE, gr. to Sir Geo. RUSSELL, Bart., Swallowfield Park, Reading; Mr. SMITH, gr. to R. AVEY, Esq., Bridgemoor House, Henley-on-Thames; and Mr. W. TAYLOR, gr. to C. BAYER, Esq., Tewkesbury Lodge, Forest Hill, S.E.

Figs, one dish.—There were eleven dishes of Figs staged, the best being Brown Turkey, shown by Mr. W. Messenger, gr. to C. H. BERNERS, Esq., Woolverstone Park, Ipswich. The same variety from Mr. H. FOLKES, gr. to C. E. STRACHAN, Esq., Gaddesden Place, Hemel Hempstead, was 2nd; and Mr. W. MITCHELL, gr. to W. FLEMING, Esq., Chulworth Manor, Romsey, again with the same variety, was 3rd. None of the newer and better flavoured sorts were shown, a matter of some surprise.

Collection of Hardy Fruits not exceeding Fifty Dishes.—These fruits were grown entirely in the open, and there were three

competitors. The 1st prize was won by Mr. Geo. REYNOLDS, gr. to Earl Percy, Syon House, Brentford, with a much excellence. The Apples shown best were Pippin, Ribston Pippin, Alfriston, Lord Derby, King, Wealthy, and Cox's Orange Pippin. The Pears were good:—Doyenné Boussoch, Jean Van Gommaston Duchess, Beurré Diel, and Brown Beurré. Of these were Admirable, Barrington, Golden Eagle, W. Admirable, Sea Eagle, and Nectarine. Plums, Cox's Drop, Pond's Seedling, Wyedale, and Washington; Shropshire Prune, Morello Cherries, Filberts, Wals Hazelnuts, and a few bunches of Sweetwater Grape fruits were placed upon coloured foliage on plates, exhibit had a good effect. The 2nd prize went to Powell, gr. to Colonel BAYMER, M.P., Islington Hoe, Chester. No trouble was taken in this case to set fruits in a decorated fashion, but the quality of the Apples and Pears was very good. The collection contained dishes of Peaches, two dishes of Nuts, one of Medlar, Cox's Golden Drop Plum, and three bunches of Sea Grapes; all the rest were Apples and Pears, most of very large size. Mr. W. MILLER, gr. to Lord Foley, Lodge, Claygate, Esher, was 3rd, exhibiting Apples, also Filberts, Walnuts, Brown Turkey Figs, and Medlars.

Collection of Hardy Fruit not exceeding thirty-six dishes.—This class was intended to illustrate house culture, and might be grown partly or entirely glass. There were only two exhibitors, the 1st prize taken by Mr. R. POTTER, gr. to Sir MARK COLLET, Clero, Kensing, Sevenoaks. He had Foster's Seedling and Gros Maroc Grapes, Rondi Noir and Brown Figs, Princess of Wales and Lady Palmerston No Golden Eagle Peaches, Autumn Compote and Golden Drop Plums, and the rest were Apples. Some of the Pears were very large, fine specimen of d'Angoulême, Marie Louise d'Uccle, Boussoch, Pitmaston Duchess, Marguerite, and others were noticed. Apples, too, exhibited culture. The best were Emperor Alexander, the Ribston Pippin, Baldwin, King of Tomkins Cou, Lady Henniker. Mr. J. McINDOE was awarded 2nd and a very good collection it was. His Grapes were Hamburg, Foster's Seedling, and Gros Maroc, three of each. Peaches, Mrs. Sharpe, Champion, Golden Sea Eagle, and others; Plums, Pond's Seedling, Cox's Drop, Magnum Bonum, Late Transparent Gage, B. Green Gage, Archduke, Prince Englebert, Comice Gage, &c. His Negro Largo Figs, Apples and Pears, fine, and among the Apples we noticed the very variety James Grieve.

GRAPES.

ix distinct varieties, two bunches of each: both 1 White must be represented.—Mr. REYNOLDS, gr. to M. Rothschild, Gunnersbury Park, Acton, won well the position here, with three black and three white: the former being Black Hamburg, well kept and colour; Gros Maroc, fine in berry and colour; Ni Court, well finished; and of the latter well-coloured bunches of Muscat of Alexandria, specially fine; Napoleon, clear in berry and well-coloured; a examples of Buckland Sweetwater. Mr. TAYLOR, BAYER, Esq., Tewkesbury Lodge, Forest Hill, S.E. a good 2nd, his best being very fine Madresfield Co in berry and well finished; good Muscats, fine Gros and Gros Maroc, with Gros Guillaume. Mr. GOODACRE, Earl of HARRINGTON, Elvaston Castle, Derby, belt 3rd, he staging well-finished bunches, the best being Pearson, extra fine in bunch and berry; Mrs. Pin Black Hamburg and Muscats.

For three varieties Grapes, distinct, two bunches 1 Mr. COLE, gr. to Sir Geo. RUSSELL, Bart., M.P., Sw Park, Reading, was easily first with splendidly Muscated, very clear in the berry; good Alicante and Seedling, both well finished. Mr. JONES, Ridgway Cradley, Malvern, came 2nd with Gros Maroc, Gros and Alicante, all well coloured medium-sized bunches. Harris, gr. to Lady HENRY SOMERSET, Ledbury, his best being Muscated and Gros Colmar, which close, if not superior to the 2nd.

For three bunches, Black Hamburg.—Mr. MITCHELL, J. W. FLEMING, Esq., Chilworth Manor, Romsey, to the front with large bunches, very fine in the superbly coloured. Mr. TAYLOR was a good 2nd lacking colour, and Mr. REYNOLDS 3rd.

For three bunches, Madresfield Court.—Mr. TAYLOR his exhibit being excellent, very fine in berry coloured. Mr. W. TIDY, gr. to W. K. D'ARCY, Esq., more Hall following, his Grapes all lacking colour, gr. to Mrs. WINGFIELD, Amptill House, a good 3rd.

For three bunches Gros Colmar, or Gros Maroc, Mr. won with the former, the fruit being fine, the bunches were the berries; Mr. REYNOLDS followed with Gros Maroc, showing large bunches; Mr. COLE being the last-named variety.

For three bunches Alicante, Mr. F. COLE was 1st, with well proportioned, and the colour good; Mr. J. BUSHAM, Vineries, 1st, showing well for 2nd p How, gr. to HENRY TATE, Esq., Park Hill, S. Common, followed, exceedingly close, with bunches of the three.

For Three Bunches Lady Down.—Mr. TIDY was place with well finished bunches of medium size, son following with a good exhibit; Mr. KEMP, gr. SCRABE DICKENS, Esq., Chulworth Manor, Romsey, prize.

For Three Bunches of any other Black Grapes. Mr. MITCHELL won easily with beautiful examples of Mrs. Pines, much finer than it is usually staged, these examples being well-coloured, and the bunches weighty. Mr. W. Smith, gr. to R. OVERT, Esq., Badgemore House, Henley-on-Thames, coming 2nd with Alnwick Seedling; and Mr. REYNOLDS 3rd with the same variety.

For three bunches of Muscat of Alexandria.—Mr. F. COLE won the premier award with perfect examples, superbly coloured, and fine in bunch and berry. Mr. GOODACKER was placed 2nd with large bunches, but scarcely so well finished; and Mr. REYNOLDS 3rd, wherein the colour was better, but the berries rather smaller than in the former case.

For three bunches of any other White.—Mr. REYNOLDS was well to the front with Chasselas Napoleon, finely finished, clear in the skin, and large in berry; Mr. TAYLOR following with Buckland Sweetwater in good condition; Mr. Lane, gr. to Miss RIDGE, Highfield, Englefield Green, 3rd with Chasselas Napoleon.

DIVISION II.

NURSERYMEN ONLY.

Collection of Fruit Trees Bearing Fruit in Pots.—Messrs. T. RIVERS & SONS, Sawbridgeworth, had no competitor in this class, their exhibit being the only one of its kind in the show. The trees were stood upon a table, and were individually beautiful pictures indeed. The following Apples we noticed:—Bijou, Cox's Pomona, Bramley's Seedling, and Bismarck; Pears, Chis. Ernest, Duchesse de Mouchy, Pitmaston Duchess, Conference, Lebrun, President D'Orsmannville, Uvedale's St. Germain, Durandau, Bergamotte d'Esperen, Doyenné du Comice, Marie Louise d'Uccle, and Durandau. Cox's Golden Drop Plum, Golden Eagle Peach, and several crabs were also included as trees in pots.

The table was capitably furnished 'twixt the pots with gathered fruits. There were splendid Grapes of Black Alicante, Muscat of Alexandria, Golden Queen (Pearson), and Gros Maroc. Peaches included Lady Palmerston and Golden Eagle. Plums: Primate (Rivers), a late red variety, Cox's Golden Drop, Decalane, Grand Duke, Jefferson, Golden Transparent, a half purple coloured sport from Golden Drop, and a medium sized yellow Plum, a seedling. Apples and Pears were well represented; Louise Bonne of Jersey was very large and well-coloured; Souvenir du Congrès and Doyenné du Comice, and other first-class Pears being shown finely. A monster fruit of Pitmaston Duchess, said to weigh 2 lb., and covered with a glass case, caused considerable attraction, as did also the large handsome fruits of Peasgood's Nonsuch Apple, and other sorts better in quality, but not so alluring in appearance. The 1st prize was well deserved, but absence of competition is regrettable.

Collection of Hardy Fruits grown partly or entirely under Glass.—The produce in this class was to illustrate Orchard-house culture; and though there was but one exhibit, this was effected fairly well. Messrs. GEO. BUNYARD & CO., Maidstone, showed, and the table laden with their produce looked capital. In the centre were fruit-trees in pots from end to end, including Vines, Pears, Apples and Figs. A plant in the centre, of Cornish Aromatic Apple, was laden with highly coloured fruits. Durandau and other Pears on trees were likewise good. The fruit on dishes, however, were the best. Such Pears as the following were granted: Doyenné du Comice, Pitmaston Duchess, Beurré Dumont, Marie Benoist, Conference, Beurré Fonqueray, Marie Louise d'Uccle, Directeur Alphonse, and Souvenir du Congrès. Of Apples, out of a large number of varieties, the following appeared specially fine: Lane's Prince Albert, Grandisier, Flander's Pearmain, Mother, Lady Sudeley, Belle de Pontolise, Gasconne's Scarlet Seedling (really wonderful in colour), Ribston Pippin, Peasgood's Nonsuch, Cox's Orange Pippin, Warner's King, Wadhurst Pippin, Baumann's Red Winter Reinette, Washington, R. Culver, Twenty Ounce, Alexander, Annie Elizabeth, &c. A few Grapes, Peaches, and Tomatoes were also included in the exhibit.

Collection of not fewer than Seventy-five or more than 100 distinct varieties of Hardy Fruits.—Messrs. GEO. BUNYARD & CO., Maidstone, were again 1st, beating two other exhibitors. It was permissible in this class to use a few foliage plants to lighten the effect of the exhibit. The most that was done in this direction was to place a Palm at the apex of a few of the more important pyramidal piles of Apples. In Messrs. BUNYARD's exhibit there was a large pile of Apples arranged in the centre, of varieties of high colour for effect, and it greatly helped to set off the exhibit. The whole of the fruits had been grown in the open air. Varieties of Apples that specially attracted attention were: Stones, Cox's Pomona, Baumann's Red Winter Reinette, The Queen, River's Codlin, Stirling Castle, Yorkshire Beauty, Washington, Lady Sudeley (capital), Newton Wonder, Bow Hill Pippin, Tibbitt's Pearmain, New Hawthornden, Vicar of Brighton, Lane's Prince Albert, Tower of Glamis, Mother, Brambling's Seedling, Fyggmore Prolific, Col. Vaughan, Twenty Ounce, Ribston Pippin, Lady Henniker, Jas. Grieve, Mère de Ménage, Cox's Orange Pippin, Lord Derby, Golden Noble, Gloria Mundi, Emperor Alexander, King of the Pippins, Of Pears the Duchesse d'Angoulême, Beurré Diel, Beurré Hardy, Conference, Doyenné Bussocch, Gansell's Bergamotte, Pitmaston Duchess, Souvenir du Congrès, Marie Louise d'Uccle, &c. The 2nd prize was taken by Mr. H. BARNWICK, Sidmouth Nurseries, Devon. A considerable part of this exhibit was arranged in baskets, and the fruit was decidedly good in quality and size. By the inclusion of a number of high coloured sorts the effect of the collection was good, though not set up so tastefully as the 1st prize exhibit.

Collection of not fewer than thirty or more than fifty distinct

varieties of Hardy Fruits.—There was only one exhibitor in this class, namely, Mr. J. COLWILL, The Nurseries, Sidmouth. All of the produce had been cultivated in the open air, and the Apples deserve the highest commendation. Most of the fruits were put up in baskets, and the best Apples in a splendid collection were Cox's Orange Pippin, Warner's King, Tyler's Kernel, Emperor Alexander, Gravenstein, Golden Noble, Dumelow's Seedling, Peasgood's Nonsuch, King of Pippins, Autumn Pearmain, Collini Pippin, Alfriston, Mère de Ménage, New Hawthornden, Beauty of Kent, Lane's Prince Albert, Worcester Pearmain, Newton Wonder, Lord Suffield. Pears were equally fine in many instances. There were also a few Peaches and other fruits.

For a Collection of not fewer than thirty or more than fifty distinct varieties of Pears in baskets or dishes grown entirely in the open air, table space of 24 feet by 8 feet.—Mr. H. BARNWICK, Sidmouth, South Devon, was 1st with fruits of medium size only, but bearing every evidence of excellent quality, the best dishes were those of Haeon's Incomparable, Durandau, Jersey Gratioli, Autumn Bergamotte, Pitmaston Duchess, Brown Beurré, Beurré Superfin, Doyenné Bussocch, and Catillac.

Collection of not fewer than thirty or more than fifty distinct varieties of Apples in baskets or dishes, grown entirely in the open air, on a table space, 24 feet by 8 feet.—This class brought forth some splendid produce from Mr. JOHN BASHAM, Nurseryman, &c., Fair Oak Nurseries, Basingstoke, near Newport, Monmouth. The finer and better known kinds were staged in square baskets, making a most effective background to those in dishes. The finer of these were Tyler's Kernel, Warner's King, Crimson Queen, Sandringham, Lane's Prince Albert, Bismarck, Beauty of Kent, Newton Wonder (extra fine), Ecklinville Seedling, Cox's Orange Pippin (very large and fine), Ribston Pippin (equally good), and Egremont Russet. This exhibit was characterised by fine finish, large size, solidity, and clearness of the skin, proving beyond any doubt that this locality is especially well suited to Apples.

DIVISION III.

FRUITS GROWN IN THE OPEN.

Gardeners and Amateurs Only.

Apples, twenty four dishes, distinct; sixteen cooking, eight dessert.—There were six collections staged. Mr. WOODWARD, of Barham Court, Maidstone, coming 1st, with superb examples of Peasgood's Nonsuch, Warner's King, Stone's Apple, Belle Dubois, Brabant Bellefleur, Tower of Glamis, Mère de Ménage, Bismarck, Ecklinville, &c. Of cooking and of dessert, fine Cox's Orange Pippin, Washington, Ribston Pippin, Gasconne's Scarlet, Alington Pippin, Calville Rouge, Baumann's Winter Reinette, and American Mother; Mr. C. A. Bayford, gr. to W. C. LEE-CAMPBELL, Esq., Gleaston Court, Herefordshire, was 2nd, having fine Warner's King, Peasgood's Nonsuch, Tyler's Kernel, Prince Albert, Stirling Castle, Pott's Seedlings, and for dessert Ribston Pippin, King of the Pippin, Cox's Orange Pippin, Mother Apple, Duchess Favourite, Baumann's Reinette; Mr. Goldsmith, gr. to Sir E. LOREN, Horsham, was 3rd, having Peasgood's Nonsuch, Prince Albert, The Queen, Cox's Pomona, Mrs. Burron, Emperor Alexander; and of desserts, Blenheim Pippin, Adam's Pearmain, Wealthy, King of the Pippin, and Ribston Pippin.

Twelve dishes distinct; eight cooking and four dessert.—There were six lots again here, the best coming from Mr. W. PRAGNELL, gr. to J. M. WINDFIELD DIBBY, Esq., Shorborn Castle, who had fine Peasgood's Nonsuch, Warner's King, Bismarck, Annie Elizabeth, Emperor Alexander, and Alfriston, with Sturmer Pippin, Cox's Orange, Ribston, and King Pippin, the latter rather poor. Mr. MILLER, gr. to T. W. STARRUP, Esq., Maidstone, was 2nd, having good Lord Derby, Warner's King, Cox's Pomona, The Queen, &c., and handsome Cox's Orange and Ribston Pippins, Worcester Pearmain, and Gasconne's Scarlet, very fine. Mr. J. HILL, gr. to C. M. W. ADAMS, Esq., Babraham Hall, Cambridge, was 3rd.

Nine dishes of Apples, six cooking and three dessert, brought two collections. Mr. BLOGROVE, gr. to Mrs. OSWALD, Reigate, was 1st, having very good samples of varieties already named; Mr. HERBERT, gr. to J. T. CHARLESWORTH, Esq., Redhill, was 2nd.

Six dishes of Cooking Apples, distinct, again brought six competitors. Mr. WOODWARD again being the fore with superb Mère de Ménage, Emperor Alexander, Peasgood's Nonsuch, Lord Derby, and Warner's King. Mr. LEWIS, gr. to T. OLIVERSON, Esq., Maidstone, was 2nd; and Mr. RICKWOOD, gr. to Lady FRAZER, Twickenham, 3rd. One collection was in this class disqualified, the exhibitor having Baumann's Red Reinette in it as a cooking Apple.

Three Dishes of Cooking Apples, distinct, had seven collections. Mr. GOLDSMITH being 1st with fine Lord Derby, Peasgood's Nonsuch, and Warner's King; Mr. J. POWELL, gr. to Col. BRYNER, M.P., Dorchester, had same varieties; Mr. A. D. COOK, Mereworth, Kent, was 3rd.

Six Dishes of Bramley's Seedling was rather a disappointing class, as the examples were rather poor. The best came from Mr. KING, gr. to J. COLMAN, Esq., Reigate; Mr. TURBOTT, gr. to J. HARRIS, Esq., Malden, Erleigh, Reigate, was 2nd; Mr. H. HOWARD, Hingham, Norfolk, coming 3rd. There were only three entries.

Six dishes of Dessert Apples, distinct, brought eight collections, colour in the class being a marked feature. Mr. WOODWARD was 1st here, having beautiful Mother Apples, Cox's Orange, Ribston Pippins, Washington, Gasconne's Scarlet, and Baumann's Red Reinette; Mr. MILLER was 2nd, having Worcester Pearmain, Blenheim Pippin, King Pippin; Mr. GOLDSMITH was 3rd.

Three dishes of Dessert Apples, distinct.—There were eleven entries in this class, Mr. BAYFORD coming 1st with King and Ribston Pippins, and Washington; Mr. A. KEMP, gr. to O. M. SCRAN DICKENS, Esq., Mersham, was 2nd, having Cox's Ribston Pippins and American Mother; Mr. R. POTTER, gr. to Mr. MARK ALLET, Bark, Sevenoaks coming 3rd.

Twelve dishes of Dessert Pears, distinct, brought six lots, the best, and a grand lot of fruit coming from Mr. G. WOODWARD, who had Doyenné-Merode, Durandau, Pitmaston Duchess, Marie Benoist, Duchesse d'Angoulême, Beurré Baltet, Emile d'Heyst, Doyenné du Comice, Beurré Superfin, and Princeps; Mr. GOLDSMITH was 2nd with Doyenné Bussocch, Marguerite Marillat, Doyenné du Comice, Souvenir du Congrès, Maie Louise, Beurré Nigor. Mr. J. POWELL was 3rd.

Nine dishes of Pears, dessert, distinct.—Here the collections were five, the best coming from Mr. W. COTTERELL, who had Pitmaston Duchess, Louise Bonne, Beurré Boac, Durandau, Gansell's Bergamotte, Beurré Hardy, and others; Mr. W. JONES, gr. to J. BROTHAM, Esq., Carshalton, was 2nd; and Mr. BACKWOOD, 3rd.

Six dishes of Dessert Pears, distinct, brought sixteen entries, the best coming from Mr. MESSINGER, gr. to C. H. BERNERS, Esq., Woolverstone, Ipswich, who had Pitmaston Duchess, Beurré Baltet, Doyenné du Comice, Beurré Hardy, Durandau, and Louise Bonne; Mr. STOBOROV was 2nd; and Mr. BASILE, gr. to the Rev. O. POWELL, Weybridge, was 3rd.

Three Dishes of Dessert Pears, distinct.—Six entries. Mr. R. EDWARDS, gr. to C. W. FIELD, Esq., Sevenoaks, had the best with Madame Treve, Doyenné du Comice, and Pitmaston Duchess; Mr. FENNELL, gr. to W. M. CAZALAT, Esq., Tunbridge, was 2nd, having Marguerite Marillat, Souvenir du Congrès, and Pitmaston Duchess; Mr. HARRIS, gr. to O. A. SMITH, Esq., East Grinstead, was 3rd.

Three dishes of cooking Pears, distinct.—Four entries. Mr. WOODWARD was 1st with fine Catillac, Triomphe de Jodoigne, and Gros Calabasse. Mr. GOLDSMITH was 2nd with Uvedale's St. Germain, Catillac, and Triomphe de Jodoigne. Mr. R. CHAMBERLAIN, gr. to F. H. MORAN, Esq., Reading, coming 3rd.

One dish of cooking Pears brought four dishes. A. O. SMITH Esq., gr. Mr. HARRIS, was 1st, having gigantic Catillac, Uvedale's St. Germain, H. Brocka, Esq., Petersham, coming 2nd.

Three dishes of Peaches, distinct, ten lots.—Mr. WOODWARD had rich-coloured fruits for the 1st prize in Princess of Wales, Sea Eagle, and Victoria; Mr. F. HARRIS, gr. to Lady H. SOMERSET, Eastnor Castle, was 2nd with Gladstone, of a rich colour; Sea Eagle, and Lord Palmerston; Mr. NANCEY gr. to Mrs. DRUCE, Mersham, was 3rd.

One dish of one variety brought three exhibits.—Mr. MITCHELL, gr. to J. W. FLEMING, Esq., Chilworth, Romsey, was 1st with handsome Sea Eagle; Mr. Lane, gr. to Miss RIDGE, Egham, being 2nd with Stirling Castle; Sea Eagle coming 3rd from Mr. GOLDSMITH.

Three dishes of Nectarines, distinct, was represented by one lot only from Mr. HARRIS, of Eastnor, who had large Pine Apple, and Albert Victor.

There were five single dishes of Nectarines.—Samples rather small; Mr. STRUGNELL, gr. to the Right Hon. W. F. LONO, M.P., Rood Ashton, was 1st with Victoria; Mr. J. HILL having Pineapple; and Mr. BRADLEY, gr. to F. W. MARVEL, Esq., Byfleet, Surrey, was 3rd with Victoria.

Four dishes of Dessert Plums, distinct, five lots. Mr. FOLKE, gr. to E. A. STRACHAN, Esq., Hemel Hempstead, was 1st with Cox's Golden Drop, Cloth of Gold, Reine Claude, and Late Transparent Gage. Mr. J. WEST, gr. to Lord BRAYBROOK, Sadron Walden, was 2nd, with Violet Reine Claude Greengage, and Cox's Golden Drop. Mr. STAGNELL was 3rd.

One dish of Dessert Plums, one variety.—The best was fine Cox's Golden Drop, from Mr. WEST; Mr. TURBOTT coming 2nd with the same variety; Monarch, from Mr. LEWIS, being oddly placed 3rd. There were eighteen dishes.

Four dishes of Cooking Plums, distinct, five lots.—Mr. GOODACKER was 1st, with fine Pond's Seedling, Goliath, Archduke, and Monarch. Mr. C. SIM was 2nd; and Mr. J. DAY, gr. to the Earl of GALLOWAY, Carlisle, was 3rd.

One dish of Cooking Plums, one variety, brought eleven dishes; Mr. OSBORN, gr. to the Rev. H. GOLDING PALMER, Reading, being 1st.

Gage Plums, one dish.—The best Reine Claude came from Mr. MESSINGER; Mr. HERRIN coming 2nd with Brady's Greengage. Mr. GOLDSMITH was the only exhibitor of four dishes of Damsons, with ordinary varieties.

DIVISION IV.

COOKING APPLES.

Alfriston, of which there were seven dishes, led the way. Mr. J. MCKENZIE, gr. to F. S. W. CORNWALLIS, Esq., Linton Park, Maidstone, was 1st with very fine examples; Mr. G. WOODWARD, gr. to R. LEIGH, Esq., Barham Court, Maidstone, 2nd; and Mr. W. LEWIS, gr. to J. OLIVERSON, Esq., East Sutton Park, Maidstone, 3rd.

Beauty of Kent was represented by nine dishes. Mr. R. CHAMBERLAIN, gr. to T. M. LOWENSON, Esq., Cressingham Park, Reading, was 1st with finely finished fruit; Mr. G. WOODWARD, 2nd; and Mr. A. BASILE gr. to the Rev. O. L. POWELL, 3rd.

Bismarck was represented by eleven dishes. Mr. J. MCKENZIE was 1st with very fine fruit indeed, large, even, bright; Mr. G. WOODWARD came 2nd, smaller, but a perfect half-dozen and Mr. C. ROSE was 3rd.

Bramley's Seedling was represented by four dishes

good, the 1st prize going to Mr. C. A. Bayford, gr. to C. LEE CAMPBELL, Esq., Gleston Court, Ross, who had clean, bright, even fruit. Mr. S. Lyon, gr. to J. H. SALMON, Esq., Holly Bank, Rowton, Chester, was 2nd with large specimens, a little uneven; Mr. J. Hill, gr. to C. R. W. ADEANE, Esq., Babraham Hall, Cambridge, was 3rd.

Cellini Pippin.—There were thirteen dishes of this variety, all very bright in appearance, the 1st prize was taken by Mr. G. Goldsmith, gr. to Sir E. G. LODGE, Bart., Leonardale, Horsham, with fine, brilliantly-finished examples; Mr. C. A. Bayford was 2nd, also with an excellent lot, and Mr. J. Powell, gr. to Col. BRYMER, M.P., 3rd, with good fruit.

Cox's Pomona brought seventeen dishes, all finely-coloured fruits; Mr. J. McKENZIE was 1st with extra bright coloured specimens; Mr. J. POWELL was 2nd, and Mr. G. Goldsmith, 3rd, both showing this favourite in excellent character.

Duchess of Oldenburgh was represented by seven dishes of uneven character; the 1st prize was taken by Mr. JAMES COULTON, Dildawn Gardens, Castle Douglas, N.B., with examples that showed the type in its best character. Mr. T. W. Herbert, gr. to J. T. CHARLESWORTH, Esq., Nutfield Court, Redhill, was 2nd with rather larger but less perfect specimens; and Mr. G. Goldsmith 3rd.

Dumelow's Seedling brought sixteen dishes, all good, a few exceptionally fine. Mr. J. McKENZIE was 1st with superb fruits, large, even, bright; Mr. W. G. PRAGNELL, gr. to J. K. O. WINGFIELD DIGBY, Esq., Sherborne Castle, Sherborne, was 2nd, with very bright but less even specimens; and Mr. C. A. Bayford 3rd.

Ecklinville Seedling.—Of this there were fifteen dishes. Mr. J. McKENZIE taking the 1st prize with large even fruits of a bright clear yellow tint; Mr. J. SPOTTISWOOD, Queen's Park, Brighton, was 2nd, also with well finished examples; and Mr. G. Woodward a good 3rd.

Of *Emperor Alexander* there were ten dishes, large, bright, highly finished fruit, taking the leading prizes. Mr. J. McKENZIE was again to the fore with superb examples; Mr. G. Woodward was 2nd with smaller, but very bright Apples; and Mr. G. Goldsmith a close 3rd.

Frogmore Prolific was represented by six dishes, varying in character, doubtless owing to difference in locality. Mr. J. McKENZIE was again 1st, with very fine fruits; Mr. C. A. Bayford, 2nd; and Mr. W. G. PRAGNELL, 3rd.

Golden Noble brought twelve dishes, some especially bright in colour. Mr. G. CHAMBERS, Moorcocks Farm, Mereworth, Maidstone, was 1st, with very bright, clean even fruits, rather more conical in shape than is usually seen. Mr. G. Woodward, was 2nd, with bright fruit, a little uneven in size; and Mr. J. McKENZIE, 3rd.

Golden Spire.—There were six dishes. The best coloured and most even being from Mr. G. Woodward; an unusually fine lot of fruit. Mr. G. Goldsmith was 2nd; and Mr. W. Lewis, gr. to T. OLIVERSON, Esq., East Sutton Park, Maidstone, 3rd.

Grenadier was represented by three dishes only, so no exhibitor went empty away. Mr. C. HERRIN, gr. to Lady L. FORTESCUE, Dropmore, Maidenhead, was 1st; large, even well-finished fruit being staged. Mr. W. Lewis was 2nd; and Mr. J. HILL, 3rd.

Hawthornden (New).—Was represented by four dishes. Mr. G. Woodward coming 1st with very fine examples. Mr. A. Brooks, Latter's Farm, Mereworth, Kent, was 2nd, also very fine; and Mr. T. W. HERBERT was 3rd.

Horned's Pearmain brought two dishes only. Mr. J. McKENZIE was 1st with very fine fruit; and Mr. J. HILL 2nd, with much smaller examples, even and clean.

Lane's Prince Albert evidenced its growing popularity by being represented in 14 dishes; here Mr. C. Ross, gr. to Capt. A. J. CARSTAIRS, Welford Park, Newbury, was 1st with remarkably fine large and bright fruit. Mr. C. A. Bayford was 2nd also with fine Apples, though lacking the colour of Mr. Ross' fruit; and Mr. G. Woodward was 3rd.

Lord Derby.—Was also represented by very fine examples. 12 dishes being staged. Mr. G. Fennell, gr. to W. M. CAZALET, Esq., Fairlawn, Tonbridge, Kent, was 1st with highly-finished specimens. Mr. R. Edwards, gr. to G. N. FIELD, Esq., Beechy Lees, Sevenoaks, was 2nd with smaller but clearer and better-coloured fruits; and Mr. C. HERRIN was 3rd. One fine dish was labelled by the judges as "not Lord Derby."

Lord Grosvenor was shown in four dishes, Mr. G. Woodward coming 1st, with large, very bright, and perfect examples; Mr. C. HERRIN was 2nd; and Mr. F. Harris, gr. to Lady H. SOMERSET, Eastnor Castle, Ledbury, 3rd.

Lord Suffield brought fifteen dishes, varying in size. Mr. J. McKENZIE was again 1st, with really superb fruits, even, and very bright; Mr. G. Woodward was 2nd, also with very fine specimens; and Mr. R. Chamberlain, gr. to F. M. LONERGAN, Esq., Cressingham Park, Reading, 3rd.

Mère de Ménage was in very fine character. Mr. McKENZIE taking the 1st prize, with very large, even, highly-coloured fruit; Mr. C. Ross was 2nd, with little smaller but equally well coloured examples; and Mr. G. Woodward 3rd. There were seven dishes.

Northern Greening brought three dishes only. Mr. C. Ross was 1st, with good-sized, well-coloured fruit; Mr. A. Brooks was 2nd; the third prize was evidently withheld.

Newton Wonder was shown in two classes, in the first it was necessary the exhibitors lived in Cardigan, Radnor, Shropshire, Stafford, Warwick, Northampton, Bedford, Cambridge, Essex, or counties further north. Two dishes were staged: Mr. J. HILL, Babraham Hall, was 1st with very fine fruit; and Mr. H. H. HURNARD, Gurney Manor, Higham, Norfolk, 2nd with larger fruit, a few somewhat spotted. In the following class for the same variety from growers living south of the

foregoing counties: Mr. R. EDWARDS, Beechy Lees, was 1st with an excellent dish of even fruits; Mr. G. Goldsmith, was 2nd, with fruit showing more colour, even, and clean; and Mr. J. Harris, gr. to P. CROWLEY, Esq., Waddon House, Croydon, 3rd; there were four dishes.

Peargood's Nonsuch was represented by some stupendous specimens: Mr. J. McKENZIE taking the 1st prize with very large even, bright fruits; Mr. W. A. McKENZIE, gr. to the LORD BISHOP of Bath and Wells, the Palace, Wells, was 2nd, also with very fine apples; and Mr. F. G. POWELL, the Horticultural College, Swanley, 3rd; nine dishes were staged.

Potts' Seedling was represented by eleven dishes. Mr. T. Turton, gr. to J. HARGREAVES, Esq., Maiden Erlegh, Reading, was 1st, with very good examples; Mr. G. Woodward, was 2nd, also with very fine fruit; and Mr. J. Hudson, gr. to L. de ROTHSCHILD, Esq., Gunnersbury House, Acton, 3rd.

Royal Jubilee brought one dish only from Mr. C. Ross, but the fruits were a very good representation of the variety.

Saundersham was well represented by nine dishes; Mr. J. McKENZIE adding another to his successes, taking the 1st prize with a superb dish. Mr. G. Wythes, gr. to Earl PERCY, Syon House, Brentford, was 2nd, also with an excellent dish; and Mr. C. Ross, 3rd.

Spencer's Favourite, which is very like Golden Noble in appearance, was seen in four dishes, Mr. G. Woodward coming 1st with perfect fruit, yellow as a guinea; Mr. W. Jones, gr. to G. R. BROUGHTON, Esq., Wellington Bridge, Carshalton, was 2nd, with rather larger but not such well-finished fruit; and Mr. W. B. MILLET, gr. to T. W. STARTUP, Esq., West Fareleigh, Maidstone, 3rd.

Stirling Castle brought ten dishes varying in size; Mr. J. McKENZIE was 1st with a really perfect dish; Mr. W. Strugwell, gr. to the Rt. Hon. W. H. LOXO, M.P., Rood Ashton, Trowbridge, was 2nd; and Mr. W. King, gr. to J. COLMAN, Esq., Gatton Park, Reigate, 3rd.

Stone's or Loddington Seedling brought four dishes only, and here again Mr. J. McKENZIE was 1st with finely-matured fruit; no 2nd or 3rd prize appears to have been awarded.

The Queen brought bright-coloured fruits, and here again Mr. J. McKENZIE took 1st prize with a dish of large, even and bright Apples. Mr. G. Woodward was a good and close 2nd; and Mr. C. HERRIN, 3rd, his fruits being brilliantly-coloured.

Tower of Glamis was represented by eight dishes; Mr. J. McKENZIE was 1st with examples which left little to be desired, so perfect were they; Mr. A. Brooks, Mereworth, was 2nd, and Mr. C. A. Bayford, 3rd.

Tyler's Kernel was seen in three dishes, Mr. J. McKENZIE showing again very fine indeed, conical in shape, and perfectly finished; Mr. J. HILL, Babraham Hall, was 2nd; and Mr. A. Basile, gr. to the Rev. R. A. POWELS, Woburn Park, Weybridge, 3rd.

Warner's King was numerously represented, there being twenty-four dishes, some very fine. Here again Mr. J. McKENZIE came in 1st with a splendid dish—large, bright, even. Mr. G. CHAMBERS, Mereworth, was 2nd with large fruits not so freely coloured; and Mr. G. Woodward was 3rd.

In what might be termed a consolation class for any other variety there were seventeen dishes. Mr. J. McKENZIE coming 1st with a superb dish of Dutch Codlin finely coloured. Mr. W. Camm, gr. to the Duchess of CLEVELAND, The Abbey, Battle, Sussex, was 2nd with an admirable dish of Lady Henniker; and Mr. G. FENNELL, Tonbridge, 3rd with Castle Major. Manx's Codlin, Gloria Mundi, Councillor, Anne Elizabeth, Hollandbury, Belle Dubois, and others were staged.

DESSERT APPLES.

Adam's Pearmain was represented by seven dishes. Mr. W. Camm, gr. to the Duchess of CLEVELAND, The Abbey, Battle, was 1st, with regular, handsome specimens. Mr. G. Goldsmith, gr. Sir E. G. LODGE, Leonardale, Horsham, was 2nd, also with very good fruits; and Mr. G. Woodward, 3rd.

Of *Allen's Ever-ating*, three dishes only were staged: Mr. J. Powell, gr. to Col. F. YMER, M.P., was 1st, with well-coloured fruit. Mr. W. H. Godden, gr. to The Hon. F. W. BUXTON, Cashibury, Sawbridgeworth, was 2nd, with good fruit, lacking colour; and Mr. J. SPOTTISWOOD, Queen's Park, Brighton, was 3rd.

Baumann's Red Winter Reinette produced nine dishes, all finely coloured; Mr. J. McKENZIE, gr. to F. S. W. CORNWALLIS, Esq., Linton Park, Maidstone, was 1st with very fine specimens; Mr. C. Ross, gr. to Capt. A. J. CARSTAIRS, Welford Park, Newbury, was 2nd, having very fine fruit also; and Mr. H. C. PRINSEP, gr. to Viscountess PORTMAN, Buxted Park, Uckfield, was 3rd.

Cl Blenheim Orange there were seventeen dishes, Mr. W. H. Godden taking the 1st prize with large and bright fruits; Mr. G. CHAMBERS, Moorcocks Farm, Mereworth, Kent, was 2nd, with smaller but very handsome, bright fruit; and Mr. W. King, gr. to J. COLMAN, Esq., Gatton Park, Reigate, was 3rd.

Brownlee's Russet was represented by seven dishes, but one of them was labelled by the judges, Old Royal Russett. Mr. G. Woodward was 1st, having the type well represented; Mr. H. C. PRINSEP was 2nd; and Mr. A. H. RICKWOOD, gr. to the Dowager Lady FRAKE, Fulwell Park, Twickenham, 3rd.

Of *Claygate Pearmain* there were five dishes. Mr. G. Woodward was 1st, having this variety very fine; Mr. H. C. PRINSEP was a good 2nd; and Mr. W. H. Godden 3rd.

Court Pendu Plat was represented by fifteen dishes, some richly coloured. Mr. J. C. Tallack, gr. to E. DRESDEN, Esq., Livermore Park, Bury St Edmunds, was 1st, with very fine

fruits; Mr. C. Ross 2nd; and Mr. R. Chamberlain, gr. LONERGAN, Esq., Cressingham Park, Reading, 3rd. *Cox's Orange Pippin* was in force; twenty dishes being some finely finished. Mr. W. Messenger, gr. to BERNERS, Esq., Woolverstone Park, Ipswich, was large, even bright fruit, not so brilliantly coloured. Mr. W. KING, came 2nd with highly-finished fruit; and Mr. G. Woodward, was 3rd.

Egremont Russet brought two dishes only, Mr. SMITH, Leonardale, was 1st with very good exam. W. B. MILLER, gr. to T. W. STARTUP, Esq., West Maldstone, 2nd.

Fearn's Pippin was finely shown, fifteen dishes being, Mr. J. C. TALLACK was 1st with brilliant fruit, 1 very bright fruit; Mr. J. McKENZIE coming 2nd, at Jones, gr. to G. R. BROUGHAM, Esq., Wallington, Carshalton, 3rd, and like the preceding, finely finished.

Gascogne's Scarlet was represented by seven dishes showing off this brilliant Apple to the best advantage. J. McKENZIE was 1st, with grand samples. Mr. J. gr. to L. de ROTHSCHILD, Esq., Gunnersbury House, 2nd, and Mr. G. Woodward 3rd, both having very fine fruit.

King of the Pippins came to the fore in nineteen dishes. Mr. J. C. TALLACK was 1st, with fruits requiring to make them perfect examples. Mr. J. POWELL was 2nd, and Mr. C. A. Bayford, gr. to C. LEE CAMPBELL, Esq., Court, Ross, 3rd.

King of Tomkin's County brought fine dishes, vary what in appearance. Mr. T. Turton, gr. to J. H. HALL, Esq., Maiden Erlegh, Reading, was 1st with large, richly-coloured fruit; Mr. J. C. TALLACK was 2nd good dish indeed, but lacking colour; and Mr. J. H. C. W. P. ADEANE, Esq., Babraham Hall, Cambridge. Of *Mahbot's Pearmain* there were but two dishes. Mr. J. McKENZIE was 1st with excellent fruit; and PRINSEP, 2nd.

Mannington's Pearmain brought eight dishes. Woodward was 1st with very good specimens. McKENZIE was 2nd, and Mr. T. TURTON, 3rd.

Of *Margil* there were ten dishes, the 1st prize going to Woodward, with very bright specimens; Mr. J. J. was 2nd; and Mr. C. A. Bayford, 3rd.

American Mother was represented by six dishes. Bayford was 1st with conical, high-coloured fruit. McKENZIE was very close up as 2nd; and Mr. SMITH, 3rd.

Ribston Pippin brought twenty-two dishes; so fruit being wonderfully fine. Mr. G. Woodward was perfect examples; Mr. J. McKENZIE with fruit, only inferior, was 2nd; and Mr. C. A. Bayford, 3rd.

Scarlet Nonpareil produced seven dishes, but one was marked Ross Nonpareil. Mr. J. HUDSON came perfect fruits, very even and fine; Mr. C. Ross, 2nd good fruits, was 2nd; and Mr. J. HILL, 3rd.

Of *Starmer Pippin* there were nine dishes, Mr. PRAGNELL, gr. to J. K. D. WINGFIELD DIGBY, Esq., T. Sherborne, was 1st with remarkably good fruit. CHAMBERLAIN came 2nd, and Mr. C. Ross 3rd.

Williams' Favourite was represented by one dish, bright fruits, from Mr. J. Powell, gr. to Colonel M.P., Haslington House, Dorchester.

Worcester Pearmain was in force, nineteen dishes being staged. Mr. W. KING, Gatton, the 1st prize with grandly coloured fruit; Mr. G. V. was 2nd, and Mr. W. MESSENGER 3rd.

Any other Variety brought twenty-four dishes. McKENZIE was 1st with a dish of St. Edmund's very handsome golden fruit russet; Mr. G. GOLDSMITH was 2nd with finely coloured Gravenstein; and Mr. G. was 3rd with fine Washingtons. Wealthy, Beauty Allington Pippin, Parrotquet, Kentish Pippin, varieties were shown.

DESSERT PEARS.

Bergamotte Espéren.—There were eight dishes of Mr. J. POWELL, Islington House, was 1st, with an dish; Mr. C. Ross was 2nd, and Mr. G. Woodward 3rd. *Beurré Bosc* was represented also by eight dishes. Goldsmith was 1st, with very fine fruit; at Cotterell, gr. to Sir W. N. M. GEARY, Bart., Oxon, Tonbridge, 2nd; Mr. W. B. OSBORN, gr. to the PALMER, Holme Park, Reading, was 3rd.

Beurré d'Anjou brought one dish only, a very from Mr. G. Woodward.

Beurré Diel was in force, fourteen dishes being. Mr. G. Woodward was 1st, with some large and specimens; Mr. G. WYTHES was 2nd, also with a good fruit; and Mr. G. Goldsmith 3rd.

Beurré Dumont brought two dishes. Mr. G. V. again was 1st, with even, handsome fruits; and Mr. W. was 2nd, with riper Pears, but not so good in appearance. *Beurré Hardy* produced eight dishes. Mr. G. V. was again to the fore with splendid examples; PRINSEP was a remarkably good 2nd; and Mr. V. GER, Wolverstone Park, was 3rd.

Beurré Superfin was represented by eleven dishes. Woodward again 1st, with a very fine even dish. Goldsmith was 2nd; and Mr. John Webb, gr. WICK, Esq., Manor House, Horsham, 3rd.

William's Bon Chretien brought two dishes, one Mr. James Day, gr. to the Earl of GALLOWAY House, Garliston, N.B., was 1st, with very good fruit. *Comte de Lamy* brought three dishes only: Mr. was 1st. Mr. T. W. HERBERT, Nutfield Court, 2nd. G. Goldsmith, 3rd.

Conference secured five dishes. Mr. G. Woodward with an excellent representation of the variety.

Slogrove, gr. to Mrs. CRAWFORD, Gatton Cottage, Reigate 2nd, also with good fruit; and Mr. J. POWELL, 3rd.

There were six dishes of *Conseiller de la Cour*; Mr. J. O. TALLACK coming in 1st with very fine examples; Mr. A. BABLE, with good fruit was 2nd; and Mr. C. A. BAYFORD, 3rd.

Doyenné du Comice was represented by ten dishes, some very good; Mr. J. POWELL came in 1st with a superb dish; Mr. B. CALVERT, gr. to Col. ARCHER HOUBION, Bishops Stortford, was a good 2nd; and Mr. G. WOODWARD, 3rd.

Duchesse de Bordeaux.—There were but two dishes. Mr. G. GOLDSMITH was 1st; and Mr. G. WOODWARD, 2nd.

Durondeau was represented by eight very fine dishes. Mr. G. WOODWARD was 1st, with superb examples; Mr. W. G. FRAGNELL was 2nd; and Mr. W. COTTERELL, 3rd.

Entée Beurré brought seven dishes, Mr. B. CALVERT taking the 1st prize with handsome, even-sized fruit. Mr. G. WOODWARD was 2nd; and Mr. W. COTTERELL, 3rd.

Three dishes of *Emile d'Hayot* were staged; the best came from Mr. G. WOODWARD; Mr. W. STRONGELL, Rood Ashton, was 2nd; and Mr. G. GOLDSMITH, 3rd.

Fondante d'Automne was represented by four dishes. Mr. A. BABLE was 1st with a capital fruit; Mr. T. TURTON, 2nd; and Mr. G. GOLDSMITH, 3rd.

Fondante de Thérèse.—There were three dishes of this Pear. Mr. WOOD was again 1st with a perfect dish, Mr. W. MESSENGER was 2nd; and Mr. J. NICHOLSON, gr. to J. W. MELLIS, Esq., Sewardstone Lodge, Chingford, 3rd.

Glow Morpheus.—This was shown in fine character, Mr. J. POWELL taking the 1st prize; Mr. J. WOODWARD was 2nd with rather larger fruit, not so well finished; and Mr. B. CALVERT 3rd.

Out of thirteen dishes of *Josephine de Malines*, Mr. J. POWELL was 1st with a very even, handsome sample; Mr. T. W. HERBERT was 2nd, and Mr. B. CALVERT 3rd.

Louise Bonne of Jersey was represented by ten dishes, some of them brilliantly coloured; Mr. J. COLES, gr. to H. F. WALKER, Esq., Highley, Balcombe, Sussex, was 1st with superb examples; Mr. W. MESSENGER was 2nd; and Mr. G. GOLDSMITH 3rd.

Maria Bonnet brought three dishes. Mr. G. WOODWARD was 1st with very fine examples; Mr. G. MESSENGER was a very good 2nd; and Mr. G. WYTHES 3rd.

Maria Louise was in good character, ten dishes being staged. Mr. B. OSBORN took the 1st prize with very fine fruit; Mr. G. WOODWARD, only just beaten, was 2nd; and Mr. G. GOLDSMITH 3rd.

Maria Louise d'Ucle was represented by seven dishes. Mr. W. COTTERELL taking the 1st prize with large and highly-finished fruit; Mr. G. WOODWARD was 2nd; and Mr. G. GOLDSMITH, who had the largest but the greenest fruit 3rd.

Of *Marguerite Marillat*, two dishes only were staged, both very fine, and perfectly ripe. Mr. G. GOLDSMITH was 1st, and Mr. EDWARDS, Beechey Lees, 2nd.

There were five dishes of *Nouvelle Fulvie*. Mr. G. WOODWARD was 1st, with very fine fruit; Mr. G. GOLDSMITH 2nd; and Mr. G. WYTHES 3rd.

Olivier de Serres.—The best dish of this variety came from Mr. G. GOLDSMITH; Mr. G. WOODWARD was 2nd, and Mr. G. NICHOLSON 3rd. Four dishes were staged.

Palmatin Duchess was represented by twelve dishes of superb fruits. Mr. W. COTTERELL was 1st, with grand examples; Mr. G. WOODWARD 2nd; and Mr. C. HARRIS, gr. to O. A. SMITH, Esq., Hammerwood, East Grinstead, 3rd.

Sekle was represented by three dishes only; Mr. C. ROSS was 1st with a very fine sample, Mr. T. TURTON 2nd, Mr. F. HARRIS, Eastnor Castle, 3rd.

Two dishes only of *Succaire du Comice* were staged. Mr. G. GOLDSMITH was 1st with some very fine fruit, and Mr. G. NICHOLSON, Fairlawn, Tonbridge, 2nd.

Thompson's Pear was represented by five dishes. The best came from Mr. J. POWELL; Mr. W. COTTERELL was 2nd, and Mr. SLOGROVE 3rd. Mr. POWELL'S Pears were particularly fine.

Winter Nellis brought twelve dishes. Here again Mr. WOODWARD took the 1st prize, having superb fruit. Mr. GOLDSMITH was a good 2nd, and Mr. F. HARRIS 3rd.

Any other variety was represented by nineteen dishes, the 1st prize going to Mr. G. WOODWARD, for magnificent Gansel's Pergament; Mr. J. SPOTTISWOOD, Brighton, was 2nd, with *Doyenné Boursnois*; and Mr. G. GOLDSMITH 3rd, with *Rivers' Princess*. Madame Treyve, Brockworth Park, Duchess d'Angoulême, and Beurre Bachelier, with others, were shown in good character.

DIVISION V.

THE VEITCH PRIZES FOR FLAVOUR.

In the competition for flavour in Apples as many as forty-four dishes were staged. Mr. H. C. PRINCEP, was 1st with Ribston Pippin, finely-coloured fruits, firm yet ripe; Mr. C. PERRIN, gr. to Lady FORTESCUE, Dropmore, Maidenhead, being 2nd with Cox's Orange Pippin, which were scarcely ripe.

Thirty-two dishes of Pears were staged. Mr. B. OSBORN, gr. to Rev. H. GOLDING PALMER, Holme Park, Reading, was 1st with good examples of Louise Bonne of Jersey, in first rate condition; Mr. COTTERELL, gr. to Sir WM. GEARY, Bart., Tonbridge, with *Fondante d'Automne*, the examples being of medium size.

The Luncheon.

THE customary luncheon took place on Thursday in the Garden Hall. Sir Trevor Lawrence, President of the Royal Horticultural Society, presided, and among those present were Messrs. T. B. Haywood, P. Crowley, J. T. Bonnett-Poe and R. McLehlan (members of Council); Mr. J. T. Rait,

chairman of the Crystal Palace Company, Mr. W. Gardiner, Secretary; and Mr. H. Gilman, Manager; the Rev. W. Wilks, Mr. Arthur W. Sutton (Reading), Mr. G. Bunyard, Mr. Owen Thomas, and a number of representative gardeners.

The toasts of the Queen and the other members of the Royal Family having been enthusiastically honoured, the Chairman proposed "Prosperity to the Crystal Palace Company." He said the Royal Horticultural Society were deeply indebted to the Crystal Palace Company for the help they gave the fruit industry by supporting such shows as the present. One thing they ought not to forget, and that was that, while great progress had been made in every art and science during the Queen's reign, the fruit-growing art had not lagged behind. He wished the Crystal Palace Company every success. Mr. J. T. RAIT, Chairman of the Crystal Palace Company, responded. He said he and the directors were only too pleased to see the Royal Horticultural Society again holding their show at the Palace and hoped they would do so for many years to come. He expressed the hope that alterations that had been made in the arrangement of the central transept met with their approval.

With regard to the many rumours as to the alleged intended sale of the Crystal Palace, he asked them to look upon them as merely rumours, and nothing else. The company suffered considerably from the Jubilee, but it was satisfactory to know that their flag still floated on Sydenham Hill. It was the intention of the directors to continue to make the Palace worthy of the glorious traditions of the past. There certainly had been an attempt to induce the London County Council to buy the Palace, but beyond that, the rumours were worth nothing. He always held that the Palace should be a national institution, but as long as it remained under its present conditions, the company looked for the generous support and sympathy of the public.

The Chairman next proposed "The Judges," and referred to them as the finest body of experts in matters of fruit growing in the kingdom. As to the Crystal Palace Company, he agreed with Mr. RAIT that it should be a National Institution.

Mr. OWEN THOMAS, The Queen's Gardener, responded.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

SEPTEMBER 23.—Present: G. Shorland Ball, Esq., Ashford, in the Chair; also Messrs. S. Gratrix, Westhams, Greenwood, Johnson, Captain Schofield, Jas. Anderson, W. A. Gent, Wm. Bolton, and E. J. Sidebotham.

From H. H. BOLTON, Esq., Heighside, Newchurch (gr., Mr. Eastwood), came *Calanthe* × *Eclipse* = *Sanderiana* × *veratrifolia*, an interesting but ineffective cross; also a good *Cattleya speciosissima*, a bright-lipped *Cattleya aurea* (Award of Merit).

G. SHORLAND-BALL, Esq., Ashford, Wilmsham (gr., Mr. A. Hay), showed the beautifully-coloured *Vanda Kimballiana* (Award of Merit); also a very pale form of *Odontoglossum Bictoniense* (Award of Merit).

W. H. ALMOND, Esq., Almscar, near Blackburn, had a fine fresh-looking plant of a good form of *Miltosia Morelliana*, which was voted an Award of Merit.

WM. THOMPSON, Esq., Walton Grange (Mr. Stevens, gr.), sent a fine cut spike of *Odontoglossum acceptrum* which seems to be in some way allied to *O. luteo-purpureum*.

SAMUEL GRATRIX, Esq., West Point, Whalley Range (Mr. D. McLeod, gr.), sent *Cypripedium* × *Lowergremmii* = *Spiracanthum* × *logrande*, which received an Award of Merit, but the committee doubted the correctness of the alleged parentage, and the plant, when flowering next time, should be again brought before it. The same exhibitor had *Cypripedium* × *Callo Rothschildianum*, which was thought to resemble Lord Derby, a variety already certificated. It differs, however, in the arrangement of the petals. This exhibitor had also *O. × memoria Mossii*. An Award of Merit.

THOMAS STATTEN, Esq., Stand Hall, Manchester (Mr. R. Johnson, gr.), had a very good cross of *Cypripedium Stonei* × *Rothschildianum*, bearing the narrowish segments of both parents, as well as a good ground-colour and pretty spotting. It was not named.

JOHN LEMANN, Esq., West Bank House, Winton-Mersey (Mr. Edge, gr.), had the beautiful *Phaius Ashworthii* × *P. Maurel* × *P. maculata*, a fine yellow flower with a tasseled lip—a very striking novelty. It received an Award of Merit.

WM. BOLTON, Esq., Wilderspool, had a choice group nicely flowered, consisting of a plant of *Cattleya superba* with six flowers on a spike, and a pretty-coloured variety of *C. Eldorado splendens*; also a finely-formed and coloured *C. gigas Sanderiana* (Award of Merit); *Cattleya Schofieldiana*, a large flower, nicely spotted, received an Award of Merit while another one with a crowd of flowers upon it received a Cultural Certificate.

The Ven. Archdeacon RAWSTORNE, Balderstone Grange, Blackburn showed a splendidly-grown plant and variety, with over a dozen flowers, of the rather scarce *Miltosia Morelliana atrovirens*. The size, form, and finish of this remarkable variety impressed the committee, and they awarded it the only First-class Certificate of the day.

JOHN LEMANN, Esq. (Mr. Edge, gr.), had a group of freely-flowered Orchids set amongst Maidenhair Ferns, which relieved the monotony of the single exhibits at the time of the year when there is no wealth of Orchid-flowers, of *Odontoglossum crispum*, grande, and other *Odontoglossa*, *Cattleyas*, and a good assortment of the inmates of the cool and warm houses. He was awarded the Silver Medal of the

Society. A pleasing design in Orchid-flowers with a portrait of Darwin on the obverse was shown by this exhibitor. There has been no Gold Medal, which is a facsimile of the Silver one, made up to the present. It is a matter of congratulation to take the highest award of this Society. J. A.

BOTANIC GARDEN, OLD CALABAR.

THE following is an extract from a letter received from Mr. John Henry Holland, whose appointment as Assistant-Curator of the Botanic Station in the Niger Coast Protectorate was announced in the *Kew Bulletin*, 1896, p. 147.

"The gardens are well situated, on rising ground, covering altogether about 45 acres. This includes a large area planted with Coffee, a small proportion with Cocoa, whilst experimental grounds and nursery occupy the remaining part. There is, I can assure you, plenty to do.

"The quarters are good, situated conveniently in the gardens, on a hill about 160 feet high. We have not a very extensive view of the surrounding country, being partly enclosed with dense bush. We can, however, see Duke Town at the foot of the hill, and catch a glimpse of the river, with an occasional sight of a steamer passing by to the anchorage."

THE BULB GARDEN.

IXIAS

are admirable plants for pot-culture for greenhouse-decoration in the spring, and the bulbs may be potted at this season, putting eight or nine bulbs in a 6-inch pot, using sandy loam and leaf-soil, and placing them in a cold pit, where they may remain till in flower. The graceful flower-sprays of the different varieties have a nice effect when placed amongst other plants, or in jardinières and vases.

WATSONIA ROSEA

has long and handsome flower-spikes, and the plant is suitable for conservatory-decoration in the early summer months, if treated somewhat similar to the early varieties of *Gladiolus*. J. Baxter.

Obituary.

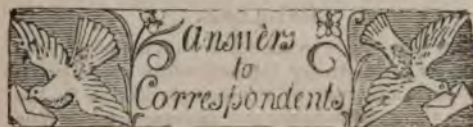

F. E. MCALLISTER OF NEW YORK.—We read in the *Florist's Exchange* of the death, on Tuesday, September 14, of Mr. F. E. McAllister, for twenty-five years carrying on an extensive seed and importing business in New York, his specialties being flower, field, and garden seeds, bulbs, implements, and sundries. The deceased was 53 years of age.

MR. J. H. CLEMENTS.—It is with regret that I have to record the death of Mr. J. H. Clements, at Brambling House Gardens, Chesterfield, on Sept. 22, at the age of fifty-five. A Kentish man by birth he went through the usual course of instruction in good establishments, going from a place in Worcestershire, to Mr. M. Dunn, at Dalkeith Palace Gardens, and thence to take charge of the gardens at Whittington Hall, Chesterfield, where he made numerous improvements while in the employ of the late W. Fowler, Esq. At the death of Mr. Fowler, fourteen years ago, he went to take charge of the gardens then being formed at the new residence of T. P. Wood, Esq., Brambling House, and with an employer liberal and enthusiastic in horticultural matters, Mr. Clements found a suitable sphere for his abilities in the forming and planting of artistic rock-work in a large house for Palms, Ferns, &c., besides houses for other plants and fruit, and a large show-house for Chrysanthemums. A cold, taken a fortnight ago, followed by pneumonia, was the cause of his untimely end. Mr. Clements was well known and respected by a wide circle of friends. W. Parks, Whittington Hall Gardens, Chesterfield.

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

THREE CROPS OF FLOWERS FROM CATHERINE MERMET ROSE IN ONE YEAR IN DENMARK.—Can any of our readers inform A. J. S. if such an occurrence is usual.

A GOOD MARKET TOMATO: H. E. T. Try Young's Eclipse or Frogmore Selected.

BASKET WILLOWS: J. A. For strong work, *Salix conformis*, the shoots grow from 7 to 10 feet long, will do well on wet soil; a good coppice wood, the wood being pliable and tough. *S. purpurea*, a fine quality of Willow, rods straight and long, a good cropper on rich land, shoots tough and pliable, and leaves bitter, making it distasteful to stock—excellent for fine basket work. *S. Hoppeana*, a French Willow, shoots 5 to 7 feet long, may be used peeled or brown. *S. Helix* (Rose Willow), used for the best small work. Grows best on warp land; on strong land it is short and scrubby.

BOOKS: E. C. C. W. You should obtain Mr. Williams' *Orchid Manual*, published by B. S. Williams & Son, Paradise and Victoria Nurseries, Upper Holloway, N.

CARNATIONS AND PINKS: X. The first have originated from *Dianthus caryophyllus*, and the second from *D. plumarius*. Numerous crosses have been raised between most diverse species, and between crosses, consequently the characteristics in regard to form and colour of the flowers are not traceable. Some hybridists have regarded the garden Pink as having descended from *D. caryophyllus*, and not from *D. plumarius*. Pinks are distinguished from Carnations by their dwarfer habit, narrower leaves, more decidedly perennial character, pungent balsamic fragrance, and their capability of being propagated by division of the root.

CHALLENGE BOILER: E. R. B. We are unable to give the name of the maker. We do not find the name you mention as a boiler maker in London, or in the country with an office in town. You should advertise in our columns.

CORDYLINES (DRACENAS): T. G. H. Such root-stocks as those sent could not be expected to bear healthy free growing heads. Strike fresh tops, and when they are free of the old cankered base, they will thrive satisfactorily.

FIGS: W. H. H. To prevent the fruits falling prematurely from out-of-door Fig trees, direct your efforts to obtain a thorough ripening of the wood each autumn. If the tree is growing too strongly you must root prune. Never stop a shoot unless it is uncommonly strong. Keep the tree thinly upon the wall by removing each season as many shoots as may be necessary. When root pruning, you had better examine to see if any of the roots are too far from the surface of the soil. They should be kept very near to the surface, and covered during winter and spring at least with a mulch of short manure. Some growers pinch the shoots in summer to effect ripening; you might try this method upon another tree, and note the result.

FUNGUS ON BLACK CURRANT LEAVES: C. E. T. The leaves are affected by the *Uredo* of *Cronartium ribicola*, the ascidium stage of which affects the bark of *Pinus strobus*. The disease, as it appears on the leaf of the Currant, is figured in the *Gardeners' Chronicle*, vol. xii., 1892, p. 135, and described at pp. 44 and 133 of the same volume. Every leaf, and all the prunings, should be collected and burned, and the ground under the bushes skimmed and buried deeply. Afterwards dress the trees repeatedly with the Bordeaux Mixture. It is apt to infest the other members of the *Ribes* family.

FUNGUS ON GRAPES: C. S. Certain atmospheric conditions favour the growth of moulds, and you can only take such precautions against them as the use of flowers-of-sulphur in combination with whitewash on the hot-water apparatus, keeping

sulphur in saucers of water, and using the Bordeaux Mixture in a mild form on the foliage twice or thrice during the summer, also damping the floors and walls with the same. Avoid coolness and dampness in the vineries at all times.

GRUBS: W. Lewis. The common Leather-jacket, the larvæ of the Daddy-longlegs—*Tipula oleracea*. Injurious to the roots of plants when present in great numbers in the soil. Repeated digging of the soil, and exposing it to the birds and the weather, will rid the land of them.

LILIAM CANDIDUM: S. S. D. It is quite natural for this species to make a tuft of leaves in the autumn. Do not disturb them, they gain in strength if let alone.

MUSHROOM: J. C. & Co. It is the Horse-Mushroom, *Agaricus arvensis*, and very good eating. Flavour rather stronger than that of *A. campestris*. M. C. C.

NAMES OF FRUITS.

* * Applications to name fruits are so numerous at this season, as seriously to hamper us in the exercise of our editorial duties. They entail an expenditure of time, labour, and money, of which our readers can have little idea. We are most desirous to oblige our correspondents as far as we can, but we must request that they will observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones, just approaching ripeness, and they should be properly numbered, and carefully packed. We do not undertake to send answers through the post, or to return fruit. Delay in any case is unavoidable.

C. A. B. 1, Winter Pearmain; 2, Gravenstein; 3, Roundway's Magnum Bonum; 4, Baumann's Red Winter Reinette; 5, Lemon Pippin.—Thomas Kimble. Worcester Pearmain.—H. T. 1, Beurré Diel; 2, Comte de Lamy; 3, Duchesse d'Angoulême; 4, Beurré Diel; 5, Gravenstein.—T. E. 1, Doyenné du Comice; 2, Louise Bonne of Jersey; 4, Napoéon. Apples: 1, Fern's Pippin; 2, Court of Wick; 3, Cox's Pomona; 4, Not recognised.—W. 1, Beurré Clairgeau; 2, Doyenné Boussoch; 3, Catillac; 4, Not recognised.—Jane Eyre. Small variety resembles Sussex Duck's Bill; large, Yorkshire Beauty.—C. Best. 1, Beurré Sterckmann; 4, Easter Beurré; 5, Catillac; 9, Autumn Bergamot; 3, Beurré d'Amanlis; 8, Thompson's; 7, Beurré Diel.—Roberts. 1, Duck's Bill of Sussex; 2, Not known; 3, Bleuheim Orange; 4, Cellini Pippin. The Pear was not in perfect condition.—C. Roskill. 1, Windsor; 2, Beurré d'Amanlis; 3, Hawthornden; 4, Not known; 5, Ribston Pippin; 6, Court of Wick.—T. B., Esher. 1, Cox's Pomona; 2, Lemon Pippin; 3, Not recognised.—Subscriber. 1, Beurré Hardy; 2, Beurré Bachelier; 4, Beurré Bosc; 5, Lord Grosvenor.—St. Andries. 1, 3, Old Pearmain; 2, Lane's Prince Albert; 5, Not known; 4, Edmund Jupp; 6, Hawthornden.—James Hughes. 1, 3, Not recognised; 2, Bass Pool; 4, Emperor Alexander; 6, Ecklinville; 5, Cellini.—J. H., varieties in sealed packages. 1, 3, Holland bury; 2, Gloria Mundi; 4, Allriston.—Robert King, per M. C. K. Your Pear is correctly named, Beurré Bachelier.—X. Y. Z. 1, Golden Pippin; 2, Frogmore Prolific; 3, Lord Derby; 4, Nonsuch; 6, Gloria Mundi.—C. J. Wilson. 1, Claygate Pearmain; 3, Knight's Monarch; 4, Passe Colmar; 6, Louise Bonne of Jersey; 2, Flemish Beauty and Dandelion's Seedling; 7, Col. Vaughan.—G. N. 1, Emperor Alexander; 2, Gloria Mundi; 3, Not recognised; 4, Ecklinville; 5, Duchesse; 6, Pear Beurré Hardy. (Thanks for P.O. for Gardeners' Orphan Fund).—W. P. R. The Pear is the Summer Franc Real, an abundant cropping, poor flavoured variety that may be eaten off the tree, or soon after gathering it.—W. J. B. Your specimens we are not certain of. Names shall be given next week.—Frank Ballingel. Pear pretty enough, but worthless. Flesh dry like a piece of wood.—A. M. Beauty of Kent. M. J. K. Resembling the Windsor, but bruised a good deal.—J. Russell. Red or crimson, Caraway Russet, Damson Crittenden.—J. A. Edgar. 1, Golden Noble; 4, Mère de Ménage; 9, Mère de Ménage; 6, Lord Derby; Ribston Pippin; 5, Hanwell's Souring.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—M. Outhbertson. 1, *Geranium sylvaticum*; 2, *G. phœnum*; 3, *Hypericum tetrapterum*; 4, *Astilbe chinensis*.—J. R. H. *Oncidium microchilum*, a species which bears a strong resemblance to *O. splendens* in its habit of growth.—A. T. C. 1, 2, 5, 6, 7, garden-raised variations of *Adiantum cuneatum*; 3, *Adiantum decorum*; 4, *Adiantum cuneatum*; 8, *Pteris tremula*; 9, *Pteris serrulata*; 10, *Pteris argyrea*.—F. C. 1, *Croton interruptus*; 2, *Croton Johannis*; 3, *Croton trilobus*; 4, *Croton elegans*; 5, Probably

small leaf of *C. Weissmanni*; 6, *Croton variegatus*; 7, *Tecoma australis*.—J. G. The Orchid is *Catasetum Trulla*; the other *Passiflora edulis*.—East Fairleigh. *Stanhopea Wardi aurea*, and *Odontoglossum biconense*.—X. Y. Z. 1, *Rhus typhina*; 2, *Cereus serpentinus*; 3, *Phyllocactus* sp., no flower; 7, *Achillea ptarmica*, double var.—W. C. 1, *Aralia chinensis*; 2, *Acauthus mollis*; 3, *Hydrangea hortensis*, garden var.; 4, *Cornus alba*, var. *Spethii*.—W. T. Johnson. 1, *Polygonum vacinifolium*; 2, *Commelina coelestis*; 3, *Scolopendrium vulgare*, one of the crested forms; 4, 5, 6, *Acer palmatum*, garden vars.; 4, being var. *dissectum*.—W. Thomson. 1, *Atriplex patula* 2 and 3, *Chenopodium rubrum*.

PEAT MOSS LITTER AND AZALEAS: B. B. Too spongy and absorbent of moisture, and we greatly doubt if the plants could be maintained in health in this material.

SIX SPECIES OF CONIFERS FOR PLANTING IN THE THAMES VALLEY: G. T. *Juniperus virginiana* (Red Cedar), *Pinus resinosa* (Red Pine of Canada), the Douglas Fir, *Picea excelsa* (common Spruce), *Tsuga* (*Abies*) *canadensis* (Hemlock Spruce), *Picea Menziesii*, *Sequoia sempervirens* (Redwood). These are fast growers, doing well in alluvial soils, provided there is no stagnant water. Only numbers of the trees planted together in woods or large clumps, would have any perceptible fragrance, unless the needles are rubbed or trodden under foot.

THE DROPPING OF THE SECOND CROP OF FIGS: B. B. In the absence of any information as regards the method of culture pursued, we can only guess the cause. Perhaps the temperature was unduly low at night, or cold water may have been applied at the root, or you may not have made use of bottom-heat. Figs in pots, and carrying fruit, are the better for being plunged in a hot bed of leaves or tan having a temperature between 65° and 70°.

TOMATOS: Dr. W. The fruits were solid and well flavoured, and if the plants crop abundantly, the small size of the former is no disadvantage.—T. & Both fruit and foliage are attacked by fungus, though different ones. Remove and burn the fruits as soon as you observe any are affected, and cut off all foliage that show any symptoms of disease. If this does not check its spread, remove the whole plant as soon as attacked.

TOMATOS AND ARTIFICIAL MANURE: H. E. T. Every 100 lb. of Tomato fruit takes from the soil about: nitrogen, 2.2 oz.; phosphoric acid, 0.9 oz.; potash, 4.6 oz. The nitrogen is equivalent to 14 oz. nitrate of soda. The phosphoric acid is equivalent to 5 oz. of dissolved bone-black. The potash is equivalent to 10 oz. of muriate of potash.

WIRE NETTING AND BUSH FRUITS: H. Hopkins. We do not believe that the drip will kill the bushes any more than would the rain. The drip will only occur for a short time after a shower. It is more likely that by preventing the small insect-feeding birds from approaching the bushes, the evil invited will be far greater than that you avoid, and both bushes and ground become infested with worms and insects in variety. If you put up the wire protection, the sides should be left open at such time as the bud-destroying and fruit-eating birds can do no harm to the bushes.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED, and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, and ALL CLASSES of GARDENERS and GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets and Weather, see page 12.)

THE

Gardeners' Chronicle.

SATURDAY, OCTOBER 9, 1897.

THE MANURING OF VEGETABLES AND HOPS.

THE members of the Permanent Nitrate Committee recently paid their annual visit of inspection to the Market Garden Experimental Station conducted by Dr. Bernard Dyer, under the executive supervision of Mr. F. W. E. Shrivell, F.L.S., on the Hop-farm of the latter at Golden Green, near Hadlow, Kent.

The station has now been established for four years, under a grant made by the committee, and the crops under experiment include several varieties of Cabbages, Brussels Sprouts, Cauliflowers, Broccoli, early and late Potatoes, Spinach, summer and winter Lettuce, summer Onions, Tripoli Onions, Leeks, Asparagus, Beetroots, Carrots, Parsnips, Jerusalem Artichokes, Globe Artichokes, Celery, Rhubarb, Strawberries, and Hops.

The experiments were devised by Dr. Dyer, at the request of the committee, in order to enable a satisfactory answer to be given to the question as to how far and under what circumstances nitrate of soda can be best and most profitably used as an adjunct to market gardening and Hop-farming, and how far it might aid in economising the dung of the farm, or in replacing the frequently enormous quantities of town dung purchased by market-gardeners. Six plots are devoted to each kind of vegetable under experiment. In every case one plot is annually dunged with fifty loads of London dung per acre, without artificials; while a second plot receives twenty-five loads of London dung per acre, also without artificials. Three other plots also receive the minor dressing (twenty-five loads per acre) of London dung, but this in each case is supplemented by phosphatic-manure and nitrate of soda, the dressings of the latter varying from 1 to 4 cwt. per acre; one half of each plot is also treated with potash salts. A sixth plot receives no dung, but is manured with phosphatic-manure and 4 cwt. of nitrate of soda per acre, one-half of this plot also being manured with potash salts. If the sub-division into potash and non-potash plots be taken into account, we thus have really ten experimental plots devoted annually to each vegetable. Every plot is annually treated similarly with regard to manuring, but a proper rotation of cropping is observed.

FARMYARD MANURE.

Dr. Dyer considers it desirable to accumulate further experience on a subject so altogether new, particularly as three out of the four experimental years have been marked by prolonged drought during a portion of the growing season, and he wishes to get

a better average of seasons before formulating specific directions based upon the experiments. Both he and Mr. Shrivell, however, are emphatic in stating that the general result of the experiments throughout was to show that the heavy dunging commonly practised by market-gardeners is altogether a mistake, being far too costly in proportion to the results obtained. They are convinced from their experience that it is in every way far more profitable to use, at most, half the quantity of dung ordinarily used, and to supplement it by artificial fertilisers. Indeed, in the case of the crops which have been least influenced by the dry weather, the most economical way has been found to be to dispense with dung altogether, relying entirely upon artificials, such as superphosphate or basic slag, and nitrate of soda and potash salts in suitable combinations; and they repeated the opinion they have formerly expressed that the only feature which renders the use of dung economically desirable is its mechanical action in helping the soil to hold moisture better than where dung is not applied. This mechanical property is of material assistance in dry weather, and on this account alone they consider that market-gardeners would be unwise to dispense with the use of dung, but so far as mere fertilising properties are concerned, they repeat their opinion expressed in former years, that, as a mere source of plant-food, dung is both expensive and inferior to artificial manures. They therefore recommend that in market-gardening the use of dung should be greatly reduced, and the use of artificial fertilisers largely increased.

NITRATE OF SODA.

The effect of nitrate of soda in conjunction with phosphates has perhaps been most marked on the various crops of the Cabbage kind, but there are few crops on which it has not produced remarkable and highly remunerative results. During the past summer the use of a moderate dressing (25 loads per acre) of dung, when supplemented by phosphatic-manure, potash salts, and 4 cwt. of nitrate of soda per acre, gave nearly 12½ tons per acre of sound, marketable Tripoli Onions, whereas a double dressing of dung (50 loads per acre) without artificials, produced less than 9½ tons; 25 loads of dung per acre without artificials produced only 8 tons per acre. While, on the other hand, the use of the extra 25 loads of dung only raised the yield by less than 1½ ton per acre, the use, on the other hand, of artificials in its place gave an increase of more than 4½ tons of Onions per acre. The use of a light dressing of dung in conjunction with artificials therefore gave a better result by 3½ tons per acre than was produced by heavy dunging, while the cost of the artificials was not much more than half that of the extra dung. Even on the plot on which half the quantity of nitrate was used, the yield was 1½ tons more than was obtained by heavy dunging. On the plot on which chemical fertilisers only had been used for four years in succession, without any dung at all, the yield was, notwithstanding a dry season, heavier than on the plot receiving the double dressing of dung, while the chemicals only cost something like £3 an acre, whereas the heavy dressing of dung cost £10.

STRAWBERRIES.

Referring to some of the other results obtained during the current season, Dr. Dyer points out that the best Strawberry plot gave an extraordinary yield viz., at the rate of well over 3 tons per acre. This produce was obtained on the plot annually dressed with artificials including 2 cwt. of nitrate of soda per acre, together with phosphatic manure (superphosphate or basic slag) and twenty-five loads of dung per acre. The plot dressed with twice the quantity of dung, without artificials, gave less by nearly 1 ton per acre, so that the artificials may be said in this case to have produced about 1 ton of Strawberries per acre.

The plot on which the larger dressing of dung was used gave a much smaller crop than that dressed with the smaller quantity of dung. The results of this experiment so far seemed to show that 2 cwt. of nitrate of soda per acre (together with phosphatic

manure and a moderate quantity of dung) is as much as can be advantageously given to Strawberries, the use of a larger quantity having perhaps caused a larger development of plant, but without producing so large a yield of fruit. With a dressing of 2 cwt. per acre no difference was found between the keeping-qualities of the fruit, as compared with that grown from moderate dung alone; nor was the very large increase obtained accompanied by any deterioration in flavour.

RHUBARB.

In the case of Rhubarb, the use of chemical fertilisers in conjunction with dung has, in the small or fine varieties of the plant, nearly doubled the crop, as compared with that obtained by dung alone, and even where chemical fertilisers, including 4 cwt. of nitrate of soda were used without dung, the yield was greater than that obtained by the double dressing of dung without the aid of artificials. In the case of the grosser varieties of Rhubarb, the proportionate increase was not so great, but the liberal use of chemical fertilisers raised the crop by 50 per cent., as compared with dung alone.

ASPARAGUS.

The use of nitrate of soda on Asparagus has proved highly remunerative, particularly on those plots on which potash salts have been used, in addition to phosphates. The judicious use of artificial fertilisers, in conjunction with dung, has doubled the weight of produce, the advantage being found not only in a very large increase in the number of heads cut, but also in their size and thickness. Almost equally interesting results have been obtained from most of the other crops experimented upon, and before very long Dr. Dyer hopes to draw many practical generalisations from the experiments, not merely as to the utility of artificial nitrogen and phosphates, but also as to the effect upon the various crops, of potash, a constituent with regard to which, on the same soil, some of the crops—notably those of the Cabbage kind—appear to be utterly indifferent, while on some other crops the effect is extraordinarily marked.

HOPS.

At this season of the year, however, the plots which attracted most attention were the Hop plots (then in course of being picked), where the plan of manuring is somewhat different.

An acre of Hops in one of Mr. Shrivell's Hop-gardens has been for the last three years divided into a number of plots, of which six have for the last two years received no dung whatever, but merely a mixture of artificials. In 1896, they received 8 cwt. per acre of superphosphate and 2 cwt. per acre of muriate of potash, supplemented by varying quantities of nitrate of soda; while during the present year they received 10 cwt. of basic slag per acre and 2 cwt. of sulphate of potash, also supplemented by quantities of nitrate of soda varying from nothing up to as much as half a ton per acre. A neighbouring plot was manured with dung only at the rate of thirty-three loads per acre. Dr. Dyer has now furnished the results of the experiments on the crop just obtained, which are as follows:—

Plot.	Manure per Acre, 1897.	Weight of Kiln-dry Hops per Acre.
A.	Basic slag, 10 cwt. Sulphate of potash, 2 cwt. Nitrate of soda, none.	Cwt.
B.	Basic slag, 10 cwt. Sulphate of potash, 2 cwt. Nitrate of soda, 2 cwt.	7½
C.	Basic slag, 10 cwt. Sulphate of potash, 2 cwt. Nitrate of soda, 4 cwt.	12
D.	Basic slag, 10 cwt. Sulphate of potash, 2 cwt. Nitrate of soda, 6 cwt.	13
E.	Basic slag, 10 cwt. Sulphate of potash, 2 cwt. Nitrate of soda, 8 cwt.	13½
F.	Basic slag, 10 cwt. Sulphate of potash, 2 cwt. Nitrate of soda, 10 cwt.	13
X.	33 loads dung only.	8

It will be seen that the use of nitrate of soda was profitable up to the extent of 8 cwt. per acre. On Plot F. the larger dressing of 10 cwt. per acre has not increased the yield further. It is to be noted that this is the third year in succession in which these plots have received similar dressings; and no doubt many Hop-farmers will learn with some surprise that as much as half a ton of nitrate of soda per acre can be used on the same ground for three years in succession without injuring the quality of the Hops. Last year the general growth of Hops was, as elsewhere, much more prolific, and plot A (which received no nitrate of soda, and no nitrogenous manure except what survived from the dung applied in an earlier season), yielded as much as 13½ cwt. of Hops per acre; and the use of nitrate of soda was able to increase this yield only as far as 16½ cwt. per acre. This result was obtained by the addition of only 2 cwt. per acre of nitrate, and any increase of nitrate last year failed to tell further on the weight of the crop.

This year, on the contrary, when the general growth of the crop was much less free and abundant, the increase obtained by the use of nitrate has been progressive throughout the series. Thus the 2 cwt. of nitrate produced a gain of nearly 2 cwt. of Hops, 4 cwt. of nitrate a gain of 4½ cwt. of Hops, 6 cwt. of nitrate a gain of 5½ of Hops, and 8 cwt. of nitrate a gain of 6 cwt. of Hops, after deducting in each case the quantity produced merely by the phosphates and potash, and by the previous dunging of the soil.

Some experiments on the manuring of a Nut plantation are also in progress.

NEW OR NOTEWORTHY PLANTS.

CATTELEYA SCHOFIELDIANA GIGANTEA ×
= *C. GRANULOSA* × *C. GUTTATA*
LEOPOLDI (nat. hybr.).

THERE is a considerable number of *Cattleya Schofieldiana* to be found all over the country, many of them of the ordinary type, but the subject of our illustration (fig. 75, Supplement) with the affix *gigantea* is an improvement, and one that is worth figuring in the columns of the *Gardeners' Chronicle*. It is a natural hybrid, bearing the character of the seed-bearing parent, *C. granulosa*, with the very prominent spotting of *C. guttata* Leopoldi. The form of the segments, particularly the petals, is like the shape of the moon about the end of the first quarter, each limb in form like a scimitar. Measured across the petals, the flowers had a width of 6½ inches, and measured from the top of the dorsal sepal to the end of the lip it is 5½ inches. Length of sepal is 3½ inches, and breadth 1½ inch. Length of petal is 3½ inches, width 1½ inch. The whole segments are of rich cinnamon-ground colour with a yellow margin. The crowds of orbicular spots approach a cerise tint. The petals are enlivened with a shade of reddish-purple, flushing over the cinnamon ground-colour, which contrast well with the pale yellow edging. The length of the lip is 2½ inches. The convolute portion is bluish-white, the blade contracts in the middle like that of *Leopoldi*, is crimson-shaded and lined, and the extremity of the lobe is white. That part of the convex-column seen through the orifice of the lip is yellow. The peduncle was four flowered, but the plant, when cultivated properly, is sure to yield more flowers. It is a vigorous grower, although that cannot be said of the type generally. The principal merit of the flower consists in its size and its vivid colouring, excelling *Cattleya Queen Victoria* (see *Gardeners' Chronicle*, 1892, pp. 808, 809), which variety has no spotting. Capt. Schofield tells me that the plant which flowered in his collection, and was named after him, got less and less every year until it disappeared.

Samuel Gratix, Esq., West Point, Whalley Range, Manchester (Mr. R. McLeod, gr.), to whom we are indebted for this illustration, is the fortunate possessor of the plant, *J. A.*

EUCRYPHIA CORDIFOLIA, Cavanilles.

This beautiful Chilean shrub, which we believe has flowered for the first time in this country during

the past summer, belongs to a genus which has been referred to several natural orders; Bentham and Hooker in the *Genera Plantarum* place it in Rosaceae; there are but four species. *E. pinnatifolia*, also a native of Chili, is figured in the *Botanical Magazine*, t. 7087, and has also been figured in these columns. This latter is apparently a much hardier plant than the subject of the present illustration (fig. 73), which was prepared from material supplied by Messrs. Veitch from their Coombe Wood Nursery. *E. cordifolia*, however, would be likely to thrive in the southern and western counties of Britain, &c., and is a valuable addition to the list of ornamental outdoor trees for such localities. In its native habitat it attains a height of from 30 to 50 feet, and its handsome, dark green, persistent foliage sets off to the best advantage its showy white flowers. Another species, *E. Billardieri*, from Tasmania, flowered in Kew some years ago, and was figured in the *Botanical Magazine*, t. 7200. This is by no means hardy in the neighbourhood of London, but would probably succeed wherever *Eucalyptus globulus* thrives. Like *E. cordifolia*, this has simple leaves. The fourth species, like *E. pinnatifolia*, has pinnate leaves; it was discovered on the Clyde River in New South Wales several years ago, but has not yet been introduced to cultivation. *G. N.*

ORCHID NOTES AND GLEANINGS.

YOKOHAMA.

THIS climate is so favourable for the cultivation of some things, particularly Orchids, that it is proposed to increase the collection, with the view of raising seed and seedlings in quantity of the latter. We can ripen seed in about half the time it takes in England, and in our Orchid-houses it is no uncommon thing to see Orchid seedlings springing up of their own accord, and without any attention whatever. We shall be able, therefore, in course of time, to introduce Orchid seed as an article of commerce—anyhow, we intend to try. *Miyata Shoten*.

ORCHIDS AT L'HORTICULTURE INTERNATIONALE E, BRUSSEL.

The blooming of the *Catacetrums* has commenced brilliantly; already, at the end of September, I noticed many fine flowers of *C. splendens* and *C. Bungeoethi*, all the specimens of this beautiful genus growing with surprising vigour. A variety of *Cypripedium Spicerianum*, found among an importation, is remarkable for its purplish-red standard and yellowish-green sepals. The very rare *Odontoglossum Kramerianum* is also in flower, and so are many plants of *Miltonia Moreliana*, remarkable for the extra dark colouring of all the divisions of the flower; a wonderful collection. *Cattleya Varjenskyana* is certainly very fine; *Lælia præstans* has twenty blooms, making it a very conspicuous species; the size and form of the flowers, the colouring of the lip, and of the divisions in general, should cause it to be widely sought after.

Vanda amœna has a blue lip, and brownish-grey divisions; it is a hybrid from *V. cœrulea* and *V. Roxburghii*—it will be figured in *Lindénia*. *Vandas* are now beautifully in flower. I would also mention *Dendrobium devonianum* very finely in bloom.

I would add, while on this subject, that the Exposition Internationale d'Orchidées, to be arranged on the first and last Sundays in November, will certainly be a complete success. *Ch. de B.*

THE SEED TRADE.

THE FOREIGN GRASS AND CLOVER CROPS.—Reports from the great seed-growing districts of Darmstadt and elsewhere do not appear to point to a general abundance, though of some leading articles there have been good crops; in general the expectations entertained in the early part of the summer have not been realised, although the yield is almost an average one. The spring weather was most favourable generally to the development of the plants; the produce of green fodder and hay was great, but the

production of seeds has not quite fulfilled the promise of the earlier part of the season. The two principal Bent Grasses (*Agrostis*) are a very mediocre crop, both in southern Germany and the United States, and as little if any was left over from last year, prices will rule high as they did then. The quality is better than that harvested a year ago. The turfy and waved Hair Grasses (*Aira cæspitosa* and *A. flexuosa*) have been harvested in satisfactory and good quality. Of Meadow Foxtail Grass (*Alopecurus pratensis*) there is a good crop, and the germinating power is excellent, but the seeds are found to contain what is known as the "red larvae;" and the presence of other impurities necessitates severe cleaning to secure high class samples—hence prices for these must rule high. Sweet Vernal Grass (*Anthoxanthum odoratum*) has yielded a fine crop of heavy well-matured seed, and the same can be said of its variety *Puellii*.

The Tall Oat-grass (*Avena elatior*) also shows a heavy yield. Its herbage is very productive, and it is said, that when growing with other grasses cattle and sheep eat it, but decline it alone, and appear to dislike hay in which it appears in any large proportion. *A. flavescens*, the yellow Oat-grass, has been harvested in extremely small quantities, and prices must be high. Cockfoot Grass (*Dactylis glomerata*) is largely grown for seed both in New Zealand and the United States; the former reports a medium crop, and fine bright samples are rare, half the crop, at least, being discoloured by rain. The crop in the United States is better both in quantity and quality. Crested Dogtail Grass (*Cynosurus*) is an average crop, the colour not so bright as could be desired, but the germination is good.

The Fescue Grasses, and especially the Hard and Sheep Fescues, have yielded abundant crops, though the quality of some is not satisfactory. Seeds, light in weight, and often greenish in colour, in consequence of the great heat which prevailed during the time the seeds were maturing. Severe cleaning is necessary, and as this means a considerable loss in bulk, superfine samples will be high in price. The Narrow-leaved Fescue has been produced in sufficient quantity, and of fine quality. Owing to over production during the last few years, the acreage of this grass in the United States was materially reduced this season; in consequence, prices are firmer, and a return to normal conditions is probable. A variety of Tall Fescue, known as *arundinacea*, though regarded by growers as distinct from the type, is not so accepted by authorities. The true form of this is said to be grown in southern Germany, and it has been produced in good quantity, though the seed is not, perhaps, so heavy as last season, and to obtain high-class samples a good deal of cleaning is required.

Lolium perenne, the British perennial Darnel or Ray Grass, is a good crop; and so is the Italian Ray Grass, *L. italicum*; the latter is of excellent quality. The United States report an excellent crop of Timothy Grass (*Phleum pratense*), and prices which were low are rising; it is a little too early to judge of the nature of home crops. The Meadow Grasses (*Poa*), are all showing good yields, the Rough-Stalked in particular is of excellent quality, and in the case of this grass there was this season a reduction of acreage, owing to low prices ruling; the consequence is, smaller bulks and increased prices.

Clovers show varying results—some plentiful, some less so. Sainfoin rules high in price, and it is expected will advance still farther. Two-cut Sainfoin has given a fair crop this year, and prices will rule high. Trefoil shows a heavy crop, and fine samples. White Clover is plentiful, but fine samples are scarce, only medium ones having so far appeared. Reports as to the crops of Alsike Clover, both from the United States and Canada, are not favourable, and the samples received are uneven. The crop in the Rhine country is being harvested; the crops are not large, but the samples are good. *Trifolium incarnatum* has been harvested in large quantities, especially in France, and prices are low. The crop of Lucerne from Provence is small, but samples are fine and bold. A failure of crop is reported from Italy, and the seeds are inferior in boldness and

FIG. 75.—CATTLEYA SCHOMBURGKIANA, VARIETY GIGANTEA.

Petals and sepals cinnamon-brown in colour, with a yellow edge, the former having a shade of reddish-purple; lip bluish-white, shaded crimson; and extremity of lobe white; interior of convex column yellow. (See p. 246.)

colour; prices are expected to be high. As to red Clover, it is not possible, as yet, to form an opinion, as so much depends upon the character of the weather up to the middle of October. Dry weather will produce fine seed from the Rhine country, and also from the Palatinate, where a large acreage of plants has been left for the production of seeds; from a few favoured spots have already come samples of fine bold grains. Reports from France are favourable in some districts, unfavourable in others; the latter from the south, the former from the north. America reports there will be a good crop; while

artificial assistance. Whilst *Chrysanthemum* fanciers take great interest in this section, so, too, do the market-growers who furnish to the public vast quantities of cut bloom; and not one whit less interesting is it for gardeners, who have to furnish fine floral displays in the autumn outdoors, and plenty of good flowers indoors. When I saw the collection some of the earliest were rather over. I did not regret that, because I do not care for August bloomers. Those may be correctly classed as summer varieties, but few *Chrysanthemums* are needed then. At no time of the year outdoors are they of more value than just about Michaelmas;

present seen, simply because nothing was known at the time of planting as to relative heights, tall and short are intermixed. Another year, of course, that can be remedied. Amongst whites, the very best undoubtedly is the new Mychett White, 16 inches in height, flowers Japanese reflexed, broad spreading habit, distinctly beautiful. Lady Fitzwygram, 18 inches, is free and good, though the flowers have too much infusion of yellow. Of course, Madame Desgranges is there blooming freely at 2½ feet in height. Longfellow has medium-sized, flat-petalled flowers, borne in good clusters,

FIG. 73.—*EUCRYPHIA CORDIFOLIA*: FLOWERS WHITE. (SEE P. 246.)

Russia will have no seed to export this season. Reports from Hungary, Bohemia, and Galicia are as yet uncertain; but it is expected the yields will be abundant. *Pisum*.

EARLY AUTUMN CHRYSANTHEMUMS AT CHISWICK.

For everyone interested in these hardy and useful plants, the extensive collection now growing on a long broad border in the Chiswick Gardens, should have exceeding value. These autumn bloomers are less pot than outdoor plants, and it is one of the admirable features of the Chiswick collection that it is not in pots, but planted out where the conditions of culture are natural, and no variety obtains any

and it was on September 24 that I saw the plants. There were, perhaps, one-half early or September bloomers, and generally of good, useful heights; the other half showed one variety of good height and of bushy form that would not be well in bloom until the middle of October, which is rather late, and the rest were too tall, loose-growing, and late, and of whatever worth florally, quite unfitted for outdoor blooming. None the less, all that may show good flowers and excellent colours, would, so grown during the summer, well repay the trouble if lifted and blocked in boxes, or singly into large pots, and placed under glass. Where it is desired to make masses of these autumn varieties, either in beds or borders, the Chiswick trial is useful in enabling the exact heights of each variety to be obtained. As at

white flushed pink, 2 feet in height; this is a very nice variety. Mrs. Cullingford is an old one, 2½ feet in height, branches freely; the flowers are of the old reflexed type, open white and fades off to a soft pink. Yellows are very effective, especially Flora, old and remarkably good; the colour is a lovely soft golden hue, 20 inches in height, very branching, and a first-rate variety of the Pompon section. Golden Fleece is early, 2 feet in height, with large Pompon flowers, in some cases getting over; but with later plants, very fresh and beautiful. Mrs. Hawkins and G. Wermig, both 2½ feet, are well known, but the former is much the more effective. A charming dwarf yellow-flowered variety is Canari, having a spreading habit at 15 inches in height; the flowers are small, but borne in exceeding profusion. La Viberta also has smallish flowers

borne most freely on branching plants, but is 2½ feet in height. Ivy Stark is an odd name for a variety, 2½ feet high, with flowers of Japanese form, colour golden-buff, just opening well. Samuel Barlow, 3 feet high, has flowers of a pleasing salmon-rose, petals long and narrow; it is a charming variety. Very good too is Madame Eulalie Morel, flowers having flattish petals of a bright rosy-pink colour, height 3 feet. A great beauty is Edith Syrett, having a surprisingly free-branching habit, blooming profusely, flowers of good size, narrow and tasselled petals, colour bright rosy-red; this is one of the very best. Mrs. Selby has a broad-branching habit, and blooms profusely, flowers like those of a pink Mdle. Marthe. White Lady, 20 inches, branching, and free, is good; the flowers are smallish, white-flushed pink, of good form. Mme. M. Masse has large Japanese flowers of a bright rosy colour; Lady Selborne, 3 feet high, has flowers of good size, colour chocolate-red, but discolours with age. Madame E. Lefort, 18 inches, has good-sized Pompon flowers, with flat petals, having serrated edges, is very free, colour old gold. Strathmeath, 2 feet, has medium-sized flowers of peach colour, makes a good head of bloom. Toreador is very early, blooms profusely, flowers deep golden-chocolate, but was getting over when I saw it. A great beauty just fairly well opening is Harvest Home, much like Tokio, petals long, of a rich red chestnut, with golden reverse, 2½ feet. Another good chestnut is Fred Pélé, 20 inches, very branching and free. The selection given does not exceed two dozen, but it is of the very best. Those who cannot visit Chiswick may accept this list as presenting the pick of autumn-blooming Chrysanthemums. A. D.

THE ROSARY.

THE ROSE SEASON OF 1897.

ALTHOUGH we are within three months of the end of the year, it is still possible to find good blooms, especially among Teas and hybrids of this race of Roses. The wood passed through last winter very satisfactorily, and the early spring had a promising outlook. But we were soon visited by frosts, excessively dry and cold weather generally, and more than the average number of insect pests. Weevils were most troublesome; so, too, was the stem-boring saw-fly. Many a promising shoot was completely ruined by these, and I know of more than one instance where the first crop of bloom was a failure from their ravages. Aphids and the green caterpillar were rather numerous in this district (Sussex), but our worst enemy here was the small, dark-coloured grub. It was most unfortunate that the lateness of the bloom caused by the crippling of the early growths by frost, should find us compelled to alter the date—already a very early one—of our first National Rose Exhibition, but the national rejoicings made it necessary to fix this a week earlier still. Under these circumstances none of us expected to find a really good show at Portsmouth, but the result was a most welcome surprise, as although several of our largest growers, both amateur and professional, were not even present, and many classes could not boast of a single exhibitor, the nett result was far beyond general expectations.

Almost immediately after this date we were favoured with "Queen's weather," and Roses improved rapidly. Sutton, Croydon, Reading, Gloucester, and other Rose shows were even beyond their usual degree of excellence; while the Crystal Palace meeting contained more blooms than at any other exhibition. Nor have our Roses been a disappointment at any time after the latter end of June; and, as already remarked, they are still much in evidence in almost all classes or sections. Most insect pests disappeared about the same date; while, changeable as the season has been, mildew was by no means so prevalent as might well have been feared. Orange-rust, and the dark blood-coloured spots upon foliage that seem so intimately connected with this disease, were rather more troublesome than usual, and much of the leaf fell; but with better weather, copious showers, and a

warm soil, Roses soon replaced this, and were once more in full growth and bloom.

When making my comments upon the Rose season, I have generally alluded briefly to those individual blooms which secured the Silver Medals of the National Rose Society at that Society's exhibitions. It is interesting to note that both old and new varieties were equally represented during the past season. We have Niphetos winning at Norwich (one of the most magnificent flowers ever staged), a Rose sent out so long ago as 1844; while a Rose only sent out last year was successful twice. I allude to Muriel Grahame, one of the several good sports from another old Rose (Catherine Mermet, 1869), that frequently comes well to the fore. Mrs. John Laing, a Rose introduced in 1887, was also successful twice, the others being Lady Mary Fitzwilliam, Comtesse de Nadaillac, Madame de Watteville, Madame Cusin, Horace Vernet, Kaiserin Augusta Victoria, and Earl of Dufferin.

Among new Roses, Messrs. A. Dickson & Sons were again the successful competitors for the Gold Medal, winning it this year with H.P. Ulster, a very large and full bloom, but which has been described many times this season. The most remarkable Rose of the year is Empress Alexandra of Russia, a Tea that possesses good habit, and is free blooming. I have seen it grand from under glass, and to-day (Oct. 2) I cut three good blooms from a dwarf in the open. It was only distributed this summer, and from such a tiny specimen as the one I received, I have cut nine or ten blooms. It strikes one at once as being thoroughly new and distinct.

I did not purpose mentioning many varieties, but several of the newer Hybrid Teas have been so good and constant in blooming, that they really deserve naming. These are Antoine Rivoire, Marjorie, Mrs. W. J. Grant, Kaiserin Augusta Victoria, and Mrs. W. C. Whitney. Tom Wood and Laurence Allen have been the best H.P.'s of last season's introduction; while Mrs. Pierpoint Morgan, Sylph, and Muriel Grahame from the Teas have also been very good and consistent, especially the two last named. The rains came just in time to secure a prolonged and successful season for budding, and all classes of stocks have a very promising look. The hedge-Briar could not look better, and, generally speaking, the buds have taken well. A. P.

FRANCE.

M. LEMOINE'S NURSERY AT NANCY.

THE guide-books tell us, with more or less accuracy, this, that, and the other thing about Nancy; but not one of them, so far as we have seen, says one word respecting the circumstance which renders this town specially attractive to the horticulturist. In our turn we shall be just as eclectic. We shall pass over, without mention, all the other attractions of the Lorraine capital, and ask the reader to accompany us at once to the nursery of M. Lemoine. M. Lemoine is a Veitchian medallist, having grandly earned that distinction by the number and importance of his experiments and introductions. We shall not detain the reader very long here, but those who follow our footsteps and visit the nursery should be prepared for a long stay, as the number, variety, and interest of the plants to be seen demand a lengthened visit. Perhaps it is as well to say at once that the main interest consists in the wholesale way in which hybridisation, breeding, and selection have been carried out. Consequently, whilst the horticulturist pure and simple will be charmed with the diversity and quality of the stock, the physiologist and the evolutionist will find such a mass of detail suitable for their purpose, that should the University found a chair for the purpose of studying and diffusing information concerning variation, and the causes influencing it, here is the experimental ground ready to hand. Such is the variety of objects, and so numerous the experiments, that we know not where

to begin; whilst, as for the finish, that must be determined more by consideration for the reader's patience than by the subject itself.

Let us begin with the Begonias. Everyone knows how large a share M. Lemoine has had in the development of the tuberous Begonias. There are quantities here mostly going out of bloom at time of our visit (September 24); but our attention is drawn to a whole race of sweet-scented varieties. The delicate perfume, which is like that of *Lem*, is evanescent, but while it lasts it is unmistakable and not confined to flowers of one colour, but, as have said to numerous forms, all as we were derivations from B. Baumannii. Next them a group of crested Begonias, presenting the same growth or fringe as occurs on the plants of one variety Cyclamen. Indeed, it is hard to say what variety may not be expected from the Begonia. Nor is the mutation confined to the tuberous section, for there are very free-flowering semi-double varieties, from Begonia semperflorans, and others from B. L. tiana and its variety grandiflora.

Pelargoniums form another of M. Lemoine's specialties, and one of his objects at the present time is the production of *Picotee* varieties (*picotee* the ground colour of the petals being sprinkled with minute dots of a darker colour. Whether this is improvement or no must be left to individual taste to determine, enough for us to note that M. Lemoine having willed their production, here they are.

Heliotropes are grown as annuals, the seeds sown in May. As we saw them, the flowers were densely compact, of different colours, powerful fragrance, and diverse habit. These originated a cross between H. incanum and a form of peruvianum.

Hybrid Fuchsias abound, appealing to the taste of the specialists; time and space will only allow us to note crosses in which F. myrtifolia has taken a part, and others the result of a cross between F. phylla and F. splendens.

Another remarkable hybrid has been raised between *Russelia juncea* and *R. sarmentosa*. The plant cut back, so as to secure an abundant formation of new shoots, every one of which flowers at the tip.

Numerous forms of *Abutilon* call for notice; perhaps even more striking are the endless series of varieties of *Montbretia*. Often does it happen to be called on to name a *Montbretia* for a respondent. Books are referred to, specimens confronted, plates scrutinised, but as often as no definite answer can be given. The reason becomes apparent in this nursery. The area devoted to the culture is very considerable, and the number of forms apparently illimitable. There are double forms, single forms, spotted forms, forms without spots, forms of a pale primrose colour, others deep orange red, with every intermediate tint. Some have funnel-shaped flowers, others have flat, star-shaped blooms, and another set has the perianth-segments reflexed as in the Martagon Lily. We no longer wonder we find it difficult to name a *Montbretia*. Some of the varieties are subject to the attacks of a fungus, probably a *Peronospora*; but the dipping the blooms in the *Bouillie Bordelaise* is found sufficient to check the disease in check, whilst diseased plants are destroyed, and none allowed to leave the premises.

Scarlet *Salvias* add their share to the brilliant garden. There are many varieties, but called *Précoce de Chrétien* is found to be the best for bedding purposes, being fifteen days earlier than other varieties.

Of *Anemone japonica* the forms are numerous. *A. elegans* is still perhaps the best of the varieties, though one called *rosea superba* has large flowers. Of white varieties, Lord Ardilaun is the best. Coupe d'Argent and Couronne virginie dwarf forms, with double flowers. Whilst with usually more or less deformed flowers, it is attractive than some others. To see these plants at advantage they require space, and to be placed here, side by side, when their comparative merits may be adjudged. It is a curious thing that, of some of the older varieties do not mature their

the newer ones do so freely. This is a fact of which the student of evolution will do well to take note.

Of *Gladiolus* we are almost afraid to speak, so great is their number, so truly superb their appearance, even towards the end of September, when most of them have passed their best. If we were to say what we thought, or even transcribe what was hurriedly jotted in our note-book, we should lay ourselves open

sort is, however, dispelled here. The two have been crossed and re-crossed till the distinctions are extinguished. M. Lemoine himself told us so, but he gave us a hint which may be useful to others—the tendency in the flowers of *G. Lemoineanus* is to have the lower perianth segments blotched, whilst the corresponding parts in the *Nanceianus* breeds are sprinkled with small dots of colour. The hardihood

plants and hardy trees and shrubs absorb at least as much of his attention. The best and most curious are selected, and wherever possible they are crossed and hybridised. A flowering-plant is not long in M. Lemoine's possession before its capabilities in this way are put to the test. Of some of these trees and flowering-shrubs we must speak on another occasion.

(To be continued.)

FIG. 74.—HIBISCUS MANIHOT; FLOWERS SULPHUR-YELLOW, DEEP PURPLE EYE.

to the imputation of exaggeration. Moreover, to do justice to these superb plants, the writer should be a specialist. Let us simply say, the appearance of the quarters, even at the end of September, was one of indescribable magnificence. But oh! these raisers; how they do confuse us! Once we thought we knew the difference between the races known as *Nanceianus* and *Lemoineanus*. Any complacent feeling of that

is not impaired with all the change that has occurred. Other hybrids from *G. papilio* and *G. dracocephalus* were shown us, but to specify is impossible. For the same reason we must pass with the mere mention the brilliant *Phloxes* and the extraordinary *Pentstemons*, the biggest and finest we have seen.

It must not be supposed that florists' flowers form the only objects of M. Lemoine's care, greenhouse

HIBISCUS MANIHOT.

EITHER this is a very variable plant, or several species are confused with it. The plant shown by Mr. Fulford, gardener, Moor Hall, Cookham, at the Drill Hall (see fig. 74) on September 7, 1897, and Certificated by the Royal Horticultural Society, differed widely from the plant grown in the Tem

perate-house at Kew under this name. Nor is the Kew plant annual, the example under notice being about ten years old. It is cut down early in spring, and by the autumn it makes shoots 6 feet or so high, as thick as a man's finger, and it develops terminal and axillary racemes of flowers in September, being finely in flower now. The largest leaves have petioles 18 inches long, a pedately lobed blade 18 inches across, the lobes irregularly notched or toothed. Both petiole and blade are [thinly] clothed with soft, very fine hairs. In habit and leaves the plant resembles a vigorous Castor-oil plant, save that it is of a uniformly dark green colour. The flowers are fully 6 inches across, their colour being clear sulphur-yellow, with a maroon eye-like blotch at the base. The peduncle is 2½ inches long; the calyx-lobes, of which there are four, are over an inch long, by three-quarters of an inch broad at the base. The flowers last only a day or so, but they are borne in large numbers and in quick succession. For a large greenhouse this plant is worth attention. It is ornamental even when not in flower. It thrives better when planted in a border than when grown in a pot. W. W.

[We believe that this is a very variable plant, and it is possible that some might consider more than one species included under the same name. That is not our view, nor has the inspection of the plant growing in the temperate-house shaken our conclusion. The species seems distributed throughout the tropics of the Old World, but whence it originated is not clear. It is said to have been introduced from China, but the species is not enumerated in Forbes' and Hemslay's *Enumeration of Chinese Plants*. In the monograph of *Malvaceae*, contributed to the *Flora of British India* by the present writer, it is not recognised as a wild Indian plant (see vol. i. 1875, p. 341). It is not mentioned in Roxburgh's *Flora Indica*, nor in the *Flora of Tropical Africa*, nor in Mr. Baker's *Flora of Mauritius*, nor in Grisebach's *Flora of the West Indies*. On the contrary, it is included as a native plant in Franchet and Savatier's *Enum. Plant. Japon.* (1875), i., p. 64, and in the flora of Queensland (*Bentham Flora Aust.*, i., 209). Linnaeus, of course, could not have known of this locality. Probably a search through some of the pre-Linnaean books might afford some information, and also give the explanation of the name *Manihot*, also applied to an Euphorbiaceous genus. Evidently there are some interesting historical details to be unearthed when time and opportunity permit. In the meantime, we can admire the loveliness of the flower, and, although it is of no use for cutting, few things confer greater beauty on the warm greenhouse. We hope Mr. Watson will contrive to fertilise the flower, and secure perfect seed for botanical, as well as for cultural, purposes. It has been cultivated in this country, according to the *Botanical Magazine*, since 1712, at which period it was sent to the Royal Society as one of the fifty specimens then required to be delivered annually to that Society by the Society of Apothecaries. Ed.]

FRUIT CROPS OF GREECE.

It is needless to say that all our readers are in one way or another interested in the commercial success of the Hellenes, and as fruit forms a large item in products and exports, some facts in relation to this subject must prove interesting, especially when we state that the accompanying information may be considered to be official.

The fruit crop of 1897 has just been successfully gathered and stored. The principal fruit, as is well known, is Currants, and a small quantity of Sultanias and Figs is also procured; but referring to Currants, the crop of this season is estimated at 130,000 tons, against 145,000 last year, and 170,000 tons in 1895; the crop of 1894 being about the same in weight. Between the two latter amounts and the previous two, and principally to the first, there is a great difference, and this is due to a variety of reasons; firstly, to adverse weather during the maturing seasons; secondly, to inferior cultivation, which the growers were obliged to give since 1893, when, owing to large crops, the prices fell to starvation point. The Vines,

weakened by over-cropping, soon felt the effects of bad weather, which brought on the disease caused by *Peronospora*. The third cause, was that, owing to the non-remunerative prices, new plantations have been stopped, and the ruined trees have not been renewed.

The Currant crop previous to 1890 did not exceed 120,000 tons, but the unexpected and continually increasing demand, which had begun a few years previously in the French market, induced the owners of land to plant Currants as fast as they could. This appears to have been a great misfortune for Greece, for since 1890 the commercial community had to deal with crops varying from 155,000 to 175,000 tons; meanwhile the French market, which took 80,000 tons, for several reasons rapidly reduced their demands, and nowadays it seldom requires more than 5,000 to 10,000 tons. It was indeed a troublesome time for Greece, and one of the principal causes of her financial failure. Previous to 1891, the income of the country for crops of 120,000 tons was worth about £2,500,000, and, in an indirect way, perhaps another £500,000 from the lands which were afterwards used, to bring the crops to 170,000 tons the price of which fell so low that the value reached only £1,000,000 during the years 1892 to 1896.

Since the last-named year, the position has commenced to improve; the crops are becoming smaller; and further, the Government, yielding to the wishes of the growers, has passed a law by which 15 per cent. from the quantities intended for export is retained in the country and stored in Government warehouses—being gradually sold to distillers in the country at prices so low as to cover only expenses.

How the Vine disease was coped with need not here be referred to, and we can only add the hope that soon the revenue may be notably increased—it will be needed. E. C.

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorset.

Cypripediums.—The earlier-flowering varieties of the warm-growing *Cypripediums* have made considerable growths, and such plants as *C. Lawrenceanum*, *C. Stonei*, *C. Lowii*, *C. Curtisii*, *C. Swainianum* ×, *C. barbatum*, *C. callosum*, *C. ciliolare*, *C. Druryi*, *C. Masterianum*, *C. Rothschildianum*, *C. superciliare* ×, *C. Dominianum*, &c., that are in a pot-bound condition, should be repotted. When cultivated in a suitable temperature, these *Cypripediums* thrive luxuriantly, but many of the strong-growing varieties are greatly injured if kept in the same pots too long. Owing to the large quantity of water they require, the compost quickly becomes sour. When repotting well-rooted plants, put them in pots at least two sizes larger than those they now occupy. The pots must be well drained, and the compost may consist of rough fibrous peat and clean picked sphagnum in equal parts, adding some broken pieces of brick or tufa rock. There is no need to elevate the plants above the rim of the pots. The best position for the plants is one on the shady side of the East Indian-house, where plenty of light but no direct sunshine may reach them. Give them abundance of water at the root throughout the year. Such varieties as *C. "T. B. Haywood"* ×, *C. euryale* ×, *C. radiosum* ×, *C. orphanum* ×, *C. Pollettianum* ×, *C. ceno-superbiens* ×, *C. cenanthum* ×, and its variety *superbiens* ×, *C. Maynardi* ×, *C. picturatum* ×, *C. Harrisianum* superbum ×, *C. Ashburtoniae* expansum ×, *C. Io grande* ×, *C. purpuratum*, and others that are now in bloom should be repotted, or re-surfaced, with fresh material soon after the flowers fade. The dwarf-growing *Cypripediums*, as *C. niveum*, *C. concolor*, *C. bellatulum*, *C. Godefroyae*, and its distinct variety *leucoclitum*, cause many growers much trouble. Newly-imported plants will thrive well for a time, but afterwards they gradually deteriorate. The cause of failure is frequently that of growing them in too high a temperature, at the same time giving them too much water at the root. At this season, if the plants be kept in the East Indian-house, the growths frequently turn black and decay; and I find it better to remove them to the Cattleya-house, to a position where the foliage is within a foot or so of the roof, and where they will be but thinly shaded. During autumn and winter do not water the plants immediately the compost becomes dry, but allow them to remain dry at the

root for several days, even if the atmosphere surrounding them be arid; and if the house is naturally moist, a week or more without water will do no harm. Always avoid water lodging in the centre of the growths, or in the axils of the leaves. All hybrids from the above species are also liable to injury if watered indiscriminately during the same period.

The Cool-house.—*Odontoglossums* *Rossii*, *O. asperum*, *O. Humeanum*, *O. Galleotianum*, and *O. Cervantesii*, are now growing freely, and must be supplied with abundant water at the root until growth is completed. The same remarks apply to the *Sophronites grandiflora*, but this species should be placed at the warmest part of the house, and instead of suspending it from the roof as is usually done, let the plants be put upon a side stage where air is freely admitted, but where there is no draught. Arrange the plants upon inverted pots to bring them a trifle above the foliage of the *Odontoglossums*. Give them plenty of root-moisture, but do not keep them in a saturated condition. Repot *Sophronites grandiflora* and the above-mentioned *Odontoglossums* immediately after the flowers fade.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Coe's Golden Drop Plum.—Fruits of this excellent late dessert Plum still hanging upon wall-trees will ripen better if they be picked and spread out on a fruit deep in a shallow tray, and then placed on a shelf near the glass in a late Melon-house or vinery, putting a sheet of white tissue-paper over the fruits to prevent them being disfigured by the action of the sun. The fruits when thus covered assume a richer golden colour, and the flavour is improved by the warmer temperature of the house. Fruits of the variety *Reine Claude de Bay* taken from trees on north-west walls should be treated similarly.

Artificial Ripening of Pears.—It is many years since I pointed out in the *Gardeners' Chronicle* the advantage of artificially ripening some varieties of Pears, in order to maintain a good succession of dessert fruits. The method of procedure which I practised, and recommended, is as follows: gather the Pears when dry, place a little fine wood-wool or cotton-wool in the bottom of a Peach-box, covering this with a sheet of tissue-paper, and on this place the Pears closely together, one deep, covering with another sheet of tissue, and a coating of wool sufficiently thick to exclude light and air from the fruit when the lid of the box is tied down. Afterwards, place the box or boxes on the hot-water pipes in a forcing-house, in a melon-house, or a vinery, in which the fruit is approaching maturity, according to the stage of growth at which the Pears have arrived and the urgency of the demand. In this way I have had good supplies of *Marie Louise* Pear, fine in quality and colour, ripe for weeks before the fruits of the same variety from the fruit-room shelves were fit for use, thereby extending the supply of this delicious Pear for several weeks. Knowing by a sorry experience how difficult it is sometimes to maintain a good and regular supply of dessert Pears, I consider the present an opportune time to call attention to the matter, in the hope that the hints thus given may prove useful. Two or three days will sometimes be long enough to ripen Pears treated as recommended above.

PLANTS UNDER GLASS.

By G. H. MARROCK, Gardener, Luton Hoe Park, Luton.

Freessias.—The earliest growth of these bulbs will require supporting by thin sticks and neat ties of bast or raffia, losing no time in getting the work done before they get prostrate. Those plants which are to flower at the end of December should now be afforded a warmth of 65° by day, and 60° by night, placing them in the sunniest position possible, and plying the syringe freely amongst them twice daily.

Clerodendron Balfourianum.—Any potted specimens of this handsome species of *Clerodendron* may be placed in a part of the intermediate-house exposed fully to the sun, in order that the wood may be thoroughly matured, turning the plants round once a week.

Palms.—The Palm-house or other structure should now be set in order for the winter, washing the roof and side-glass, and the stages, if any. Afterwards, let the plants be re-arranged, after cleaning each with a sponge and some kind of insecticide. When every plant is cleaned and put into its place, apply the XL All Vapour twice a week, in order to kill the stray thrips which may have escaped the cleaning; the advantage to be gained by freeing Palms from insects at this season is that the latter are more readily kept

from increasing in dangerous numbers during the winter when fire heat certainly tends to further their propagation. Palms should not be often disturbed at the root, but if any should require new drainage, or new pots or tubs, there is no harm in attending to their requirements at this season, provided no more disturbance of the roots takes place than can be avoided. After such operations as re-tubbing, &c., apply the syringe twice a day, and do not be very lavish in admitting outside air. Soot and sheep's manure form a good kind of manure for such of them as have not been disturbed, or which have only received a top-dressing, and may be applied as a clear liquid if mixed with water and decanted after a few hours. Small plants of *Cocos Weddelliana* and *Geonoma gracilis* should be grown in some quantity, these being very useful subjects for standing in small vases on the dinner-table. They may be placed at the warmer end of the house, and in order to keep the leaves fresh-looking, the pots may be plunged in cocoanut fibre refuse.

Selaginellas.—Pieces of *S. denticulata* and *S. densa* may be dibbled sparingly over the surface of the Palm-tubs and pots, and given encouragement to form a carpeting which is not accompanied, so far as I have noticed, by any evil results. Some growers use *Ficus muscosa* for the same purpose; it is, however, rather coarse-looking, and robs the soil too much.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maldenhead.

Evergreen Trees and Shrubs.—The planting and transplanting of a variety of trees and shrubs may now be taken in hand, and where planting on an extensive scale is being carried out, it should be commenced at the earliest possible moment. After the rains of the past month, this kind of work may be carried out with the certainty that with ordinary care the plants will succeed, and make a certain amount of growth next season. The success that has attended the planting of Conifers at Dropmore, is due largely to the early planting which has been practised here for many years. Some of the finest trees now standing were planted in the month of September. In transplanting Conifers and other trees larger than the usual size sent out by the trade, a good ball of earth, undisturbed if possible, should be taken with the roots; and any roots extending farther than the sides of which should be kept intact, and wrapped in wet straw till planted. The mass of soil should be kept together by means of small tub-staves roped round; or in the case of balls of only 2 to 3 feet diameter, wrapped tightly round with mats or sacking. The actual transference from one spot to another may take place on a strong hand-barrow, a mason's truck, or a 3-foot square sheet of iron, fitted with rings, to which men or a horse can be attached. This last is a very handy method, the sheet being readily slipped under a ball after it is bound up. These answers for ordinary planting; and for the transplantation of large specimens, specially-constructed machines have to be used.

Pinks.—Pipings struck in frames will be ready for planting out, and the earlier that this is done the better established will the plants become before the winter. If planted in beds, the ground should be dressed with rotten manure and a sprinkling of soot, and then deeply dug. Having chosen a time when the surface is dry, level the ground and make it firm in readiness for the plants. Pinks look nice in the herbaceous borders, and the positions for them should be similarly prepared. Where the edging to such bed is of stone or other hard materials, they may be planted a few inches from it, and be allowed to grow over, and partially cover it. Mrs. Sinkins and the old white Pink are useful varieties for this purpose. In beds or groups of half-a-dozen plants, 9 inches apart is far enough for planting Pinks.

Physalis Alkekengi (Winter Cherry) and the newer and stronger-growing *P. Francheti*, are effective subjects in the borders at the present time. If the growths are cut whilst in good condition and dried, similar to *Helichrysums*, they form useful decorative material.

Marguerite Carnations which were raised from seeds sown in the spring and grown in the open during the interval, should now be full of expanded flowers and flower-buds, which, if it be thought desirable, may be lifted with good balls, and after careful potting, stood in a cold frame and kept rather close for a week or two, shading them from bright sunshine till partially re-established. Before the winter let them be placed in an intermediate-house.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leicestershire.

Figs.—Indoor-Figs will mostly be over for the season, and that being so, the Fig-houses may be thrown wide open whenever the weather is not frosty. The foliage is very susceptible to frost, and falls off prematurely if exposed to it in October, which is not good for next year's crop of fruit. Weak shoots may be cut out, and the points of the shoots that do not touch the roof-glass may be left alone, it being a good practice to let the points turn up to the light. The Fig requires water at the root at this season, but not to have the soil saturated, as the Peach does. If a Fig-tree be growing strongly in the early-house, if the leaves are falling, it may be root-pruned, and even lifted, and have all the soil shaken from the roots; and after removing the badly-broken ones, and the toes of all the others, plant forthwith in mellow loam broken moderately fine, lime-rubble and sandstone. Manure is scarcely needed if the loam be of good quality, and contains plenty of fibre, excepting in the form of liquid or top-dressings when a tree is carrying a heavy crop of fruit. After re-planting, afford the soil a moderate application of water, and sprinkle the tree overhead for a few days, that is, till the roots enter the fresh soil. The plants in the late Fig-houses should now be denuded of all visible fruits, excepting those that are ripening. At Eastnor, small Figs of good flavour are being gathered from trees in the second or intermediate Fig-house; but gatherings must soon cease, or the trees will be unduly exhausted.

Strawberries.—The potted plants should have all runners pinched off, and the crowns reduced to one or two. Arrangements must now be made for putting the plants in frames and pits, where they may be protected from rain and frost. Failing frames and pits, shutters formed of tarred roofing-felt is a cheap and handy substitute, and if given a coating of gas-tar they will last for several years. Before putting the plants into winter quarters, afford them a thorough application of soot and lime-water which has been allowed to get clear, which will have the effect of driving the earth-worms present in the soil to the surface. Strawberry plants should be fully exposed when there is no hard frost, snow, or heavy rainfall, and the pots plunged to the rims in a bed of coal-ashes or leaves, so as to prevent loss of pots by frost.

Tomatoes.—Remove the leaves from all plants that will soon be rooted up, in order to allow the sun to reach the fruits, likewise removing all side shoots from plants that are to fruit in the winter.

THE KITCHEN GARDEN.

By W. FORK, Gardener, Highclere Castle, Newbury.

Asparagus, Seakale, &c.—If Asparagus, Seakale, Rhubarb, &c., have to be furnished at an early date, special preparations should be made whilst there is time, so as to render the plants more eligible for being forced, when in the ordinary course of things they should be quiescent. As regards Asparagus, which will have to be forced in pits and dung bed frames, it is of importance to apply special treatment to the earliest batches. For example, the plants should not have been robbed of any of their shoots during the current year, which will have had the effect of bringing on early maturity, and making a difference of several weeks as compared with plants which have been furnishing heads for the kitchen. Given strong clumps thus prepared, a failure is well nigh impossible. To force Asparagus, a half-spent Melon or Cucumber-bed fulfils all requirements, if a small quantity of fresh tree-leaves be added to stimulate the warmth still remaining in the old materials of the hotbed, care being taken not to add so much fresh material as to cause very strong fermentation. As will be understood, more heat is needed before the new year than afterwards. If hot-water pipes are not available, recourse must be had to linings of tree-leaves, with some amount of stable litter, so as to ensure a steady, genial warmth for a month or six weeks. It will be scarcely necessary to give minute directions as to the placing of the roots on the bed, although it may be well to state that the roots should be placed on a layer of a light kind of soil or half-rotten leaves, so as to separate them from the hotbed, and a sprinkling of fine soil tucked in round about and over the crowns, a heavy application of tepid water being finally given to settle the whole. The bed should then be finished off with fine light mould, laid 3 inches thick over the crowns.

Seakale.—In order to obtain the earliest produce, Seakale-roots should be taken up and planted rather thickly in pots or boxes, and placed on bottom-heat

in a warm, darkened shed or Mushroom-house. The roots should be divested of the remaining leaves, and left on the ground exposed to the sun for a week or ten days before being potted and placed in heat. This sort of treatment, and especially if slight frosts intervene, ensures a better start than would have been the case if transferred direct from the ground to the forcing-house. The new variety of Seakale, *Little Wonder*, is superior to the old Purple for early forcing—at least, this is what I find it is here; it being less hardy, a slight covering of litter should be laid on the crowns as soon as sharp frosts occur.

Rhubarb.—The Apple-crop being a poor one this year, forced Rhubarb will be more than ever in demand in the kitchen, and preparations should at once be made accordingly. The leaves should be allowed to die down completely in a natural way before disturbing the roots, and the crowns should be cleared of everything that has collected about them, thus exposing them to the sun. A warmth of not less than 60° will be required to start Rhubarb-roots into growth in late autumn, but no bottom-heat is required to keep up a regular supply, and in order to meet the demand they should be dug up at intervals of two to three weeks; or, if forced in the open quarters, the forcing-pots should be put over the roots, and warm dung and leaves placed around and over the pots. If the roots have to be dug up and forced indoors, it is prudent to cover the crown and the intervening ground between the lines of plants with stable-litter or tree-leaves to a depth of 5 or 6 inches, so as to exclude frost; otherwise, in severe weather it might not be possible to lift the roots when required.

THE APIARY.

By EXPERT.

Feeding the Bees, &c.—The month of October ought to see the bees fed where requisite, and all preparations for winter attended to, such as painting hive covers, many having been made leaky by the continued dry weather. Chaff cushions need making, and old ones repaired; and when examining the hive for the queen and the brood, winter passages may be made, or an oblong hole cut in the quilt, over which the cake of candy may be placed later on without disturbing the bees. The apiary that is put in good condition this month, will probably come out best next March. I most strongly advise that all syrup given be medicated, whether foul brood is known to exist in the locality or not. Prevention is easier than cure, and the cost of medicating is merely nominal. Feeding will not be required to any great extent this year, yet many will no doubt use the "Rapid," or box-feeder; indeed, we advise all with over half-a-dozen stocks to do so in preference to pottering with small bottles; they will greatly assist in keeping down the tendency to rob, which is sure to develop when feeding is carelessly done. Besides, a good box-feeder holds about half a gallon of syrup, and requires filling once, or at the most, twice, to give all the food needed. If set on the hive in the evening while the weather is still warm, the feeder will be emptied in a few hours, and no excitement whatever caused among the bees. Our own plan is to arrange the feeder while empty, and see that there is no access to it, except for the bees of the stock which is being fed. I then pour in warm syrup, cover up, reduce the hive entrance to an inch in width, and leave it. The following morning I usually find the feeder empty, and the bees perfectly quiet.

Robbing.—The great thing to be guarded against in autumn is what Americans call the robbing "boom," and although much mischief may arise if it occurs, it is nearly always brought about by carelessness, therefore avoid everything likely to induce a beginning to rob; feed only in the evening, keep entrances reduced in width, see that no syrup is within reach of flying bees. If hives are threatened with special attack, smear carbolic acid round the entrances; do not open the hives more frequently than can be avoided, and do it in the evening if possible; pay special attention to weak stocks, and join two together before feeding up; finally feed, and feed well! It will pay to do so.

Queens.—Examine the hives to ascertain if all the young queens are right. Lose no time requeening such stock as have old and worthless ones. If done at once, a good batch of brood may be raised from the new queen during the weeks when feeding is going on. In this case, of course, a slow stimulating feeder is used instead of the "Rapid."

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	OCT. 12	Royal Horticultural Society's Committee.
		National Chrysanthemum Society's Second Show (8 days).
		Annual Dinner of the United Horticultural Provident and Benefit Institution, at the Holborn Restaurant.

SALES.

MONDAY,	OCT. 11	Bulbs, at Protheroe & Morris' Rooms.
		Bulbs, at Protheroe & Morris' Rooms.
TUESDAY,	OCT. 12	Asaleas, Palms, Roses, Greenhouses, &c., at Protheroe & Morris.
		Roses, Fruit Trees, and other Stock, at Arches Farm, Framfield, near Uckfield, by order of Messrs. W. Paul & Son, by Protheroe & Morris.
WEDNESDAY,	OCT. 13	Bulbs, at Protheroe & Morris' Rooms.
		Sale of 100,000 Fruit Trees, at Perry Hill, Cliffe, by Protheroe & Morris.
THURSDAY,	OCT. 14	Bulbs, at Protheroe & Morris' Rooms.
		Stove and Greenhouse Plants, &c., at Protheroe & Morris' Rooms.
FRIDAY,	OCT. 15	Nursery Stock at the Arboretum Nurseries, Isleworth, by order of Messrs. C. Lee & Son, by Protheroe & Morris.
		Bulbs, at Protheroe & Morris' Rooms.
		Orchids at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—51° 4'.

ACTUAL TEMPERATURES:—

LONDON.—October 6: Max., 56°; Min., 48°.

PROVINCES.—October 6 (6 P.M.): Max., 55°, at Valentia; Min., 48°, at The Skaw.

DESPITE its funereal associations, and the dark colour of its lustrous foliage, the Yew commands a very large share of popular attention. It looks as if it might be, as it really is, the descendant of a very long line of ancestry. Moreover, the individual trees inherit length of days, so much so that, setting aside the Oak, there are few trees that can claim such an antiquity as the Yew. The flowers are generally on different trees, males on one, females on another; but, as in all such cases, the general rule admits of particular exceptions, and we find sometimes flowers of both sexes on one and the same branch. The plant has also another source of interest—it is poisonous to stock; the question has been much discussed, but we think the outcome decidedly shows that, under certain circumstances, the foliage and the seed are distinctly poisonous.

The gnarled stems and twisted branches of old specimens of Yew always attract attention, there is something weird and uncanny about them; but at the same time, a fascination which causes us to look and linger.

Tree lovers and botanists have paid much attention to the measurement of old Yews, and to the investigation of the rate of growth. DE CANDOLLE *primus*, many years since, and SIR ROBERT CHRISTISON of later years, devoted much patient research to these matters, and the reader desirous of obtaining a summary of the results obtained will find it in Dr. LOWE's attractive volume before us.*

The Yew is in one or other of its forms distributed throughout the northern hemisphere, barring the extreme north and the extreme south, so that it must grow on every variety of

soil, albeit in this country we generally associate it with limestone-soil, perhaps because other trees are more particular in their tastes. With such an antiquity, and such a distribution, it is no wonder that varieties have arisen, and some of these are so marked, and so confined to certain countries, that they are considered as distinct species by some botanists, and by most gardeners. It is, indeed, very much a case of individual judgment, and of varying standpoint, whether the botanist considers there is one Yew varying very greatly in different localities, or several species, each more or less confined to one country. Generally we see the Yew in the form of isolated specimens, but here and there we come across them forming an entire wood. The most extraordinary of these Yew-woods that we know of is the property of Mr. ABRAHAM DIXON, of Cherkley Court, Leatherhead. We reproduce an illustration of the Globose-headed Yew-tree at this place (see fig. , p.). It is difficult to exaggerate the variety of forms that may be found here, and the extraordinary interest they create. All these varied forms growing together can scarcely be considered as distinct species by the veriest "splitter." At the same time, they may be the germs of new species, which may, in the course of the ages, find themselves better adapted to certain conditions than others, and be preserved accordingly. Another remarkable Yew is that in Buckland Churchyard, Dover. It was of huge proportions, reft into two, one limb erect, the other nearly prostrate. Its age who shall tell? Now it is a symmetrical, bush-like tree, and it has changed its residence, and taken up its abode 100 yards or so from its old quarters. The history of its removal, illustrated with several cuts, was given in our columns in 1880. In some sense its removal was a triumph for the late Mr. BARRON. Eminent foresters, gardeners, botanists, archaeologists were consulted on the subject, and we believe the verdict was unanimously against removal, on the ground that it would be fatal to the tree. Nevertheless, BARRON was unshaken in his opinion to the contrary, and having had greater personal experience in transplanting monsters than any of his critics, his voice was listened to, his skill and enterprise were rewarded with success, and for a monument there is the tree in flourishing condition, less picturesque than before, for the prostrate branch was raised to its former position, but still more like what a Yew tree should be in an uninjured state, and apparently likely to go on for many more years.

Dr. LOWE, desirous perhaps of not occupying too much space, has devoted comparatively little attention to the varieties which are to be found in gardens. Of these the Irish Yew is one of the most remarkable, the branches all ascend, more or less, vertically, and form a columnar head. *Cephalotaxus pedunculata*, the *Podocarpus koraiensis*, or *Taxus japonica* of some gardens, affords a similar illustration. The value of the Irish Yew for certain forms of garden decoration cannot be denied. One of the largest of which we have a record is at Seaford, co. Down, which at the time of measurement a few years ago was 33 feet high and 58 feet round at 15 feet from the ground. The yellow-berried Yew is remarkable for the colour of its fruit. We were indebted to Viscount POWERSCOURT for some notice of the trees of this variety at Powerscourt.

The Dovaston Yew is a tree of great beauty, remarkable for the ends of its branches, which

are pendulous with elongated leaves. Its history is given in LEIGHTON's *Flora of Shropshire*. The original tree bore both male and female flowers, and from its seed seedlings were produced which reproduced the habit of the parent. As a great contrast there are the varieties called Foxi, *empetriformis* and *ericoides*, dwarf varieties suitable for the rock-work, with the leaves not twisted into two ranks as they are usually, but diverging on all sides as they do also in the Irish Yew before mentioned. *T. adpressa* is remarkable for its very short knife-like leaves. It is said to have originated as a sport from the common Yew, but that, though quite possible, is perhaps open to doubt.

The silver-variegated forms are less effective than the golden-leaved Yews, some of which are very brilliant, and confer a mass of colour that lightens up the dark of a shrubbery.

Dr. LOWE, of course, alludes to the curious fancy for clipping Yews into various shapes. This fancy has one advantage—it shows how well suited the Yew is to form sheltering hedges! Whilst we are impressed with the oddity of topiary-work, and admit that, in certain situations, and under special circumstances, it has a certain congruity with architectural features, it is, on the whole, not a practice which commends itself to the tree-lover. If already in existence in any garden, as at Levens, it would be vandalism to do away with it; but to start afresh with such freaks, is more consistent with caprice than with good taste.

THE ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral Meeting of the Royal Horticultural Society will be held on Tuesday, October 12, in the Drill Hall, James Street, Victoria Street, Westminster, 1 to 5 P.M. A lecture on "Some Curiosities of Orchid Breeding" will be given by Mr. C. C. HUBB, at 3 P.M.

MR. JOHN WEATHERS.—The announcement of the resignation of Mr. WEATHERS as Assistant-Secretary of the Royal Horticultural Society will be received with general regret. During the time he has been employed by the Society, and especially during the enforced absence of the Secretary, Mr. WEATHERS rendered valuable service. We hope shortly to hear of his appointment to another post, in which the experience he has gained at the Royal Horticultural Society will be of service.

DEVON AND EXETER GARDENERS' ASSOCIATION.—The annual business meeting was held in the Guildhall, Exeter, on the 30th ult., and the chair was taken by the president of the association, Mr. E. A. SANDERS, J.P. There was a large attendance, including His Worship, the MAYOR OF EXETER. The committee's report for the past year was read by the hon. sec., Mr. ANDREW HOPE, and proved to be generally satisfactory. The committee, however, finding that the small subscriptions paid by members, and the assistance from a few honorary subscribers do not permit of the funds of the association being used to provide prizes, recommended the discontinuance of the Hyacinth show, for a season at least. The report was adopted. The treasurer's report stated that the funds had been much reduced in augmenting the prize-list of the spring show, and that the balance in favour of the society was small. The membership, however, remained about ninety to one hundred. The president, hon. sec., hon. treasurer, and committee were re-elected. The first paper of the session will be read on the 13th inst. by Mr. J. MAYNE, Bickton Gardens, on "The Qualifications and Duties of a Gardener."

GLEICHENIAS FLOURISHING.—Few gardeners succeed perfectly in the cultivation of this beautiful genus of Ferns, and the result of this is, that from

* The Yew-Trees of Great Britain and Ireland, by John Lowe M.D. (London: Macmillan & Co.).

many gardens the species are practically abolished; or, if there be any, the specimens are poor ones. This is regrettable for several reasons, but principally because the species *G. rupestris*, *circinata*, *flabellata*, and others, when growing well, produce most elegant fronds, of a character eminently suited to various types of decoration, in vases or otherwise. We have recently been favoured with specimens of several species and varieties of this Fern from Mr. T. EASTWOOD, Lane House Nursery, Luddenden, which prove beyond doubt that at Luddenden they thrive wonderfully. Their cultivation at that place is de-

and every endeavour must be made to prevent sourness in the atmosphere and soil. In potting we use only peat and plenty of rough gritty sand. The pots are filled about one-third with drainage material. In summer we shade only slightly, and in a cool house when plentifully ventilated, very little is needed." The varieties sent by our correspondent are as follows: *G. dichotoma*, *G. flabellata*, *G. rupestris* var. *gigantea* and *glaucescens*, *G. dicarpa* and its variety *longipinnata*, and *G. circinata* var. *semi-vestita*, *Mendeli*, and *speluncæ*. The nomenclature of the genus has been very unsatisfactory, many

many fruits staged for that object. Thirty new members were elected, which makes a total membership of 213. The society has sustained a serious loss in the death of the Rev. J. Spittal, late Vicar of Haven Street, who was a honorary member from its commencement, and a very prominent horticulturist in the island.

THE DUNDEE CHRYSANTHEMUM SOCIETY is just now engaged in putting forth efforts to secure a record show this season. A circular inviting exhibits has been distributed to this end, and it is hoped that

FIG. 76.—THE CAULIFLOWER HEADED YEW AT CHERKELEY COURT, LEATHERHEAD. (SEE P. 252.)

scribed as most easy, for the accompanying letter states, "I have the plants by the hundred; they grow like weeds, and have done so for years. The marked frond (*G. flabellata*) has been grown in a cool house; for weeks in severe winter weather, the temperature of the house has been as low as 27° F., the soil in the pot having been frozen. The only injury is, as you see, that the growth of the previous year is seared and scarred, but in the spring each dormant bud on every frond and rhizome, puts forth growth as strong and beautiful as ever. The best winter temperature I find to be from 40° F. to 50° F. The house should contain an extremely wet, but sweet, atmosphere, and be always kept thoroughly ventilated. Constant root watering is essential both in summer and winter,

forms that are varieties only having been first published as distinct species. The consequent revision has produced an unusually long list of synonyms in a genus that contains so few correct species.

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.—At the monthly meeting of the above association held at Newport on the 2nd inst., Mr. S. HEATON read a paper on "Fruit Culture in the Isle of Wight." The exhibits were numerous and of excellent quality. Fruit was shown by Messrs. G. Bunyard & Co., Maidstone; T. Collister, Bembridge; C. H. Snook, Shanklin; and many local growers. The adjudication committee awarded several certificates for meritorious exhibits, and named

a liberal response will be accorded it. The show will be held on November 25, 26, and 27, and in addition to a London band, other instrumental and orchestral music has been arranged for.

GRAPE-JUICE AS INK.—There is a Vine known as the "Teinturier" that used to be cultivated at Chiswick, and probably is there now. The foliage is very ornamental, being bronze-red in colour, and the berries are small and deeply coloured. In a letter before us that was written by BARIO DE SOUTELLINHO, of Oporto, to Mr. CANNELL, of Swanley, attention is drawn to the fact that the juice of the Grape may be used as writing-ink; indeed the letter itself was written by just dipping the pen into one of these

Grapes. We have received some Grapes from the same source, and from the expressed juice which we have put into a small bottle, it is possible to write well enough. The Vine is very ornamental, and we should think easily procurable. The curious may like to try this. It is said that the Grapes of this particular Vine are used to colour wine which has lost its colour, or was obtained from light coloured Grapes.

ANNUAL OUTING.—The *employés* of Mr. W. COLCHESTER, Ipswich, manufacturer of "Ichthemio Guano," made their annual pleasure excursion on the 25th ult. The place chosen was Yarmouth, and a party of about sixty persons, which included a few visitors, spent a very enjoyable day.

PRESENTATION TO MR. G. A. BISHOP.—This well-known gardener, who was until lately in the service of Alderman S. T. MANDER, was recently the recipient of a testimonial from the Wolverhampton Horticultural Club, and friends in that town and district, as marking the estimation in which he is held, and in recognition of his services in placing the Chrysanthemum Society of that town in the high position it now holds. To Mr. BISHOP's endeavours the establishment of the Wolverhampton auxiliary branch of the Gardeners' Royal Benevolent Institution is likewise due. The testimonial took the form of an address and a gold watch.

WORM-EATING SLUGS.—Mr. WILFRED MARK WEBB, the Assistant Biologist to the Essex County Council, is continuing his researches on the distribution of these slugs in the British Islands, and especially that of *Testacella haliotidea*, the slug with the shell on his back. Those who come across specimens are requested to communicate with Mr. WEBB, at Ellerie, Brentwood, Essex.

ONION SHOW AT WISBECH.—In response to the offer of special prizes made by Mr. R. W. GREEN of Cornhill, Wisbech, his customers have just recently sent in their specimens of his "Prizetaker" Onion, and the show of bulbs was held on the 23rd ult. The result was as follows: 1st, Mr. J. BOWERMAN, gr., Hackwood Park, Basingstoke, with six bulbs, weighing 12 lb. 11½ oz., the heaviest specimen being 2 lb. 4½ oz.; 2nd, Mr. E. BROCKETT, gr., Aldenham House, with six bulbs weighing 9 lb. 8½ oz. There were many other fine specimens shown. It is Mr. GREEN's intention to offer prizes for Onions in 1898.

"YEAR-BOOK OF THE UNITED STATES DEPARTMENT OF AGRICULTURE."—This publication, dealing with the year 1896, has recently been issued from Washington, and furnishes us with a good idea of the patient and successful labour accomplished during that period. In addition to the report of the Secretary of Agriculture, which occupies some fifty pages, the volume includes papers by well-known specialists dealing with various agricultural matters. One of the most important treatises is by Mr. HERBERT J. WEBBER, on the "Influence of Environment in the Origination of Plant Varieties." The author treats his subject not merely from the standpoint of a scientific observer, but notes what may be called the practical side of the question, and how variation can be made use of and encouraged artificially, so as to adapt certain species for economic purposes. His paper is illustrated, and his observations are based and founded upon those of other botanical writers. Other articles in this year-book deal with such subjects as Potash and its function in Agriculture, H. W. WILEY; Common Poisonous Plants, V. K. CHESNUT; Timothy in the Prairie Region, T. A. WILLIAMS; Seed-production and Seed-saving, A. J. PIKE; Diseases of Shade and Ornamental Trees, Migration of Weeds, Improvement of our Native Fruits, &c.

SMITHSONIAN REPORT.—The Annual Report of the Board of Regents of the Smithsonian Institution (Washington) is now published, dated July, 1895. It is, as usual, a bulky tome, dealing partly with the progress and condition of the Institution, and with an Appendix composed of contributions from various

we may mention papers on "Air and Light," by Dr. HENRY DE VARIONY; "Botanical Work of the British Association," by W. T. THISELTON DYER; "Zoology since Darwin," by Professor LUDWIG V. GRAFF; "Race and Civilisation," by Professor W. M. FLINDERS PETRIE; "Centennial of the Institute of France," by JULES SIMON; and articles on HUXLEY and his Work, PASTEUR, and HELMHOLTZ.

HAMBURG EXHIBITION.

FRUIT AT HAMBURG.—The Königliche Ungarische Gartenbau Lehranstalt in Budapest furnished at the Hamburg Exhibition, a special tent to contain a selection of the best fruits from Hungary, ripe at the time of exhibition. I visited it on August 31, and saw some fine fruit of Pears Beurré Hardy, Souvenir du Congrès, Duchesse d'Angoulême, Beurré Superfin, Dr. Jules Guyot, Fondante des Bols, and Williams' Bon Chrétien.

Among the best Grapes I would mention: Chasselas Negropont, Portugais bleu, White Muscat, Chasselas, Tokay Angevine, and Madeleine Angevine.

Among the Apples were Empereur Alexander, and many local kinds not known in England.

The growers united in exhibiting the best varieties of early Apples, Pears, Peaches, and Plums. The best kinds of Apples are, for standards, a local variety; then Cardinal flammé, Gravenstein, Reine des Reinettes, Calville Rouge d'Automne, and Bellefleur Jaune.

One exhibitor, M. Julius Váárheley, showed a seedling of Bon Chrétien under the name of Marguerite Marillat; M. Karl Vidovazky, dessert Grapes, among them a variety with very long bunches called Augustaner; M. Julius Sigmond, Turkestan Melons; M. Josef Pisa, an interesting collection of water and sweet Melons, among them Frühe Prescott Cantaloupe, which succeeded out-of-doors.

The whole collection furnished a good example of the fruit culture of Hungary. The Exhibition, I hear, had a balance of more than 300,000 francs. This sum will be equally divided between the poor of Hamburg, and the Société d'Horticulture de Hamburg-Altona, which proposes to construct some permanent premises for horticultural purposes.

THE SPECIAL FRUIT SHOW, SEPTEMBER 17—30.

This was the last of the temporary shows held during the progress of the Hamburg Horticultural Exhibition. The 12,000 square metres of glazed or roofed buildings occupied by this large and successful undertaking, as well as two large tents rendered necessary for the autumn show, were filled with fruits of all kinds. Of course, Apples and Pears were in the majority, and there were many exhibits of Grapes, but Plums, Peaches, Greengages, Tomatos, Elderberries, Strawberries, Medlars, Melons, Pineapples, Nuts of various kinds, Almonds, dried Plums, Chestnuts, and Quinces were largely represented. Open-air fruit, as well as that ripened against walls was very fine.

Every part of Germany was well represented. This may partly be explained by the fact that last year 500,000 barrels of Apples were imported to Hamburg from the United States, boding complete ruin to the German fruit-trade. The Government therefore desired all the States and Societies to take a large part in the present congress, an appeal to which all responded.

Besides Germany, the following nations were represented at Hamburg: Sweden, Norway (a fine exhibit), Switzerland, Holland, interesting contributions; Denmark, Tyrol, very fine; Spain, Hungary, very remarkable; and France, more wonderful in quality than in quantity. As these exhibits came from north, central, and southern countries of Europe, and from different quarters of these countries, the influence of soil, climate, &c., could be noted, and suggested most interested and profitable subjects for study.

The various methods of staging were also noteworthy. Most exhibitors used dishes of various kinds, supplied by the committee to the number of 50,000. Others used willow-baskets, large and small, round,

and rectangular; or wooden-cases, in which the exhibits were packed as for transit; or barrels of various sizes—all carefully arranged.

I would mention among the exhibits the Vines and Apples grown in pots.

Among the most conspicuous exhibits, judging from a hasty survey, I would include those from Holland, Schleswig-Holstein, Tyrol, Mecklenburg, and France. This latter country had an exhibit of some excellent fruit: Apples, such as Belle Dubois, Belle fleur jaune, Gros Api, Empereur Alexandre, Calville blanc; Pears Baurré d'Arenberg, Beurré Superfin, Doyenné d'Hiver, Beurré Diel and Pesse Crasane; Peaches of great beauty, coming with other fruit, from Montreuil. I would add that it was the Société régionale d'Horticulture de Montreuil sous-Bois that organised this fine exhibit.

Among Pot Vines shown by MM. Götsch and Hamkens, I would call attention to Trentham Black, Gros Colman, Rother Guteidel, Weisser Guteidel, Alnwick Seedling and Lady Downe's Seedling.

Hungary, which had, as stated at the end of August, sent a fine contingent of fruit, occupied on this occasion an entire tent with exhibits. I must also allude to M. Winter, of Bordighera, who most artistically arranged some fine fruits of Palms; and large and fine Crotons. The fruits were those of Citrus sinensis nana, Bigarade, Pomum Adami, C. decumana, C. Limonium, and Opuntia. I must not forget the fine Grapes from M. Etienne Salmon, of Thomery (France), including a hundred choice varieties. It was the unanimous opinion of the jury that the fruit show was the finest and most complete ever held.

ENGLISH GRAPES.

I observed the splendid Grapes from Mr. John R. Hamilton, Waltham Cross—surely the finest in the exhibition. I noticed Gros Colman, Cannon Hall, Alicante, Muscat of Alexandria, Black Alicante, Gros Marco, Mrs. Pines Black Muscat, and Black Hamburg; all these varieties were represented by enormous bunches of very large fruit, well coloured. Ch. De Bouschère.

BELGIUM.

ANTWERP.

In the houses of the well-known Antwerp horticulturist, M. Florent Pauwels, there were, in the middle of September, many Orchids in bloom, among them *Saccolabium retusum*, with a large and very pretty raceme; a species of *Coelia*, with rose-claret flowers, which might well be *C. macrostachya*; *Miltonia virginalis* and *M. Clowesi*; *Dendrobium formosum* giganteum of great size, with a splendid pure white lip widely striped with yellow, shading into deep orange-yellow at the base; *Zygopetalum Gautieri*, a magnificent variety; *Oncidium St. Legerianum*, flowering for the second time on the same branch; *Odontoglossum biconense* album, with a beautiful white lip; *O. polyanthum*, well marked; *Phai-nopsis E. neralda* and *coronavi*; many fine *Cattleya* *gigas*; *Oncidium Papilio*, with a large and splendid lip; *Catasetum Bungei*; *Laelia Pinelli*, very dark; *Cypripedium Morganii*, in bloom since the end of July; *C. Dominyanum*; *Pauwelsii*, which I have found in flower on each of my visits; *auricularium*, with a pretty green standard; many plants of *Charlesworthii*, and of *Odontoglossum Rozii* album.

The rosery of M. Pauwels surprised me by the vigour of the plants included in it, and by the number of these covered with bloom, for instance William Allen Richardson, Captain Christy, Gloire de Dijon, Céline Forestier, Madame Hoste, La France, Dr. Grill, Abondance, and Fürst Bismarck. Among novelties coming from the firm of Souper & Notting, of Luxembourg, I would name Madame Jean André and Antoine Rivière.

In the houses of M. GUILL. DE BOSCHERE I noted a very pretty variety of *Odontoglossum*, *album*, with the divisions of the

hue; and a very wide, milk-white lip; a variety *cidium luridum*, quite distinct from the type, the corolla a beautiful reddish-brown colour, the lip of fawn with two wine-red tubercles, the lateral lobes instead of white as with the type were yellow speckled with red, and the wings of the column rose-coloured. The petals are rosy-red marbled with white in the middle, the other half is reddish-brown bordered with white. The whole appearance of the flower is charming, and the variety is named *O. b. superbum*. *Ch. D. B.*

KEW NOTES.

ANTHORRHOEA QUADRANGULATA.—A fine example of this, the best known species of the Australian *Boys or Grass Gun Trees*, is now in flower in the Succulent-house at Kew. It has a stem 6 feet long and 9 inches in diameter, bearing a head of green rash-like leaves a yard through, and an

Governor of Fiji, in which island it is indigenous. The plant possesses the habit of *M. sapientum*, having leaves of a glaucous green colour, and an inflorescence remarkable for its large size, and the rich red-purple colour of its bracts. The same plant flowered at Kew, two years ago; but failed then to ripen seeds. The fruit is said to be six inches long, yellow when ripe, not very palatable in the raw state, but excellent when cooked. The plant is common in the forests of Tahiti, and the fruits are largely consumed by the Tahitians. In the low lands the fruits are seedless, but occasionally they are fertile at an altitude of 3,000 feet. It grows freely in a stove, and is worth including among the ornamental species of Musa.

PITCAIRNIA FERRUGINEA.

This is one of the few Bromeliads which may be grown in the temperature of an ordinary greenhouse, and it is handsome enough to merit a place in any

FIG. 77.—MASDEVALLIA PACHYURA: FLOWERS WITH BARS AND SPOTS OF RED ON A GREEN GROUND.

spike 6 feet long, which in form is similar to pike of *Typha latifolia* (Bulrush), the stalk measuring 4 feet in length, and over an inch in diameter, whilst the head is 2 feet long, and 2 inches thick, of a black-green colour, the lower portion being covered with small white star-like flowers. The same plant flowered at Kew three years ago. It is a native of South Australia, where it inhabits rocky hill ranges. Several species of *Xanthorrhoea* are cultivated at Kew, but they all thrive in a warm greenhouse if planted in sandy soil, and kept fairly moist all the year round. Anything approaching dry treatment is injurious or fatal to them.

MUSA FEH.

This interesting species is again in flower in the Succulent-house at Kew. It is supposed to be identical with *M. Seemannii*, of which a figure was published in the *Gardeners' Chronicle*, 1890 (ii), p. 182, from a photograph sent by the late Sir John Thurston,

large conservatory. In the Temperate-house is a plant of it with a dozen heads, forming a mass 8 feet high, and as much in diameter. Its leaves are more than 1 yard long, whitish, with large, marginal, brown spines, and flower-spikes 6 feet in length. The flowers are long and loose, the calyx covered with a rusty tomentum, and the petals of a yellowish-white. It is the *Puya grandiflora* of the *Botanical Magazine*, t. 5234. According to Mr. Baker, it sometimes attains a height of 12 feet.

SOLANDRA GRANDIFLORA.

The large plant of this vigorous tropical climber is again flowering freely in the Succulent-house, where the dryish atmosphere and liberal allowance of bright sunshine (the house is never shaded) are conducive to strong growth, handsome foliage, and a plentiful crop of large, trumpet-shaped, yellowish-white flowers. In the moister conditions of the Palm-house it grows freely, but does not flower. *W. W.*

MASDEVALLIA PACHYURA.

THIS rare species was first briefly noticed by the late Professor Reichenbach in the *Gardeners' Chronicle* 1874, Vol. ii., p. 322 (see also 1881, Vol. ii., p. 336). The flowers are of a green colour, horizontally barred with red. We extract the following particulars from Miss Woolward's excellent monograph of the genus:—

"*Masdevallia pachyura* was discovered by Roehl in the mountains of Ecuador, and was first described by Reichenbach in 1874 from dried specimens. The plant represented in the illustration (fig. 77) was recently imported by Consul Lehmann for Mr. James O'Brien, to whose kindness I am indebted for the opportunity of drawing the first flowers of this species ever seen in cultivation.

"Consul Lehmann sends me the following note:—'*M. pachyura* has a comparatively small distribution along the western slopes of the Western Andes of Ecuador, from the mountains of Zaruma in 3° 30' S. latitude, to the western slopes of Chimborazo in 1° S. latitude, at an elevation of 1700 to 2300 mètres (5525 to 7475 feet). It is abundant in one small district only, viz., around Cayandelet, on the road from Puente de Chimbo to Sibambe, and above Pallatanga on the road from Puente de Chimbo to Cajabamba. In all other localities it is very rare. It usually grows on trees in very damp thick woods, but occasionally I have found it growing upon walls of rock, as at Gualashay, on the road to Guaranda. It flowers in March and April, and sometimes also in November. The mean temperature of its habitat ranges from 15° to 18° Centigrade (59° to 64° Fahr.).'"

The illustration was obligingly forwarded by Miss Woolward.

HOME CORRESPONDENCE.

A TWO-FACED DAHLIA.—Calling at Dr. Patterson's, The Bridge of Allan, on Saturday, 2nd inst., I found the venerable Doctor in his study—his school, as he characteristically called it, deeply absorbed in many interesting objects, living and dead. One of those which seemed to interest him much was the most perfect two-faced Dahlia I had ever seen. The variety was much like one that I knew many years ago as Donald Beatson, and would have formed a sparkling article for the *Cottage Gardener* had the Dr. met with it, say, forty years ago. The two faces were about alike perfect. There was no back, and the stem came down the middle between the two faces. Attempts at such monstrosities are by no means unknown among Dahlias, and I have met with some attempts to look straight to all the cardinal points of the compass. But I agree with the venerable and gifted Doctor, whom it was a great pleasure to meet, that this was the most perfect two-faced Dahlia yet seen. Dr. Patterson's host of friends, North and South, will be pleased to hear that his interest in nature, art, and antiquities is as lively, absorbing, and as satisfying as ever. *D. T. F.*

THE CLIFTON ZOOLOGICAL GARDENS, BRISTOL.

—These charming grounds and gardens, which are under the management of Mr. G. Harris, well repay a visit. During September the flower-beds were very gay with tree and shrub in glorious leafage, scarcely a tint of autumn being perceptible on this elevated spot. One great object of interest to gardeners is the long border of hardy Ferns, on which can be seen many varying abnormal forms of *Scolopendrium*, with elegant and graceful, as well as robust forms of other genera. On the cool, alady border which runs for a considerable distance, these Ferns thrive considerably, being doubtless helped by a good top-dressing of leaf-soil afforded in the spring. Mr. Harris has been successful in raising seedling *Fuchsia*, and can point with pride to several new varieties of more than ordinary merit two of which have received names, viz., Dr. Shaw, a fine and striking variety, of fine form, the tube and sepals bluish, the latter with a pink reverse; the corolla pale purple, with a carmine beading on the surface; the other, which partakes a great deal of the Mrs. Russell character, has been named Thomas Hobbs; the tube and sepals are of a sort of orange-carmine, with slightly green-hued tips; the corolla is of carmine, flushed with purple, and irregular in shape. This plant is made a leading feature in these gardens. The plants are admirably kept, and the devoted florists alike can find much to inter-

FRUIT WALLS.—Much of our choicest fruit comes from wall-trees, and in numerous gardens in all parts of the country the management of the trees is well understood, and the work is well done. In others, we find only neglected trees, with the inevitable result—indifferent fruits of all kinds. I have in my mind's eye some walls in an old kitchen-garden in the "Garden of England." These walls are partially covered only with snaggy, worn-out trees that seldom bear a fruit fit to be put on the table, which have never been lifted or transplanted, nor any attempt made to put the border into a suitable condition for growing healthy trees and fine fruit. Walls we find absolutely indispensable for the perfect culture of the trees, but the border is dug every year once or twice up to the stems. It is true the building of good walls costs a large sum of money, but when built they are good for a century or two, and if they are planted with a choice assortment of fruit-trees of all kinds, they have a pleasing appearance, besides affording, with proper attention, abundant crops of fine fruits. Of course, garden-walls cannot be allowed to go for a great number of years without attention in the matter of pointing the courses, and filling up nail-holes, mending wires if they are wired, and seeing that the coping is kept in condition so that moisture cannot penetrate the masonry or brickwork. It is poor economy to build your wall and then neglect to keep it in repair. Such a neglected, ill-conditioned wall is that which was found alongside the ill-managed border and snaggy trees. And the selection of sorts and varieties matched the wall and border in regard to quality, lack of appearance, and every point that makes fruit appetising and desirable as food, or an adjunct to the table. *H. Markham, Margate.*

EARWIGS AND PEACHES.—I have been struck this season by the singular fact that while the Nectarines on a wooden fence have been severely injured by those plagues of the gardener, the earwigs, the Peaches have nearly escaped. Hundreds and thousands of these and other insect pests have immolated themselves in bottles of syrup secured to the trees, and as many have been trapped by the hollow stalks so commonly employed. I have never seen any reference to the comparative immunity from molestation that the Peach appears to enjoy, and should be glad to learn if any of your correspondents can confirm my experience. *W. T., Ipswich.*

ARAUCARIA IMBRICATA AND GOLDEN-LEAVED HOLLIES.—Probably an unique example of effective results obtained by planting two kinds of ornamental trees close together can be seen in the new cemetery at Bournemouth. The avenue which leads from the entrance-gate to the chapel is planted with alternately a pyramidal Golden Queen Holly and *Araucaria imbricata*. The contrast between the dark green of the one, and the yellow variegation of the other, is extremely effective. The trees are growing luxuriantly. There may be two opinions as to the general suitability of such an arrangement, but there cannot, I imagine, be any doubt of its suitability in the cemetery. The *Araucarias* measure 15 to 20 feet in height, and show that divergence in form so characteristic of these noble trees when raised from seed. The idea of planting *Araucarias* and golden-leaved Hollies alternately is, I believe, due to Mr. Cutler, a prominent citizen of Bournemouth. It is easy to criticise, and I would venture to make the suggestion that bushes of the golden-leaved Holly would have been more appropriate than pyramids, as being also very effective in years to come, when the branches had reached the ground all around them. Few persons are aware of the wonderful vigour of this variety in suitable soil, as is the case in this instance. It may be said by some that in the course of time the *Araucarias*, notwithstanding the delightful way they clothe the ground around in early life, may themselves become bare at the bottom and flat-headed, and thus destroy the contrast between them. *William Earley.*

LARGE PEACHES.—In your issue of the 18th ult., I read an interesting communication from J. Parkin, Blaitwaite, Carlisle, upon the subject of his production of Barrington Peaches of a large size. We also have had immense-sized Barringtons this year. The tree is several years old, and produced this year 118 fruits, the largest of which weighed 15½ oz. Six of the largest weighed 5 lb. 6 oz., an average of over 14 oz. each. The average weight of the crop was fully 10½ oz. each. The quality was also excellent in flavour. *Joseph Broome, Sunny Hill, Llandudno.*

A DWARF SWEET PEA.—I have a seedling Sweet Pea whose height, when fully grown, is about 2½ feet.

This variety was raised by fertilising some blooms of Cupid with the pollen of Emily Henderson. Its flowers, of a pure white, are produced most abundantly from the bottom to the top of the plants. The individual blooms are quite as large and the peduncles as long as in the pollen parent, so that it will be as useful for cutting as the taller-growing Sweet Peas; while its advantages in other ways over these varieties are many, inasmuch as it may be planted in flower-beds and borders where the tall ones would be unsuitable. In the present style of mixed bedding it should be useful, as white-flowering plants of this height, and suitable for bedding, are few. I have no doubt that in the course of a few years we shall have dwarf varieties of Sweet Peas in other colours. *H.*

ARAUCARIA IN NORWAY.—I send you an account of the largest *Araucaria imbricata* in Norway. The tree stands on the ground of Balestrands Parsonage, 61° 15' N. lat., in the west part of the country. It was introduced from England in 1873, and was then 0·31 metres high. On December 5, 1896, it had attained a height of 7·715 metres (about 24 feet), and the stem measured at 0·30 metres above the soil, 0·82 metres in girth. The tree has not been protected since 1876. Flowers in 1896 showed it to be a male-tree. *Peter Nøvik, Editor, Secretary of the Norwegian Horticultural Society.* [The illustration shows a well-grown tree. *Ed.*]

DO ORCHIDS DEGENERATE?—A good example in support of the argument that Orchids do not degenerate under cultivation more than other plants, is to be seen in the *Phalaenopsis*-house in Lord Rothschild's garden at Tring, where some of the species have attained to great size and vigour. Many of the largest specimens have occupied the same warm central division of a range of rather low houses, which are sunk a little below the ground-level, for upwards of twenty years. Occasionally after very long, trying winters, or after very exceptionally hot summers, Mr. E. Hill, his lordship's gardener, has observed that some of the plants lose their leaves, and are apparently not in such good condition as usual, and for a few weeks there is some anxiety felt regarding them. The plants invariably yield, however, to the influence of better weather, no attempt being made to bring about a change in the affected plants by other than the ordinary methods. Sometimes during the critical period, a plant will decline, and become a very poor specimen; but generally, the plant will take a turn for the better, and in two or three years it will regain its usual vigour and size. Many fine specimens of *Phalaenopsis*: *Aphrodite*, *P. amabilis*, and *P. Schilleriana* have been in the collection for more than twenty years; the Tring Park specimen of *P. intermedia*, which flowers so magnificently, and is noted in Veitch's *Manual of Orchidaceous Plants*, as the finest specimen in cultivation, has been in England even much longer than that; the largest *P. Stuartiana*, which has now several young plants sent forth from its roots, was one of the first plants imported in 1881; and most of the others, including species as well as hybrids, consist of the earliest which could be procured. And yet the *Phalaenopsis* are considered by many to be impossible to keep in good condition for any length of time, and some cultivators even fall altogether with them. The fact seems to be that unless a house can be found to suit them, it is useless to attempt their culture; but once such a house is found, they should on no account be shifted to another. The suitable house at Tring Park and in some other places is a comparatively small, lean-to, or three-quarter span, which can be kept at a regular temperature of 65° to 75° Fahr., and which is a middle one of a range, and consequently has not a door that opens into the outer air. *J. O.B.*

LOOK TO YOUR CHRYSANTHEMUMS!—A short time since we received some leaves of *Chrysanthemum* under cultivation, which were diseased, and threatened with destruction. These leaves were examined, and exhibited on the under-surface unmistakable proof that they were attacked by some "rust," not unlike in appearance to that which infests Thistles. Microscopical examination proved that the fungus-disease was caused by a "rust" or species of *Uredo*, probably only the *Uredospores* of some kind of *Puccinia*, in which the teleutospores, or final spores, are bicellular, and not one-celled as in the *Uredo*. This particular species appears to correspond with *Uredo Hieracii*, but this cannot be affirmed until the teleutospores are found. During the past week we have received *Chrysanthemum* leaves from two or three correspondents, affected

with the same disease in a more aggravated form; but still no teleutospores have as yet been found. The leaves are spotted on the under-surface with powdery rust-brown spots, or pustules, which break through the cuticle, and consequently are endophytic, or developed outwards from within the tissues. In some cases the pustules grow so close together that one half of the leaf seems to be covered with a bright rusty-looking powder, which is made up of myriads of elliptical spores. These, when mature, are quite powdery, and are easily dispersed in all directions. Under favourable conditions, these spores are capable of germinating, and the germ-tube then produced may enter a healthy leaf by means of the stomata, and, having established itself, spread the disease indefinitely. Thus having once become infected, there is little hope of saving the plants from destruction, unless, when it first appears, it is possible to pick off all the diseased leaves and burn them. The application of sulphur in this instance is useless, as it is inapplicable in this class of disease. The use of one of the copper solutions would probably be beneficial in preventing the spread of the pest, but it would not recover the leaves when once infected. It has been recommended in similar affections to syringe the leaves with Condy's Fluid, but in doing this the under surface of the leaves must be well sprinkled. As far as we are aware, this is the first year in which *Chrysanthemums* have been attacked by this parasite, which is, nevertheless, not uncommon on other composite plants. In all the instances which have come under our notice the infection has been most complete, and the production of spores profuse. We should recommend careful watching, and the syringing of all plants surrounding those attacked with some fungicide which would destroy the fugitive spores, or prevent their germination; but after the plants are once attacked by this kind of pest, it is almost hopeless to make any impression upon them by spraying, which will only be useful in checking the spread of the disease. *M. C. C.*

NYMPHÆAS.—I should like to say a word in favour of these beautiful and interesting plants, which deserve to be more extensively cultivated than is the case at the present time. In summers like the one we have been having, it is astonishing how very freely they flower, and how very beautiful are the flowers. My employer, having a great liking for aquatic plants, I have these last three or four years been able to grow a good many species, and should be glad to speak well of them. We have a goodsized pond with a constant spring of water rising in it, and with the over-flow from this pond I have made several others, about the size of large flower-beds, varying in depths of water from 6 inches to 2 feet. In the shallow water, which of course is round the edges, we place such plants as *Nymphaea pygmaea*, *Nymphaea pygmaea helvola*, *Nymphaea odorata minor*, *Villarsia Humboldtiana*, *V. reniformis*, *Limnorchis Humboldtiana*, *Alisma natans*, these make a very pretty edging to the large *Nymphaeas*, which are planted in the deeper water towards the centre of the ponds. I find 18 inches of water with plenty of mud suits most of the large *Nymphaeas* best. When the water is deeper than that they do not grow so well. The *Nymphaeas* are planted in water varying in depth from 1 foot to 2 feet, according to their habit of growth, the stronger-growing varieties in the deeper water. I will pass a few remarks on the ones we have grown here, and which have done well, viz.: *Nymphaea gigantea*, is a very strong grower with a large pure white flower standing well above the water, and remaining open till late in the day. [The true *gigantea* has blue flowers. *Ed.*] *N. caroliniana* is a strong grower, flower large, of a delicate rosy-pink. *N. candida* is another robust grower, flowers white, very large, free flowering, and very hardy. *N. Marliacea alba*, a very fine Water Lily that everyone should grow; flowers white, pink-tinted. *Nymphaea tuberosa* and *N. plenissima alba* are two free-flowering white varieties. *N. Marliacea carnea* is a very lovely flower, large in size, of a delicate flesh colour, wonderfully free in flowering, and of a robust habit. *N. odorata rosea* is a charming rose-coloured flower; free flowering, and of moderate growth. *N. o. exqu Coast* has rose-coloured flowers, rather darker than those of *N. o. rosea*, much the same in growth, but not quite so hardy. *N. o. sulphurea* has large flowers, which rise well above the water, the colour being sulphur-yellow; the foliage is beautifully marbled, and the plant of a robust habit—one cannot speak too highly of it. *N. o. s. grandiflora* is similar to the last named, and same in all respects, except

that the flowers are larger and a shade lighter in colour. *N. Marliacea chromatella* has a grand creamy-white flower, the foliage very robust and marbled; the plant is hardy and wonderfully free-flowering. *N. Laydeckeri rosea* has bright rose-coloured flowers that shade off into almost purple as the flower ages; the foliage is marbled, and of medium growth. *Nymphæa Laydeckeri purpurata* has deep purple-coloured flowers; and *N. L. lilacea* has, as its name implies, lilac flowers. The last three have much the same kind of habit of growth, and they are free-flowering. *N. flava* has small, prettily mottled leaves, and flowers of a canary-yellow colour, but it is not free-flowering. *N. cyanea* has done very well with us this summer, but I cannot recommend it for planting in out-door ponds; and only that we so greatly wanted a blue-flowered *Nymphæa* amongst the hardy ones, it would not have been planted. It is planted in an Orchid-pan, so that I am able to remove it to warmer quarters in the winter; it is put into the pond about the middle of June. *W. J. Townsend, Sandhurst Lodge, Wokingham.*

DO PIGEONS EAT SLUGS?—I have recently been told that pigeons feed abundantly on the small slug. I have never looked on them as brother gardeners, but if the information is true, I would gladly welcome them as such. But is it true? *H. N. Ellacombe, Bilton Vicarage, Gloucestershire.*

NEW INVENTION.

I SEND you herewith a sample of my new "Ideal" label and holder (patented). The following are the advantages I claim for it:—It is the cheapest as well as the neatest label (fig. 78) on the market; and it has this great advantage, that the label can be taken off the stem to be written upon. The stem may be used any number of times for different labels. The label can be used on both sides, thus saving 50 per cent. in labels alone. It cannot face the wrong plant, as single-stem labels are apt to do. Mr. John Pinches, of Camberwell, is manufacturing it. The cast Acme label can be made to fit the holder; and I am supplying a stouter zinc label with my name stamped in at 3s. 6d. per dozen, complete. *E. H. Harry, 36, Adelaide Road, Brockley, S.E., Sept. 29, 1897.*

NURSERY NOTES.

ANOTHER KENTISH SEED FARM.

SOME four years ago, that famous Scotch seed-firm, Messrs. Dobbie & Sons, who had previously a farm so remote as Beaulieu in the New Forest, resolved to get nearer London, and they therefore secured the lease of a fine open space of ground at Orpington in Kent, near the railway station, and right under the shelter of the lofty South Eastern railway embankment. The position is very open, and it is also on a slope or hill-side, affording a maximum of sunlight and air. The soil is of the ordinary loamy brash on chalk. On a seed-farm, the range of plants cultivated is remarkable; and few places to the flower-lover or general gardener are of more interest. There is also so much of interest in noting methods of growing for seed-production, the extreme care shown in keeping the various stocks select and true, and of not generating too luxuriant growth, lest the object in view be discounted.

Messrs. Dobbie & Sons have a high reputation for African and French striped Marigolds. The strains are, as seen growing, undoubtedly of the very finest. Of the Africans, the orange-and-lemon forms have flowers as big rounded, massive, and of their kind as perfect as the world produces. They are indeed marvellous Composites, and it is interesting to compare them to the singles growing beside them. When I was in the business and growing Marigolds, I invariably pulled out every single from the stocks, and always got plenty of good seed. Mr. Fyfe, the Orpington member of the firm, holds differently, for he regards the single flowers as indispensable to furnish pollen for the doubles. I noticed that there were no intermediate flowers anywhere, every one was either a high class double or a real single. Each colour is

separately grown. There is an immense breadth of the tall striped strain of French Marigolds; none in form of flower or of markings could be more perfect. I have never seen better striped French growing in bulk. Of the dwarf or compact section there is of self, orange, lemon, and chestnut-red, all perfect in flower and colour; there is also a dwarf striped strain, and that and the orange seem to be the most in demand. The plants are about 10 inches in height, blooming profusely, the flowers being of the finest form.

Asters are great features at Orpington. The plants were less strong than usual owing to the drought. Long beds of all conceivable colours followed one after the other, and of all the leading sections *Pæony-flowered*, *Victoria*, *Mignon*, *Comet*, *Princess* and *Quilled*. Of the latter alone there are twenty-eight diverse varieties. Nearly all the Asters grown here are of several years' home-growing, and the quality in every case remains of the highest. Inter-crossing with these flowers is rare even when grown side by side. Two new ones have come from seed, and one plant only of each. One a quilled variety of two diverse rings of blue with a white centre, and the other a flat-petalled *Victoria* of a pleasing and distinct *Heliotrope* colour.

FIG. 78.—"IDEAL" LABEL AND HOLDER.

Dahlias of every description, from the finest Show to the quaint single Cactuses, are grown to produce seed and roots, which are all later sent to Rotham for propagation. In the firm's northern home, as many as 16,000 of these diverse Dahlias are grown—really a wonderful number.

Good strains of double Hollyhocks are here for seed, and big breadths of *Violas* from winter-established plants in big clumps seed profusely. All the best-known varieties of good robust habit are here. Very beautiful are the *Pentstemons*, some of the new or continental varieties grown in quantity have not only very fine flowers, of which the pencilled throats are the best, but in bulk show remarkable fitness for bedding. Such varieties as *Emilie Deschanel*, deep carmine-red; *Alphonse Daudet*, magenta; *Emilie Paladilhe*, beetroot-red; *Claude Gellée*, intense red; *Mrs. Laidlaw*, rosy-pink; and *Dietz-Monnim*, deep violet, are splendid, and these will give fine seed crops, with many others. *Antirrhinums* are very varied and fine. Special attention is devoted to securing fine selfs for bedding, yet having large flowers. A pure white, a yellow, and a rich crimson are first-rate for this purpose. The pot Marigolds *Orange King* and *Meteor*, in large breadths, make a fine show. Sweet Peas have been harvested, and the new pink-flowered dwarf variety

Cupid is found to do better than the white variety. Of great interest and beauty is *Michauxia campanuloides*, which sends up branching stems 6 feet in height from plants raised last year, and which have stood the winter outdoors. The habit resembles that of a robust *Chicory* plant; the flowers are pure white, have eight narrow petals, and bear superficial resemblance to those of *Passiflora*. The seed-pods resemble those of the *Canterbury Bell*; the foliage is elongated, and is somewhat of the *Acanthus* character. A patch of single striped Dwarf French Marigold shows this plant to be even prettier than is the popular *Legion of Honour*.

Naturally the firm grows vegetable seeds very largely also, and foremost amongst these are Onions. Large breadths of bulbs are growing to produce stock, and these will be planted next year in big breadths to produce seed. The firm are less concerned to have many diverse names for Onions, than to secure the best possible type of oval or globe, round and flat, to suit customers' special requirements. It is obvious that Onions bear to each other remarkable likeness, though shape, or colour, is the chief distinguishing feature. Large breadths of *Tomatos* in the open have done well. There is here a very beautiful—indeed, perfect—strain of decorative *Parley*; and the *Victoria Kale*, a splendid advance in all respects on the tall curled Scotch, is in its best form. The *Leek* is largely grown and plants in quantity in the seedling-stage, as also *Carrots* of all the best stocks were observed. *Paranips*, *Beets*, &c., and *Turnips*, especially *Golden Ball*, recently sown in drills, will furnish numerous bulbs for seedling next year. It is in this way so imperfectly described, that our home seed-firms labour so conscientiously to produce at home for the British public the finest of seed stocks. *A. D.*

SOCIETIES.

ROYAL HORTICULTURAL.

SEPTEMBER 20 AND OCTOBER 1, 2.—A full report of the competitive classes at the Crystal Palace Fruit Show held as we were passing through the Press, was given in our last issue. We now append a few notes upon the non-competitive collections of fruit and flowers staged on the same occasion, many of which were grand examples of nursery produce.

Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley, made an exhibit of some size, which included a fine lot of Apples and Pears, and in the centre were a few *Malden* Apple-trees bearing very good crops of fruit. Prominence amongst Apples in this exhibit was given to *Bismarck*, a variety that does exceedingly well in these nurseries; *Prince Albert*, *Bess Pool*, *Ribeton Pippin*, *King of the Pippins*, *Lord Derby*, a good cooker; *Cox's Orange Pippin* (very fine fruits from bushes 4 feet over); *Jubilee*, a late bloomer, and a valuable sort; *Warner's King*, and *Dumelow's Seedling*. *Cowan's Victoria* is a pretty little Apple of some merit for dessert, but it has never made its way though raised about fifteen years since. Of *Pears Duchesse d'Angoulême*, *Pitmaston Duchess*, and *General Todleben* were represented by some first-rate specimens, a fruit of the last-named weighing 2½ oz. *Burré Nigan* and *Burré Goublat* were also noticed among the others in the collection.

From the Handsworth Nurseries, Sheffield, Messrs. FISHER, SOX & SIBRAV, exhibited a collection of Apples and Pears in about eighty-five varieties, that though less good in appearance than others from the south, were capital for that district. *Tower of Glamis* and a few other good sorts for planting in the Midland and Northern Counties were shown, also a few excellently-trained trees from the open of Apples and Plums, of which the firm possess a very large stock.

The Horticultural College, Swanley, was represented by an exhibit of Apples and Pears, Nuts, Melons, and some good black *Alfonse Grapes*, as also a number of bottles of preserved fruits.

Messrs. PEED & SONS, Roupell Park Nurseries, West Norwood, made an exhibit of fruits, composed for the greater part of Apples and Pears, but inclusive also of a few choice Grapes. Many of the Apples and Pears were represented by first-class specimens, and the following were put up in baskets that held a considerable number of fruits, *Brunswick*, *Golden Pine Pippin*, *Blenheim Orange*, *Cox's Orange Pippin*, *Emperor Alexander*, &c.; and Pears, *Marie Louise*, *Burré Diel*, *Pitmaston Duchess*, *Durondeau*, &c.

One of the tables was laden with fruit from HER MAJESTY'S Gardens at Frogmore (gr., Mr. O. Thomas). It contained fine Grapes, first class heavy *Pine-apples*, a representative display of Apples and Pears of good quality, and an abundance of *Tomatos*; indeed, the most prominent feature of the exhibit, and the most attractive

of the variety Golden Jubilee, an excellent, yellow-skinned Tomato raised at Frogmore. There were Grapes of the following varieties: Muscat of Alexandria, Lady Downes Seedling, Raisin de Calabre, and Black Alicante. There were several Melons; and the Pines, of which there were upwards of a dozen, were splendid.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, Chelsea, London, S.W., exhibited an uncommonly representative collection of Apples and Pears—Apples, on the whole, being those best shown. Including Apples and Pears there were something like 170 dishes. The arrangement of the baskets and dishes of fruits, unrelieved in any way, was in our view hardly so pleasing as it might have been. Some of the best shown Apples were put in baskets running along the centre from end to end of the table. In these were such varieties as Gloria Mundi, Tyler's Kernel, Warner's King, Blenheim Orange, Loddington Seedling, Norfolk Beautif, Stirling Castle, Laue's Prince Albert, Cox's Pomona, Alfriston, Sandringham, Winter Hawthornden, Lady Henniker, Red Hollandbury, Lord Derby, Seaton House, Bismarck, King of the Pippins, Peasgood's Nonsuch, Ribston Pippin, and Cox's Orange Pippin, the two last-named being particularly good. The Pears of such varieties as Beurré Fonqueray, Marie Louise, Doyenné du Comice, and Pitnaston Duchesse were the best.

An exhibit from Messrs. SUTTON & SONS, Reading, consisted exclusively of Tomatoes. They had heaps of fruits, representing six or seven varieties, that constitute the specialties of the firm in regard to this fruit. Sutton's Peachblow is of the type possessing an appearance similar to that of a Peach, and is described as being better than other such varieties, which we have generally found to be rather wanting in flavour. Sutton's Al and Sutton's Perfection are both good Tomatoes, the latter being the best for most purposes. The fruits are of the true Perfection type, solid, and of grand colour. In size it may become larger than required, if the cultivation be too liberal. Sutton's Pomegranate is a pretty fruit, and admirers of yellow-skinned Tomatoes may choose between Prince of Wales, Golden Queen, and Sunbeam.

From the Royal Horticultural Society's Gardens at Chiswick was shown a collection of Pears and Grapes. Some of the bunches of Grapes, such as Gros Guillaume, from the large vine, were unusually large.

Small stands of fruit were exhibited by Mr. W. HORNE, Perryhill, Rochester; and Mr. B. WELLS, The Fruit Nurseries, Crawley; and a larger collection from Messrs. S. SPOONER & SONS, Hounslow.

Messrs. JNO. LAING & SONS, Forest Hill Nurseries, London, contributed a table of fruits; and in a small group upon a table some seedling Begonias from the open ground were shown. The different colours were represented in good strains. This firm also staged upon the floor near to the Orchestra an admirable group of plants, inclusive of very well-coloured Codieum, miscellaneous stove plants of a decorative nature, and a centre panel composed of double and single flowered tuberous-rooted Begonias in bloom.

Roses were shown by Messrs. PAUL & SONS, Cheshunt; and Messrs. W. PAUL & SONS, Waltham Cross, Herts. The first-named firm had a group of well-flowered Roses in pots, and supplemented these by numerous bunches of cut flowers from hardy plants. The Waltham Cross firm showed cut Roses only, and included some of the newer varieties introduced from Waltham such as Enchantress, Sylph, Queen Mab, &c. We shall probably see no other such exhibit this season.

From Messrs. HARKNESS & SONS, Bedale, Yorks, were shown a number of Gladiolus sprays, and bunches of hardy blooms.

There was a pretty group of stove and miscellaneous plants from Messrs. B. S. WILLIAMS & SON, Upper Holloway, London, N., in which we noted some brightly-coloured Cordylines and Codieums, and a few greenhouse Rhododendrons in bloom.

Messrs. J. CHEAL & SONS, Lowfield Nursery, Crawley, had seven large boxes filled with Dahlia blooms.

Mr. T. S. WARE, Hale Farm Nurseries, Tottenham, had a fine lot of double and single Begonias, and blooms of Cactus-flowered Dahlias.

Messrs. JAS. VEITCH filled a table with plants in flower of Nerine Fothergill major over a carpet of Ferns. These plants, with strong spikes and a profusion of blooms, made a very bright picture.

THE CONFERENCE.

At the first day's Conference, held in one of the Terracottas, Sir TREVOR LAWRENCE, Bart., President of the Royal Horticultural Society, occupied the chair. Mr. GEORGE BUNYARD, of Maidstone, read a paper entitled—

Fruit Culture in Her Majesty's Reign, 1837-97.

He said it was somewhat difficult to carry one's mind back to the condition of fruit-culture that existed sixty years ago, but he asked his audience to pay a visit, in imagination, to a well-kept garden of 1837, to inspect the style of culture then in use, and to take note of the varieties of fruit which were cultivated in it. The writer then drew a picture of such a garden, and incidentally quoted the *Gardeners' Chronicle*, which was responsible for the statement that there were 150 garden Apples in 1837, of which thirty were now in general use. All the espaliers in the garden would be of great age, with perfect bundles of spurs on their old arms, carefully and closely pruned as to their branches, but with roots which had never been disturbed from the day they were planted, probably more than half a century before. In

those days Dessert Apples were smaller than they are now. As to Strawberries, in no class of fruit had greater progress been made. Previous to 1837, Black Prince, Keen's Seedling (1821), and Carolina were the only good varieties; and the gardens of the period were filled with such forgotten sorts as Carmine, Hudson's Bay, Scarlets of several varieties, Rosebery, Cones of sorts, Glazed Pine, Bostock, Chili, and a greater number of the Hautbois and Alpine varieties. British Queen was in commerce in 1840, and President about 1850. The 1842 catalogue of the Royal Horticultural Society gave a list of twenty-six useful varieties, and of about 309 others of no value or synonymous with others.

OLD METHODS OF TRAINING.

In justice to our forefathers, it should be mentioned that they took intense pains and trouble to train their trees: the Peaches, Nectarines and Apricots were taken away from the walls annually; the walls washed with a dressing of soot, lime and sulphur, and soft-soap and clay; while the gathered-up boughs, carefully secured to poles away from the wall, would be cleansed by the snows and rains of winter, and the free current of air. After Christmas, they would be carefully looked over and pruned; each bough and twig would be replaced on the wall with geometrical precision. Such care would be followed by a timely finger-and-thumb practice on the fore-right shoots in April, it being considered sacrilege to "knife" Peaches, &c., in the early summer; and a few leaves would be taken away to assist the fruits to colour. Later on, a careful thinning of the fruit, judicious laying-in of the thinner shoots, and the removal of wood that had fruited, would ensure a crop for the following season. Such care was seldom exercised on wall-fruit in these days, the gardener depending more on his crops from heated and cool houses.

INTRODUCERS OF VARIETIES OF FRUITS.

About this time Messrs. R. Thompson, at the Royal Horticultural Society's Gardens; Ronalds, of Brentford; Wilmot & Chaundy, of Lewisham; Thomas Rivers, of Sawbridge-worth; Osborn, of Fulham; Lee, of Hammersmith; Pearson, of Chilwell; and Chandler, of Vauxhall, were the giants in fruit-tree culture. Probably, also, our landed gentry had more frequent intercourse with the continent, which led to an awakened interest in fruit-growing, and any fruit with a French name was then thought to be worthy of culture, and Britain was flooded with varieties which time and experience have proved to be worthless for our climate. In fact, many were but perry and elder fruits, and probably the continental stocks, as well as most of our British ones, were far from correct to name. Still, some good continental varieties were introduced, which are retained to this day. But no doubt the national dislike to anything foreign operated in some degree against their general adoption in the provinces. Meanwhile new methods had appeared on the scene.

DWARFING STOCKS AND GLASSHOUSE CULTURE.

The introduction of glasshouses heated by hot-water, and the removal of the duty on window-glass, at once gave an impetus to fruit-culture. At first Grapes felt the benefit of the change, and later Peaches and Nectarines; but when Thomas Rivers of Sawbridge-worth adopted the Continental practice of using the Quince-stock for Pears, and the Paradise-stock for Apples, the old saying, "plant Pears for your heirs," was exploded, and the marvellous little pyramidal trees, a yard high, producing fruit in abundance, and bush-Apples with a crop that would weigh down the trees themselves, at once became the rage. These fancy trees, combined with Mr. Rivers' practical treatise on "Root-pruning, Summer-pinching," &c., laid the foundation of that marvellous culture of garden fruit which had placed our British produce in the foremost position, whether for size, beauty, flavour, or quality, and had by degrees made what were the luxuries of the few in the past, the inheritance of all classes. For example, good Grapes, once 25s. or 30s. per lb., could now be had from 1s. to 2s. 6d. The abolition of the duty on glass in 1845, the modification of the timber duties in 1830, practical application of hot water for heating purposes, dating from 1821; the introduction, by Mr. Edward Weeks, of Chelsea, of his tubular saddle boiler in 1835; the introduction, in 1839, by Mr. John Weeks, of his upright boiler; and the use of steam saws and planes for cutting out and shaping suitable timber for rafters, sashes, &c., together with the assistance of railways, steamships, and canals were all factors which had brought about the present state of perfection.

ROOT PRUNING AND FEEDING.

In our time every good gardener had added to the regular garden routine—root-pruning of all fruit trees that grew so rapidly as to become void of fruit-buds. This practice had, perhaps more than any other, helped on the culture of garden fruits, and by maintaining a proper balance between the anchor roots, which developed the woody growth, and the upper or fibrous roots which were supposed to nourish the fruit, had thereby ensured success should the English spring weather prove favourable. There was no doubt that root-pruning, combined with the summer mulching and feeding of those trees that were carrying heavy crops, embodied the most conspicuous advance in fruit culture of the Victorian period.

FRUIT SHOWS AND CONFERENCES.

The increase in the size of exhibition Apples and Pears had been wonderful, even those varieties figured so recently as 1855 in the *Herefordshire Pomona* were now exhibited of double the size. A large share of the present practical store of knowledge we possessed as to varieties, culture, and novel-

ties, must be justly said to be due to the energy and taking reports of the horticultural press of the past, not forgetting the publications of the Royal Horticultural Society and its valuable work at Chiswick, where so many fruits had been grown, tried, and reported on the most valuable of the Royal Horticultural Society's sided work was the awarding of Certificates, thus stamping them with its authority, and helping to notice many little-known and valuable varieties, alluded to the pomological literature of the period, he awarded the palm to the late Dr. Hogg, and referred to the excellent work done by writers on the subject, he went on to say he could the greatest direct benefit to fruit culture, so far as was concerned, was derived from the 1883 conference at Chiswick by the Royal Horticultural Society, conference not only brought some fine, but little varieties to the front, but what was of more importance, a list of synonymous names was a wholesale error in nomenclature corrected; and as a landmark, and a starting point for much that was done in London and the provinces; and the great Show of the Fruiterers' Company, held as it is the heart of the city, served to convince that that grand fruit could be and was grown in this. The other conferences, and the great fruit-shows at the Crystal Palace Company, accurately gauged the progress. The Royal Horticultural Society's 1894, 1896 Palace Shows had brought together such collections of autumnal fruits as had never been before seen; a satisfactory find new exhibitors coming to yearly from all parts of the kingdom. Success in fruit for market could only be secured by bringing methods to bear on farm fruit-culture. The tables of the Board of Trade showed an enormous increase in land laid down to fruit; and where this done, fruit growing became a paying industry, as the commercial activity of the fruit-tree nurserymen present time, and the desire to excel in friendly co-operation in fruit exhibitions.

THE BENEFITS DERIVED FROM THE CONSUMPTION.

The placing before the public of examples grown and care, the introduction of novelties, and the prep. red catalogues of the trade had, he believed, beneficial factors in the general advance made culture; tending to popularise the growth of whether for pleasure, profit, or as a hobby, to the advantage of the public in the matter of wealth and in fact, he would go even further, feeling convinced this particular matter, that a great measure of the health of dwellers in large towns was to be directly the cheap supplies of fruit and vegetables place their reach by the commercial energy of markets and distributors.

COUNTY COUNCIL LECTURES.

Still further, benefit was to be expected in the result of the practical lectures now given by County experts in fruit-districts among the intelligent classes. In conclusion, the writer said he felt would be agreed that the rate of progress in horticulture had been quite as rapid and far-reaching as in many of industrial arts and sciences, and he looked forward to greater progress in the future among intelligent gardeners, nurserymen, and hybridists, time, who were not slow to avail themselves of opportunities that lay around them.

FRUITS OF THE LAST SIXTY YEARS LIKELY TO BE PERMANENT ADDITIONS.

Mr. BUNYARD had some most valuable and appended to his paper. In these he gave a complete list of fruits in cultivation in 1837, of notable fruits to commerce in 1837 to 1897 with their dates; and list of the best fruits noted by the *Gardeners' Chronicle*, November, 1841. He also prepared the following fruits of the last sixty years likely to prove permanent additions:—

Apples.—Allington Pippin, Cox's Orange, Bramling, Gascoigne's Scarlet Seedling, and Grenadier.

Pears.—Beurré Hardy, Beurré Superfin, Doyenné du Comice, Emile d'Hayst, Fondante de Marguerite Marillat, Marie Benoist, Olivier des Saumons Duchesse, and Thompson's.

Plums.—Comte d'Arthem's Gage, Jefferson's (J) Pond's Seedling, Transparent Gages, Rivers' Cass Prolific, and Rivers' Monarch.

Cherries.—Early Rivers, Emperor Francis, Bigarreau, and Ludwig's Bigarreau.

Figs.—Bourjasotte Grise, Negro Largo, St. Jo Violette Sepor.

Grapes.—Muscat Hamburg, Madresfield Court, Pince.

Damsons.—Frogmore Prolific, and King of Dams. *Raspberries*.—Baumforth's Seedling, Hornet, Wonder, and Superlative.

Strawberries.—Auguste Boisselot, Countess, H. Thury, President, Royal Sovereign, Sir Joseph Pa Sir Charles Napier.

Nectarines.—Dryden, Early Rivers, Humboldt Napier, Pine-apple, and Stanwick Elrige.

Peaches.—Early Amosden, Early Alexander, H. Watson (these four are American), Alexander Dymond, Goshawk, and Glidstone.

The Discussion.

The President expressed the opinion that the meeting had taken a very interesting paper. No doubt Mr. Bunyard had taken immense trouble to prepare it, and it would have to be read and studied before they could fully appreciate its merits. He thought that person must be blind who could not see that during the Queen's reign the advance in the cultivation of fruit had been made by leaps and bounds. He had recently been staying in a remote district in South Wales nearly 300 miles from London. At Pembrokeshire, the county in question, he had been able to buy most excellent Muscat Grapes for 1s. 6d. to 2s. per lb., and he was quite certain that if he had wished to buy such Grapes in the London market twenty-five or thirty years ago he would probably have had to pay 7s. 6d., 10s. 6d. or even 15s. per lb. That state of things was, however, confined to the United Kingdom. He happened to be in Geneva during the time of last year's exhibition, and while there he was supplied by a member of the Rothschild family with some magnificent Grapes. He was certain from the expressions of surprise on the part of the attendants at his hotel, that they had never seen such fruit before. As to the size of Apples, he could not help saying that he did not attach great importance to that. If increased size meant the sacrifice of quality, he would prefer quality, as he cared no more for a 14-oz. Apple than he did for a 6 feet 4 inch man if the quality suffered. He thought it but right to mention that the gardener at Geneva, under whose care the Grapes sent to him were grown, was without doubt an Englishman, his name being John Smith.

Touching on the question of farming, he said he had recently experienced that many people who professed to understand farming, did not know how to make butter. Unfortunately, farming was not in the hands of people who could learn rapidly. He believed it was greatly owing to the exertions of the people of this country that such great advances had been made in fruit-culture, and great gratitude was due to gentlemen like Mr. Bunyard, who had devoted themselves to improving the industry, and had brought their ability and enterprise to bear in that direction.

Mr. CAMPBELL, of Glestworth Court, Ross, Hereford, considered that farmers approached their work with too much prejudice, and only a few men came prominently to the front by their energy and enterprise. He agreed with the President that much of the butter now made was quite abominable. Alluding to the subject of "packing," he said their watchword should be "honesty." The practice adopted by many growers in packing, arose from the greatest carelessness, but in some cases it was otherwise; and he would impress upon everyone that honesty in packing was not only the proper standard to adopt, but it was the best policy from a financial point of view.

Mr. E. POOLE, F.R.H.S., The Gardens, Clere Hill, Downend, near Bristol, said he made it a rule never to plant more than twenty sorts of Apples; and in packing, their maxima there was, "No tops or bottoms, but the same quality all through." He attached the greatest importance to grading through. He would impress upon everyone that it took no more and he would grow good sorts than it did bad ones. He also mentioned that in his neighbourhood there were orchards which had not been disturbed for forty years.

Mr. PEARSON, Chilwell, said although his experience did not extend over sixty years, yet it had been considerable, and he never knew Apples to grow well where Apples had grown before.

Mr. ROUPELL, London, said he was of opinion that the trained trees of fifty or sixty years ago were far superior to those of the present day. Everyone had gained enormously through the introduction of Cox's Orange Pippin, and if they had nothing else to boast of, that variety was one of which they might always be proud. As to growing for profit, he would only call their attention to what had been done with the Strawberry and the Tomato. There was practically an unlimited demand for Tomatoes, and all that was essential was that they should be sent to market in good condition. The Tomato was not now so much used as a vegetable as a fruit, and he scarcely sold a pound of Tomatoes except for dessert purposes or for salads. There was a great demand for the five-to-the-lb. smooth variety, and little for the corrugated ones. He believed money might be made by growing Tomatoes, but their culture should be carried on near London so that they should not be handicapped by heavy railway rates.

Mr. JOHN WRIGHT proposed a hearty vote of thanks to Mr. Bunyard, to whom he said they were under great obligations. He thought it only right to call to mind a fact which Mr. Bunyard's modesty had prevented his mentioning, and that was, that had it not been for Mr. Bunyard, the old hall Show of 1890 would never have been held. Much opposition and adverse criticism had to be encountered, but Mr. Bunyard's foresight and determination overcame all difficulties. That exhibition was a magnificent one, and a good game of it. Gardeners were greatly indebted to the nurserymen of this country for providing such excellent healthy trees at such reasonable prices. In old days people raised their own trees in various ways from seed, and grafting, and they filled the country with a lot of worthless stuff, which was a disgrace to the nation. All that had, however, been altered by the nurserymen of England. The new having been heartily carried.

Mr. BUNYARD, in response, assured the meeting that the nurserymen were doing their best for the industry. He agreed with much that had been said about reducing the number of varieties, but the requirements of the market had, of course, to be studied.

MARKETS.

COVENT GARDEN, OCTOBER 7.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

NOTICES TO CORRESPONDENTS.

ARALIA: B. & Son. The creatures which are swarming on the leaves belong to the genus *Tarsonemus*, a very small Acarus; but in spite of its minuteness, it is most destructive, and is very difficult to get rid of, because it is a leaf-mining thing, and it is almost impossible to reach with any chemicals any except the few that are wandering outside. Fumigation would be useless; the best thing to do is to carefully burn all infected plants, and all debris and stuff that has been near them, and to keep on doing this. But if you are unwilling to do this, you might try spraying upward, so as to wash the undersides of the leaves, at frequent intervals, either with paraffin solution or cresote solution, without soap, so that it may penetrate as much as possible. *Albert D. Michael.*

BOOKS ON FRUIT CULTURE: C. F. R. If you require manuals on the out-of-door cultivation of fruits, you should obtain *Fruit Culture for Small Holdings*, by J. Cranston (Hereford: Messrs. Jakeman & Carver); or *Fruit Farming for Profit*, by G. Bunyard (Maidstone: Frederick Bunyard, 29, Week Street). For Vine culture under glass obtain *Vines and Vine Culture*, by A. F. Barron, 2nd edition, to be purchased of the author, 13, Sutton Court Road, Chiswick.

ULIAS.—Any limitation of the number of varieties must, of course, be an old Juarezi was styled a nurse, in some measure, it some kinds of Cactus crossings, this character to many other view these National certificate

is awarded to a seedling variety in the Cactus section, the blooms must exhibit the peculiarity referred to above in an unmistakable degree. Any that do not do this, and are not "show" varieties, are relegated to a section known as "decorative" Dahlias, though they may have resulted from a cross in which one or even both parents were known as Cactus-flowered sorts. We see no objection to this, because in order to introduce as much variety amongst Dahlias as possible, the peculiarities of each type should be developed as much as possible. The same difficulty has arisen in the case of incurved Chrysanthemums. Of course a nurseryman may, for his own purposes, classify a variety as he chooses. The blooms you send of your new Dahlia Queen Victoria are purer white than any Dahlia we have previously seen. The stems are long, the habit good—indeed, better than any other white Dahlia we can call to mind; but it may not be sufficiently Cactus-like to be classed as such by the florists. For our own part, we should describe it as the best white flowered decorative Dahlia existing.

CALVARY CLOVER: *W. T.* *Medicago echinus.*

CARNATIONS: *L. B.* Your leaves are badly affected with the rust-fungus (*Helminthosporium echinulatum*), see *Gardeners' Chronicle*, August 21, 1886. It is very likely to spread. Burn all affected leaves immediately, and spray the healthy plants with weak Bordeaux Mixture or weak Condry's fluid, as a preventive.

CHRYSANTHEMUMS ATTACKED BY A RUST: *H. R., Col. B., Constant Subscriber, and others.* The same disease as that of "A Constant Subscriber." It is a rust, and is called *Uredo Hieracii*. It is useless to apply sulphur; but, perhaps, if the under-surface of the leaves could be syringed with Condry's Fluid, as was recommended in the *Hollyhock* disease, it might be beneficial; but we fear that no cure has yet been found. *M. C. C.* [See also an article on p. 256.]

CHRYSANTHEMUM ROOTS DESTROYED: *G. S.* The grubs present in the soil are those of the Daddy-longlegs. See answer to *GRUBS*, *W. Lewis*, p. 244, in last week's *Gardeners' Chronicle*. You should use a soil quite free from the grubs.

DAHLIA SPORTS: *A. B.* Grow each of them another season, and you will be better able to estimate their value. There are already varieties having white petals margined with yellow. In your flowers the ray-florets or ligules have two supplementary petals. This is interesting as showing the true conformation of the floret which really consists of five petals united, though apparently one only is fully developed. That one is really three fold, so that the additional two in your specimens make up the five. If you could succeed in increasing the size of the two additional petals, you would get a startling novelty.

DESTRUCTION OF CABBAGES: *H. H.* Grubs of Cockchafer; dig up the soil, leave it open, and encourage rooks and starlings.

FIG LEAVES DISFIGURED: *S. C.* The Fig leaves appear to be in a bad state, but from them we cannot determine what ails the tree. There is no positive fungoid disease, although the spots resemble those caused by *Uredo ficis*, which has not yet been recorded in Britain. We fear it is rather an error in cultivation than organic disease. *M. C. C.*

FUNGUS: *Agaricus.* The edible *Agaricus rachodes*.

INSECTS: *Allerton.* We do not know what insect has eaten your *Rhododendron* leaves. Send us the culprit and we will endeavor to name it for you.

RISH PEACH-APPLE: *R. W. R.* The tree bears at the extremities of the shoots, and should be pruned accordingly, and not like other Apples that bear on short spurs for a considerable distance along the branches.

KALES ROTTING: *G. A.* The plant of which a part is sent is probably affected by a slime fungus, *Plasmodiophora Brassicae*, the same which is the cause of Club-root, Finger-and-Toe, &c. The spores remain in a resting state in the Cabbage, Turnip, &c., during the winter, and in the spring they are ripe and ready for germination; hence the necessity to get rid of every infected plant, leaves, root, stem, and all by burning as soon as it is noticed. To leave Club-root refuse on the ground or throw it on the dung-heap is a certain method of propagating the disease. You must not crop the land with Brassicas for at

least three years. Professor Jamieson, some years ago, advised cultivators not to use manures containing sulphur and chlorine; the one given usually as sulphuric acid and sulphate in dissolved or soluble manure; the others, in chloride, muriate of potash, and in common salt, the fungus spores finding sustenance in the sulphurous materials. Do not therefore use superphosphate of lime. Do not let Charlock grow about the garden, it being also liable to attack from the same species of fungus.

LYCUM BABARUM: *W. T.* Introduced in 1696, and probably cultivated in the Duke of Argyll's garden at Whitton. We have never heard of its use as tea in modern times.

MELONS: *F. G. G.* There is no evidence of Bacteriosis at present in your Melon stems, but it may be an incipient form of that disease. We can find no mycelium in the discoloured tissues. The appearance of the stems is very like that of the Sclerotium disease of Potato haulms, described and figured in the *Gardeners' Chronicle*, which disease we have also recorded as attacking the stems of Cucumbers. As the disease is internal, we can suggest no remedy. *M. C. C.*

MUSHROOMS: *A. M.* No, certainly not a Mushroom; but the specimens were not packed with sufficient care to enable us to determine them.

NAMES OF FRUITS.

*Applications to name fruits are so numerous at this season, as seriously to hamper us in the exercise of our editorial duties. They entail an expenditure of time, labour, and money, of which our readers can have little idea. We are most desirous to oblige our correspondents as far as we can, but we must request that they will observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones, just approaching ripeness, and they should be properly numbered, and carefully packed. We do not undertake to send answers through the post, or to return fruits. Delay in any case is unavoidable.

F. F. Ross, Finchley. 2, Blenheim Orange; 4, do.; 21, do.; 3, Court of Wick; 9 and 37, Fearn's Pippin; 22, Landsberger Reinette; 19, Golden Noble; 34, King of the Pippins; 23, 25, 27, 28, 44, Dumele's Seedling; 9, Scarlet Pearmain; 26, 50, Alfriston; 21, Pine-apple Russet; 20, Blenheim Orange; 51, Ribston Pippin; 47, Ecklinville; 48, Cox's Pomona; 49, Golden Noble; 32, Braddick Nonpareil. Pears are both Catillacs. We only undertake to name six varieties at any one time. You have been inconsiderate enough to send sent us no fewer than forty; of these we name about one-half. As you have so greatly exceeded the number, and put us to so much trouble and loss of time, the least you can do is to give a small amount to the *Gardeners' Orphan Fund*.—*M. Dixon.* 1, Old English Codlin; 2, Frogmore Prolific; 3, Royal Somerset; 4, Lane's Prince Albert; 5, Bess Pool.—*E. C.* 1, Lord Grosvenor; 2, Colonel Vaughan; 4, Beurré Bachelier; 5, B. Clairgeau; 6, Marie Louise d'Uccle.—*J. Russell.* 1, Beauty of Kent; 2, Round Winter Nonsuch; 4, Striped Beefing; 5, King Pippin.—*W. J. Bligh.* Two of the Apples are Warner's King, but we can find no numbers to the fruits.—*M. F.* Your Pears are too much over-ripe and bruised for us to determine.—*H. C.* Please send another specimen.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*Melville.* *Colutea arborescens* (Bladder Senna).—*Alloy.* *Acer Negundo*.—*C. B.* *Glechoma hederacea*, the variegated variety.—*G. P.* We are not able to name your variety, which, however, looks like the white Clove.—*C. W.* 1, *Berberis stenophylla* ×; *Berberis empetrifolia*; *Pyrus*: 1, *Pyrus intermedia*; *Acer*: 5, is *A. circinnatum*. It is not possible to name the species of *Philadelphus* from leaves only.—*W. B.* 1, *Ligustrum lucidum*; 2, a species of *Ash*, *Fraxinus*, which we do not recognise; 3, *Rhus Cotinus*; 4, *Ruscus hypophyllum*; 5, *Euonymus europæus*, common Spindle-tree.—*P. C. P.* *Escallonia illinita*.—*A. P. H.* *Eria convallarioides*.—*J. J. J.* The true Service-Tree (*Sorb.*) is *Pyrus Sorbus*, a very different plant, with pinnate (not simple) leaves, like those of a Mountain Ash. Your tree is *Pyrus auricularis* (*P. Bollwylliana*), a natural hybrid between the Pear (*Pyrus communis*) and the White Beam (*Pyrus Aria*).—*J. A.* We cannot name the variety of *Clematis*.—*Barr & Sons.* *Diospyros virginiana*.—*Japonica.* 1, *Thuya orientalis* variety, perhaps the one known in nurseries as *japonica*; 2, *Crataegus tanacetifolia*.—*O. G. H.* *Cape Town.* *Abutilon megapotamicum*.—*Jas. F.* 1, *Cotoneaster frigida*; 2, *Platanus orientalis*; 3, *Kölreuteria paniculata*;

4, *Quercus Phellos*; 5, *Staphylea pinnata*; *Quercus rubra*.—*W. H. M.* 1, *Polygonum*; *Actinidia*; 3, *Actinidia*; 4, undeterminable; *Acer Negundo*; 6, *Acer rubrum*; 7, *Acer rubrum*; 8, *Alnus glutinosa lacinata*; 9, *Cimicifuga c. folia*; 10, *Myrtus apiculata*; 11, *Abelia unifl.* 13, *Eupatorium odoratum*; *Rondeletia speciosa*, a *Ceanothus* without numbers. The specimens are very poor ones, and most of them unaccompanied with flowers.—*Norwood.* Rose, *Madame Pierre Cod*.—*J. M.* *Poterium caudatum*.—*P. A.* *Wokingham.* Your two grand spikes of *Dendrobium Phalaenopsis* *Schroderianum* represent one of the best varieties of that favourite Orchid which we have seen. They are also the best spikes seen this season, and the good cultivation necessary to produce so reflects great credit on the grower.—*G. W.* Yours is *Dendrobium Phalaenopsis* var. *delicata*. It could not be called "white." The leaf and flower are those of *Cyrtodeira* (*Episcia*) *fulgidula*. *S. L.* *Catasetum viridi-flavum*.

PEARS DEFORMED: *C. D., E. M. H., and others.* The true fruit of a Pear is the core; the edible portion is only a dilated condition of the flower-stalk. In your specimens, for some reason which we do not know, the true fruit or core is not formed, but the thickened flower-stalk has taken on fresh growth and thus arises the appearance of two Pears, one coming from the other. Such changes are common and have often been figured in our columns. The term "freak of Nature" is quite inapplicable. "Nature" is not capricious; there is a purpose in all her work, though we are sometimes too blind or too ignorant to see it.

"PIPLESS" FRUIT: *G. L.* We do not believe there is any treatise on the production of pippless Orange Apples, Grapes, &c. The condition arises either from abortion or incomplete fertilisation.

PLUM TREES: *A. F.* Do not prune over-much, but get the trees into bearing by transplanting, and doing this, bring all roots to within from 4 to 6 inches of the surface. Remove tap-roots, and shorten the longest horizontal ones somewhat. Afford the trees no manure, but add some good sound fresh loam and mortar-rubble to the step and see that the border is not water-logged.

POTATO: *W. H.* Nothing unusual.

SCOLOPENDRIUM VULGARE VAR. CRENATUM: *H. C. Geneva.* This variety frequently bears the spots on the upper surface; the scurfy veins seen on the margins of the incisions, develop the spots more or less on both sides of the foot. *C. T. D.*

SEEDLING FIG TREES: *A. F.* It may be many years before your trees will bear fruit if left in the ground; better keep them in pots not exceeding 8 to 10 inches in diameter, potting them firmly in loam, cutting them back in late winter, and fruit them in an intermediate house.

SPARROW-TRAP: *Swanley.* You should enquire the Horticultural Sundriesmen.

VINE FOLIAGE, SHOOT, AND FRUIT: *J. S.* Vines have been over-cropped probably, and are wisely mismanaged; but the size of the bunches, individual berries, and the stoutness of the foliage show that the Vines, under more skilful management, with perhaps some renovation of the buds and a rich annual top-dressing, will give an account of themselves another year.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the honor of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper, MORE THAN DOUBLED, and that it continues to increase week after week. Advertisers are reminded that the "Chronicle" circulates among GENTLEMEN, AND ALL CLASSES of GARDEN-LOVERS at home, that it has a special FOREIGN AND COLONIAL CIRCULATION, and that preserved for reference in all the principal Libraries.

THE Gardeners' Chronicle.

SATURDAY, OCTOBER 16, 1897.

PLANTING FRUIT-TREES.

MUCH valuable information in reference to the planting and culture of fruit-trees has appeared in the pages of the *Gardeners' Chronicle*, but every year brings fresh readers who are seeking instruction, and it seems only fair to attempt making some return for useful knowledge gained by communicating a little from our own experience. To review the whole subject of fruit-planting would occupy more space than the editor would care to devote to one subject, however important it may be, therefore we will glance at a few of the chief points.

Differences of opinion exist as to the best season for planting, a few maintain that spring-planting gives the best results; more regard the whole season from autumn until spring, i.e., October to March, as suitable when the weather and soil conditions are right, and a large number are distinctly in favour of autumn-planting. Amongst the last-named, I must include myself for reasons which experience confirms more fully every season. My opinion is founded upon observation with many thousands of trees which have been planted at various times, and under diversified conditions, and the results have been so uniform that it may perhaps be excusable if confidence is strong in the method adopted. Large numbers of trees have been planted in different, and sometimes unfavourable soils, and subjected to trying weather conditions for a year or two after, with a maximum loss not exceeding one per thousand in any case, and in most instances without a single loss. On the other hand, spring-planting has been most uncertain, sometimes the losses have been few or more, but, occasionally, the results have been very discouraging.

If planting can be commenced in late October or November—as soon, in fact, as the leaves have fallen—the roots injured in lifting heal more readily than at any other time; the trees have time to partially overcome the effects of transplanting before the heat and drought of spring or summer come upon them. When, however, the planting is intentionally or unavoidably delayed until spring, the buds often start before the roots are prepared to supply their demands, exhaustion, and perhaps death, following. Still, apart from the actual time chosen for the work, the weather and soil-conditions require the closest attention, for I have no hesitation in saying that good or bad results depend more upon these than upon anything else. The greatest skill and care avail but little if heavy soil is being dealt

with, and planting is attempted when it is wet and clogs round the roots. In some clayey soils the clods will dry into hard lumps like pieces of half-baked brick, either encasing the roots, or presenting an impassable barrier to their progress. Even the holes that are dug under such conditions have the sides cut sharp and smooth by the spade, and will commonly form a kind of basin, which will retain water for a long period in wet weather, and is almost as impenetrable to roots as the sides of a flower-pot. It seems scarcely possible that so little judgment could be exercised as to attempt planting in this way, yet it is unquestionably done, as several deplorable examples have come under my own observation. In one instance I was called in to investigate the cause of a number of young Apple and Pear-trees not thriving, and a pitiable spectacle they presented. They had been planted two years, but none had made more than an inch or two of weakly, pale growth; some branches were dead, and in other cases the whole tree was obviously dying. Upon lifting a few of them, the chief cause was apparent, they had been planted when the soil was wet and pasty, and being of an adhesive character, it had set hard round the roots, which had been quite unable to make any progress. By carefully lifting the whole of these trees, and well pulverising the soil when it was sufficiently dry, incorporating a good proportion of fertile friable soil, trimming and spreading the roots, and cutting-in the branches, a considerable improvement was effected, and the following season fair growth was made. The stunting effect of bad treatment upon young trees is not, however, very quickly recovered from entirely; indeed, in some instances and with delicate varieties the evil effects can be traced throughout the life of the tree. Another deplorable instance of failure with a large plantation of Pears came under my observation which was undoubtedly partly due to the same cause as the above, the other portion of the evil effects being the result of an unfavourable situation.

The preparation of the land for the reception of fruit-trees is also an important matter too often overlooked or imperfectly performed, and though we are here referring more particularly to cases where plantations to some extent are about to be formed, yet the care advised is equally needed if only a few trees are to be planted. The first consideration is the thorough breaking up of the soil, which is best effected by means of trenching, at least for the stations the trees are to occupy; ordinary ploughing is of little use, not because a great depth is required for the roots, but because it is necessary to ensure effectual surface drainage, to increase the air containing capacity, and consequently the warmth of the soil. In a cold soil laden with stagnant moisture, tree-roots can make but little satisfactory progress, and the branch-growth will correspond; indeed, it is not recognised sufficiently how much the one is dependent upon the other. Coarse roots produce rank branches, and stunted roots result in impoverished stem growth. I have often when lifting or transplanting been struck with the resemblance between the two portions of a tree: strong downward-going roots being associated with vigorous upward stem-growth, while abundance of horizontal fibrous roots commonly have a corresponding spreading stem habit.

In the case of all soil of a doubtful or unknown composition, it is, however, judicious to keep each layer in its respective position; in other words, to avoid bringing the lower soil to the surface or where the roots of the trees are to be placed. I have seen such disastrous results follow inattention to this, that I consider it a matter which cannot be too strongly impressed upon learners. Wherever it is desired to

increase the depth of surface soil, portions of the lower layers must be brought up gradually, and then only when the land is being cropped with strong-growing vegetables.

As a means of preparing rough imperfectly cultivated soil for fruit trees, and for cleansing ground that is infested with weeds, it is a wise precaution to crop it with Potatoes the summer before planting is intended to be commenced. Where this is done, however, the land should have a liberal application of stable or artificial manure, as Potatoes use up a quantity of potash, the very constituent that is of much importance to fruit trees. Clearing the ground is a first consideration, for it is the extremity of folly to plant trees where the operation of hoeing or weeding will be a most difficult one for years, particularly if "twitch" should be present. With the latter weed, in fact, it is essential to deal most thoroughly in the direction of extermination prior to planting, Bell-bine, Thistles, and Docks being scarcely less troublesome. Unless there are many other advantages in its favour, I should never plant a piece of foul land with fruit trees; but occasionally there may be no choice, and the only alternative is to render the land as clean as possible by persevering labour.

The question of distances and arrangement is an important one, and it is not surprising there should be some divergence of opinion respecting it. When land is closely cropped with bush fruits or Strawberries, in addition to the Apples, Pears, or Plums that form the staple, the difficulties of cultivating and cleaning the land are greatly increased; on the other hand, if we do without what may be termed under-crops, the producing power of the land is materially decreased, unless some intermediate crops can be taken while the trees are growing into bearing size. Early returns have to be balanced against reduced cost of cultivation, and where the fruit plantation is the main source of the grower's income, the former consideration will predominate; but where it is only adjunct to some other occupation, it may possibly suit the fruit-grower to adopt the second method. It may also be to some extent a question of means, for the capital expenditure on a large plantation in which small fruits are included would be more than doubled if all the bushes, &c. have to be purchased. For standard Apples a less distance apart than 20 feet cannot be allowed, and then only for small-growing varieties, while 24 to 30 feet are preferable in all respects. I do not however advocate tenants planting standard Apples. The owner of a piece of land who wishes to increase its permanent value may do well in planting standards, for the number per acre is not large at the distances named, but a lessee or land-holder, on more uncertain tenure, can better secure a quick return for his outlay and labour by planting dwarf-trees. That at least is my experience, and that it has proved equally desirable in many other cases I am well aware. Dwarf-trees too can be placed at 7 to 12 feet apart according to the habit of the variety, and the future plans of the grower, and a large number per acre can thus be arranged for.

As to methods of arrangement, there is none on the score of convenience for working and good appearance to rival planting at equal distances between the rows and between the trees, so that the trees are in squares, thus admitting of working the land up the rows, and again at right angles. When accurately distanced, this method also gives a beautiful effect as the trees advance, for they come into lines in so many different directions.

Whether stakes should be employed or not will depend upon the form of trees planted, and the position; but perhaps more upon the latter than anything. In sheltered places I have planted standards without stakes that have made as good progress, and have their stems as straight as those that have been most carefully staked in more exposed spots; but in a general way the expense and trouble of staking should always be incurred for standards. With dwarf trees it is not always needful—indeed, it may be said that only in exceptional cases of great exposure is it essential.

As to the most desirable depth for planting fruit,

there cannot be much difference of opinion, for the slightest experience shows that in all soils of a fairly retentive nature, planting at any depth below the nursery-mark is productive of much mischief; where the soil is light, deep, and equally good in the lower layers, slightly deeper planting may be the means of preventing too much exhaustion by summer droughts. In heavy soils resting upon clay, or other unfavourable sub-strata, I always place the roots as near the surface as will admit of their being adequately covered with soil; indeed, in some extreme cases, planting upon the surface and mounding over the roots, has proved preferable to the conventional system of "digging a hole." Whatever system is adopted, two points are essential, one being to trim off all jagged or injured roots with a sharp knife, and the other is to spread the roots evenly and horizontally. If the occasion should arise to examine the cut-roots a year or two after planting, the effects will be seen in the thorough healing and production of fibrous roots from the ends, a multiplication of "feeders" most useful to the tree. With regard to the other practice, the chief object is to prevent the roots extending downwards, and to keep them in some measure under control; every interstice being filled with pulverised soil, as great gaps between the roots are decidedly antagonistic to their progress.

The question of varieties has not been entered upon in these notes, first, because it would require an article as long as this to deal with it thoroughly; and secondly, because the selection for market purposes must depend upon so many circumstances that the intending planter has often to be guided by local knowledge. *Practitioner.*

NEW OR NOTEWORTHY PLANTS.

LÆLIA PUMILA "GATTON PARK VARIETY."

In the *Gardeners' Chronicle* of January 2, 1897, p. 11, the pure white *Lælia pumila* alba, "E. Ashworth," was illustrated, and now there has appeared in the gardens of Jeremiah Colman, Esq. Gatton Park, Merstham, Surrey (gr., Mr. King), an extraordinary coloured variety well worthy to rank with the first named. So thought the Orchid Committee of the Royal Horticultural Society when they awarded a First-class Certificate to the plant (fig. 79) at the Drill Hall meeting on September 21 last.

In size and form, the flowers are identical with those of *L. pumila*, but it is novel in colour, its sepals and petals being white suffused with a decided blue tint. The labellum also is tinged with various shades of blue, which deepen in the anterior portion into light bluish-purple. *J. O'B.*

EULOPHIA WENDLANDIANA, Kral. (§ PULCHRAE).*

This is yet another discovery of the late Johannes Braun during his last visit to Madagascar. The plant most resembles *Eulophia pulchra*, Lind., *E. alimatifolia*, *E. megistophylla*, *E. sclerophylla*, Rohb. f., and other species, all described by Reichenbach; but on the other hand it recalls *E. euglossa*, Lindley, a

plant of western African origin. In colour and habit it resembles a good-sized *E. pulchra*, but the middle lobe of the lip is longer and narrower than in that species, without the slightest trace of becoming bilobed itself, as is the case in all the other species of this group. The margin of the middle lobe is slightly waved, as are the two larger, and the adjacent two smaller elevated lines or crests on the disc of the lip. It is after all, a *Eulophia* with an affinity to *E. pulchra*, with some traces of *E. euglossa*. The flowers are not of great beauty; they are nearly 1½ inch in diameter; the petals are coloured pea-green, the oblong, blunt petals pure white, and the lip is green profusely tinted with amethyst. *F. Kröplin.*

FRANCE.

M. LEMOINE'S NURSERY AT NANCY.

(Continued from p. 249.)

In the beginning of this note we alluded to the wonderful collections of herbaceous plants and bulbous plants to be met with in this nursery, and

Among other shrubs mention may be made of *Panax sessilifolium*, with compound leaves and large compact balls of black berries, greatly resembling those of Ivy, but much larger. A glaucous variety of *Sambucus racemosa* is pointed out, and a feathery *Tamarix*, known as *T. kasgarica*. It is very like its congeners, but has the useful quality of flowering even late in September. *Rosa calocarpa* × is a hybrid from *R. rugosa*, and laden as it was with its orange-scarlet berries, it formed a most ornamental bush. *Aronia erythrocarpa* is remarkable for its deeply coloured leaves and pear-shaped black berries, and *Fraxinus rhyucophylla* is noted as a fine and distinct member of the genus.

A hybrid between *Clematis Davidiana* and *C. stans* shows the erect habit and the masses of tubular lavender-coloured flowers characteristic of this section, and is looked on with favour by M. Lemoine.

Eulalia gracillima is a very ornamental grass of the first magnitude, with a dense profusion of elegant linear leaves, each marked with a white stripe in the centre.

Berberis Knighti is noted as having been nearly lost to English gardens. *B. virescens*, *B. Thunbergii*, with its deeply coloured leaves and an endless series

FIG. 79.—LÆLIA PUMILA, "GATTON PARK VARIETY."

Sepal and petals pale mauve-blue; labellum pale mauve-blue, with a deep mauve-blue lip, beautifully bordered with a fine white line.

* *Eulophia Wendlandiana*, Kral. (§ *Pulchrae*). — Tuberiditis crassatis 6 cm. longis, 3 cm. diam., internodiis 6—7 compositis; foliis e tuberidio juniores orientibus 3—4, foliorum petiolis arcuatis plicatis 9—10 cm. longis, foliis ipsis ad 60 cm. longis, 3—5 cm. latis, lanceolatis acutis acuminate nervis 3 v. 5 infra valde prominulis; scapo multoties longiore ad 75 cm. alto, cataphyllis 3 magnis longe vaginantibus inflatis acutis vestitis (maximo 6.5 cm. longo); racemo longissimo (40 cm.) plurifloro distantifloro (minime paniculato); bracteis infimis linearibus quam ovaria subbrevioribus supremis multo minoribus ovaria e pedicellis 3—3.5 cm. longis; sepalis late linearibus acutis pallide viridibus 2 cm. longis, 3 mm. latis; petalis oblongis obtusis apice rotundatis, 1.5 cm. longis, 6 mm. latis, albis; labelli subbrevioris lobis lateralibus semi-oblongis v. semi-lunatis supra rotundatis intermedio late oblongo antice obtuso simplici neque emarginato neque sub-bilobato; callis basilaribus 2 inter lobos laterales, continuis cum lamellis 2 majoribus crenulatis, addita utrinque una multo brevior apicem fere usque decurrentibus; calcaris dimidium labelli requante complanato obtuso apice non didymo; labello viridi disco albidio callis basilaribus albis; lamellis disco anteriore calcaris amethystinis; gynostemio leviter curvato, utrinque marginato dorso carinato; anthera supra in processum carnosulum satis latum apice emarginatum acuta. In Madagascar det. et misit beatus Joh. Braun.

more especially to the extraordinary results obtained by M. Lemoine by hybridisation, cross-breeding, and careful selection. To go into details is impracticable, but we may just add a few particulars relating to trees and shrubs; and first we may mention that the Lilas de Varin, or Rouen Lilac, concerning whose origin much doubt has been expressed, and which was at one time even supposed to be a native of Siberia, has been proved to be a hybrid between a semi-double form of the common Lilac, *S. vulgaris*, and the out-leaved form of Persian Lilac, *S. persica laciniata*. *Solvitur ambulando*. The hybrid has been produced in these nurseries from the parents just mentioned. Many of the newer Lilacs originated in this establishment, and we saw many more coming on, but not yet in a state for further mention. The same remark applies to numerous varieties of *Deutzia*, *Ceanothus*, and *Philadelphus*, which were not in bloom at the time of our visit.

of hybrids, were observed the characters of which would take a long time to describe.

A hybrid *Gazania* between *G. splendens* and *G. nivalis* is pointed out. If some of these cross-breeds are not in appearance superior to their parents, they may, and often do, possess qualities which enable them to be grown under conditions and circumstances which are unfavourable to the parents.

Dimorphotheca Ecklonis is a fine *Gazania*-like Composite, which is kept cut back so as to secure a growth of young shoots, many of which flower at the tips.

Diplacus tomentosus is very like the old *D.* (*Mimulus*) *glutinosus*, but has pale saffron-coloured flowers.

But mere lists of names are devoid of interest, and we must await the return of the leaf and the receipt of specimens to describe the many other novelties or plants of interest here to be seen. In the meantime, let no plant-lover who has the chance miss the opportunity of visiting this unique establishment.

PRIMULA TRAILLI.

On April 27 I showed at the Drill-hall a new Primrose, *Primula Trailli*. I received the seed about two years ago from a friend, a good botanist, in the Himalayas, with injunctions to be careful with it, as the plant had not flowered in this country. He

low-growing Primroses. *Primula Trailli* is quite on a different scale, as I think you will see by the illustration (fig. 80). I took the measurements carefully: breadth of plant, $11\frac{1}{2}$ inches; height of the tallest stem, 16 inches; length of the leaf, $6\frac{1}{2}$ inches; expanded part of this 3 inches, the width of the last, $1\frac{1}{2}$ inch. It had ten flower-stems. The plant was

WALNUTS, ALMONDS, AND CHESTNUTS.

(Continued from p. 195.)

We have now to consider the constituents of the ash of the various parts of the fruit of the Californian-grown Walnut, Almond and Chestnut, with such European ash analyses as are available.

First we will quote the average composition of the ashes of the wood of the Walnut and Chestnut trees.

SELECTED CONSTITUENTS IN THE ASHES OF THE WOOD OF WALNUT AND CHESTNUT-TREES.

Constituents.	Walnut Wood.	Chestnut Wood.
	Per cent.	Per cent.
Potash	11.3	10.1
Lime	35.9	43.6
Magnesia	3.7	3.2
Phosphoric Acid	4.1	1.5

The results show that the Walnut-tree consumes more potash in the building up of its wood than does the Chestnut-tree; but on the other hand, the Chestnut-tree makes the largest demand on the constituent lime, there being a difference of about 8 per cent. Magnesia is very similar in the wood of both trees. Phosphoric acid is in greatest demand by the Walnut-tree, to the extent of over 3 per cent.

It is found that the wood of the Chestnut-tree and that of the common Oak are very similar in their chemical composition.

But now our chief care is to look to that part of the tree which is taken away from the orchard—the nut proper, the soil constituents of which must eventually be replaced by the addition of suitable fertilisers. In cases where the hulls and the leaves are returned to the soil, it will be the composition of the ashes of the nut alone, and not of the entire fruit, which will be the proper gauge of the replacement of plant-food necessary.

The following table gives the composition of the ashes of Californian Walnuts, Almonds, and Chestnuts, in the nuts (hulled), and in parts of the entire fruit:—

SELECTED CONSTITUENTS IN THE ASHES OF WALNUTS, ALMONDS AND CHESTNUTS.

The Quantities per Cent.

Constituents.	Potash.	Soda.	Magnesia.	Lime.	Phosphoric Acid.	Sulphuric Acid.
<i>Walnut.</i>						
Nut—hulled ...	19.96	0.83	11.40	23.83	37.17	2.17
Kernel	12.69	0.93	16.60	5.57	57.83	1.31
Shell	28.28	0.82	5.29	44.88	13.14	3.23
Hull	77.80	0.27	1.80	7.70	2.46	2.66
<i>Almond.</i>						
Nut—hulled ...	36.63	2.29	12.23	11.49	28.90	4.12
Kernel	10.96	1.85	18.31	14.53	48.13	4.64
Shell	64.76	2.81	5.54	9.12	7.76	3.55
Hull	64.86	0.74	5.28	4.10	5.62	1.32
<i>Chestnut.</i>						
Nut—hulled ...	45.07	1.70	9.24	8.32	23.10	10.84
Kernel	48.67	1.20	8.05	4.63	23.55	12.81
Shell	29.02	3.92	14.51	27.52	21.10	2.08
Hull	32.23	0.99	10.15	17.83	9.61	5.05

Some striking results are shown in the above table. We find, for instance, that the potash in the ash of the hulled Walnut comprises nearly 20 per cent. of the whole ingredients, while that of its hull alone is nearly four times as much, viz. 77.8 per cent. It will therefore be seen that if the hulls of the Walnut are not returned to the soil, the dominant ingredient of the fertiliser intended for replacement of plant-food must be potash; while if the hulls are left on the ground, the dominant constituent by far should be that of nitrogen.

The ashes of the various parts of the Almond and Chestnut, on the whole, show few such wide differences in potash as that above given, but still they differ much from each other.

It is an interesting fact that the ash of the kernel

FIG. 80.—PRIMULA TRAILLI.

described it as *P. Trailli*, *Watt*, Himalayas, 17,000 feet. In the note on the show in the *Gardeners' Chronicle*, May 1, p. 292, noticing its Award of Merit it is said, "the plant is evidently closely related to *Primula involucrata*." I have long grown what are sold as *P. involucrata* and *P. Munro*, these are much alike, and are both small

grown in a cold frame, and when the light was on, placed close to it, so that it has not drawn. The conclusion I came to was, that with some points of resemblance to *P. involucrata* and *P. Munro*, notably in the very sweet scent, it is essentially distinct, and a new Primrose that will be a valuable addition to the hardy plant garden. *G. F. Wilson*, *Heatherbank Weybridge*.

of the Walnut is, in weight, more than twice that of the shell, while in other nuts it is more nearly equal. Also, that in the kernel of the Walnut and Almond the phosphoric acid is very largely predominant over the potash, while the reverse is true in the ashes of the shell.

In the Walnut kernel, the phosphoric acid comprises nearly 58 per cent. of its ash. In the ash of the Chestnut, the potash is by far the predominant ingredient in both kernel and shell, and is largest in the kernel. The same is found to be true in the case of the European Chestnut. The soda in European Chestnuts is found to be considerably higher than in the Californian fruit.

SOIL INGREDIENTS WITHDRAWN BY NUTS.

From the foregoing data, relating to ash and nitrogen content, we are enabled to calculate the amount of soil-ingredients withdrawn by the growth of Walnuts, Almonds and Chestnuts. These amounts, expressed in pounds for each constituent per 1000 pounds of fresh nut, both hulled and not hulled.

SOIL INGREDIENTS EXTRACTED BY WALNUTS, ALMONDS, AND CHESTNUTS.

In 1000 lb. Fresh of—	Total Ash.	Potash.	Lime.	Phosphoric acid.	Nitrogen.
	lb.	lb.	lb.	lb.	lb.
Walnuts, hulled ...	7.50	1.50	1.81	2.78	10.20
„ not hulled ...	12.98	8.18	1.55	1.47	5.41
Almonds, hulled ...	15.00	5.49	1.72	4.33	16.40
„ not hulled ...	17.29	9.95	1.04	2.04	7.01
Chestnuts, hulled ...	8.20	3.72	0.71	1.89	8.00
„ not hulled ...	9.52	3.67	1.20	1.58	6.40

In the total quantity of mineral matters (ash) withdrawn from the soil, the Almond leads with 17 lb., the Walnut comes next with nearly 13 lb., and the Chestnut last, with 9½ lb. in 1000 lb. of the entire fruit. These figures become somewhat changed when referred to the hulled nuts.

Stone fruits have been found to come much below the above in total ash.

Potash.—The data for hulled-nuts shows that Almonds withdraw 5.49 lb. of potash, as against 3.72 lb. for Chestnuts, and 1.5 lb. for Walnuts, in 1000 lb. of fresh nuts; however, when these figures are referred to the entire fruit, the Walnut and Almond take about the same quantity—8 to 10 lb., or nearly three times as much as the entire Chestnut. Stone-fruits do not, on the whole, nearly approach these figures for equal weight of fruit.

Phosphoric Acid.—The Almond again leads in this constituent, withdrawing 4.33 lb., the hulled nut of the Walnut taking 2.78 lb.; and the Chestnut only 1.89 lb., per 1000 lb. of fresh nuts. These results are again all materially changed when referred to the entire fruit. For equal weights, stone-fruits appear to be very much less exhaustive upon the ingredient phosphoric acid than do nuts.

Nitrogen.—Again, the Almond leads with 16.4 lb., not nearly approached by the Walnut, with 10.2 lb., or the Chestnut with 8 lb. of nitrogen withdrawn per 1000 lb. of fresh hulled nuts. These figures, while materially altered by referring them to the entire fruit, are still very high, and indicate a great draft upon the soil—several times more than the Plum or Apricot.

As nuts carry away so large an amount of nitrogen, this constituent must necessarily be replaced in the soil if paying crops of fruit are to be continuously produced.

Thus, it appears that when nut orchards need fertilisers, the first call will ordinarily be for those manures rich in nitrogen. The need for phosphoric acid will probably not be felt so soon in a Nut-orchard as it would be in an orchard devoted to stone-fruits.

Chestnuts do not withdraw so much potash and phosphoric acid from the soil as do the other nuts; but they seem to demand that the soil shall contain sulphates, which are found in surprising quantities in the kernel of the nut.

FOOD VALUE OF NUTS.

All authorities agree upon the fact that Nuts are a highly concentrated form of food. Walnuts and Almonds possess a higher nutritive value than even the cereal grains; and, as compared with fruits, they rank high in food value, being a true seed only, and not made up of fleshy coverings, as the Apple, Pear, &c; they therefore have less water and a higher nutritive value generally, weight for weight.

Where, in a rational dietary system, other forms of food lack protein or albuminoids and fat, the Walnut and the Almond will supply, in concentrated shape, those needs; the Chestnut, with its high content of starch, sugar, dextrin, &c., may, on the other hand, be used as a substitute for the cereal grains or Potatoes.

Increased production will doubtless remove the obstacle of high cost of Nuts to the consumer; and in time, if demand arises, may bring the Chestnut at least into the list of staple foods for the human family. *J. J. Willis, Harpenden.*

ORCHID NOTES AND GLEANINGS.

PHALÆNOPSIS VIOLACEA ALBA.

THIS extremely rare albino of *P. violacea* is now in flower in Lord Rothschild's garden at Tring Park. The sepals and petals of this plant have not the slightest trace of the violet-purple hue of the typical form, but are of a clear French white. The side lobe and crest of the lip are tinged with yellow, and the whole flower has a semi-transparent, waxy appearance, rendering it very attractive apart from its interest as a rare plant. *J. O'B.*

THE ROSARY.

POTTED ROSES FOR FORCING.

ALTHOUGH not so suitable for turning out into beds, or for continuous glass-house culture as some of the Teas and Noisettes, many of them are much valued for their fragrance, and for colours that are great contrasts to the soft shades of the Teas, such as Catherine Mermet, Niphetos, Perle des Jardins, G. Nabonnand, and others in pots. By cultivating the H.P.'s in pots, it is an easy matter to move them to some sheltered spot in the open as soon as the plants pass out of bloom; for, although named perpetuals, very few afford a second bloom to merit their being retained afterwards. Moreover, by that time more space is being required for the free-blooming Teas and Noisettes; these in their turn being followed by the Roses in sheltered spots in the open, whose flowers are of better quality than late blooms from pot-plants would be.

The plants already established in pots in the open ground ready for potting may now be taken in hand, and with as little delay as may be. The established plants should be removed to a cold pit or frame for a short time, as exposure to heavy rain or frost is better avoided, and the slight protection afforded will soon be needed if the wood is to be retained in a suitable condition for early forcing, the plant not responding in a satisfactory manner after it has been exposed to frost. The holes in the bottom of the pots should be cleared of soil, worm-casts, &c., and if this cannot be done, the plants should be turned out, and the crocks put in proper order, returning the ball without further disturbance, beyond taking off the surface soil. This should be replaced with sound loam, made firm with a rammer, afterwards affording a rich mulch or a sprinkle of some artificial manure or Peruvian guano, decayed dovecote dung,

or blood-manure, over which a little fresh be spread to give the plants a neat appearance.

A few of the best matured plants may at the same time, doing this a little closer than you would for the same variety if in the open border. The strongest growers require too much space for pot-work to gardeners, as they must have the whole of the wood left almost intact to obtain plenty. Rather than these I would recommend Jacqueminot, Fisher Holmes, A. K. Willtave Piganeau, and Captain Hayward for pots. Nor would I grow even these except beautiful colours, avoiding such as Gabriel Magna Charta, Baroness Rothschild, &c. much the same light shade, in better form more fragrance in the Teas, and which will treble the quantity of bloom.

So long as H.P.'s are grown on steadily early stages, they are no more difficult to the majority of other hardy-flowering shrubs the unnaturally hasty excitement of top-growth does so much harm to this section of Roses.

After pruning, stand the plants in the pot for a month or longer, keeping them close; eyes are prominent, when they may be removed to the greenhouse having a temperature of 50° to 55° should be maintained until they are fit to grow, when a rise of from 5° to 10° to the state of the weather, will be beneficial at this point a liberal use of weak liquid-manure assist the plants. From the very first appearance be kept severely in check, and an occasional water upon bright mornings will maintain atmosphere in the house. The water for purposes should contain a small quantity of tobacco-juice. When drops of moisture on the edges of the leaves in the morning, that the conditions are right, but these do not remain too long. As the season advances well to dump down early in the morning induce a rather moist atmosphere, and obtained from liquid manures, the ammonia therein maintains the foliage in health.

When starting a batch of Roses for choice plants that have been worked low roots of stocks, and which have a bushy habit should be lifted very carefully, so that the roots are lost. In potting, strong turfy loam be used, but failing that, leaf-soil, loam, and vegetable refuse and manure, with a little sand, will do almost as well if it be not too careful to pot firmly. Let the collar of the plant be buried an inch or so, and use comparative pots, but do not unduly cramp the root future potting, a richer compost may be used, plunge the pots in a frame or pit, and as the wood is sprinkled sufficiently to prevent the plants with the plumpest shoots may in February or March, but it is better if the plants are grown on steadily the first summer, and for the ensuing winter. As a general rule, turned from the flower-house into the cold frame suddenly when flowering is over, but it is a gradual hardening should take place before done. *A. P.*

VICTORIA REGIA.

FOR a long time after its introduction, but one form of this noble Water Lily. However, different varieties have made their appearance, and one of these we figure in our present issue. It has been flowering freely all the season and is remarkable for the deep, straight, not to the leaves, whilst the deeply-coloured flowers are much less spiny than in the ordinary variety. I presume it is the variety *Randi* of our friends, and it is figured, with others, in Tricker's *Water Garden*, a book we hope to notice in these columns. Some of the plants, will bear a lower temperature than others. Our illustration (fig. 81) is from a photograph by Mr. Gregory, in the Royal Gardens, Kew.

"NITRAGIN."

THE extent to which even the larger animals are dependent on insignificant creatures that can only be distinguished under the high powers of the microscope is hard to realise. The longer we live the more we find out that many of these tiny organisms, far from being the harmful parasites they were once thought to be, are absolutely essential to the lives of their hosts. In our own blood are numerous small animals, called white corpuscles, that resemble in everything but size the animals known as *Amœbæ* that live in pond-water. These white corpuscles, except that they cannot get out of our blood or live anywhere else, are as independent as we are. In diseases the destructive bacteria do not seem to be able to work alone in many cases, but require the assistance of other bacteria to prepare the ground for them, as it were. One of the most remarkable

that leguminous plants (Peas, Beans, &c.), had the power of making use of the free nitrogen of the air, and that the nodules on the rootlets were the channels through which the nitrogen was secured. Further investigation brought to light a very complicated and interesting state of affairs in these rootlets. In a thimbleful of soil there are many millions of tiny organisms, with which the root-hairs of the plant come into close contact. These organisms—or, rather, some of them—invade the substance of the root-hairs, and stimulate the tissues to form overgrown cells, which make up the nodules we have spoken of above. As fast as the cells are formed, they are occupied by quantities of organisms, which do not injure the cells, but seem to stimulate them to intense action. The result of all this is that, in a manner we do not yet understand, nitrogen is absorbed from the air in considerable amount. When the plant finds in the soil sufficient nitrogenous food

is similar, but all three arms are branched at the ends. The form peculiar to Broom is that of a well-formed comma, that of Gorse resembles a badly-formed comma, and the organism of Lucerne reminds us of a note of exclamation.

Our German friends, with their usual energy and acuteness in matters scientific, have actually begun to cultivate these organisms, and the great chemical firm of Meister, Lucius & Brünig are offering them for sale commercially. They have chosen for them the unfortunate name of "nitragin," which is certain to be confused with "nitrogen" in this country. In Germany it does not matter, as their name for nitrogen is "stickstoff." Varieties suitable for the common Pea and Field-Pea; for Vetches and Horse-Beans; for white, yellow, and blue Lupines; for red, white, and crimson Clover, Alsyke, Trefoil, Cow-grass, and Lucerne; for Sainfoin, and many others, are there cultivated.

FIG. 81.—NEW VICTORIA REGIA IN WATER-LILY HOUSE, KEW. (SEE P. 264.)

instances of this mutual dependence between higher and lower orders of beings lies in the vegetable world, and is concerned with the way certain families of plants obtain a portion of their food. The existence of the organisms that play a part in this particular co-operative arrangement is perhaps the most important discovery that has been made for many years, and should be of immense interest to agriculturists and others—all others.

For a long time botanists have been puzzled by the outgrowths or nodules that occur on the rootlets of plants belonging to the Bean and Pea family. Another curious thing about these plants is that to grow a crop of Peas, Beans, or Tares, is as good for the land as a strong dose of manure, and many farmers, especially on the Continent, have adopted the routine of growing such a crop previous to sowing the land with Wheat or other grain. The benefit obtained by doing so was obvious, although the reason was not known. Within the last few years it has been found

(nitrates, ammonium sulphate, or farmyard manure) to supply its needs, the nodules, although they are still formed, do not take nitrogen from the air, so that the organisms must have some other business besides supplying the plant with nitrogen.

By cultivation in gelatine and selection, it has been found possible to isolate the particular organisms that take part in this curious root-growth. It is found that each plant has its own organism, and in the interesting lecture of Dr. J. A. Voelcker, at the Society of Chemical Industry, a short while since, illustrations and micro-photographs of these organisms were shown. Red and white Clover and other trifoliums patronise eight different forms, although it is possible that these only represent different stages in the growth of the same organism, the final shape being a three-pointed star. The form peculiar to the Broad Bean is very similar to the last, but two of the arms are branched again. The Vetch prefers a smaller organism than the two preceding; the shape

A large number of experiments were carried out with these materials in England last year, and Dr. Voelcker gives an interesting summary of the results in his paper. Unfortunately the season was so abnormally dry that the experiments were not very conclusive, but the results on the whole were favourable. On the land of Mr. Howard Ryland, Green Peas, Broad Beans, and Sweet Peas (especially the last), benefited by the inoculation; French Beans were doubtful. At Messrs. Sutton & Sons' nearly the whole of the experiments gave favourable indications, especially as regards root-growth. Wheat is being grown this year at Messrs. the ground used for these experiments interesting to see what improvements effected.

By the light of present experiments to take the following inoculating material inoculated before

inoculated, and the organisms sown with the seed. This is important, as the nodules are formed in the early stages of the growth of the plant. As the inoculation only assists the plant to obtain the nitrogenous portion of its food, other manures, such as phosphates and potash, must be supplied, just as in the ordinary way. Where a particular crop—say of Beans—is doing well, it is foolish to expect to improve matters still more by introducing the new material, as it is quite clear that the soil is already inoculated. Further and more elaborate experiments with “nitragin” are being conducted this year, and we hope they will lead to definite rules of conduct being laid down.

One of the most hopeful applications of the new inoculating material is in connection with “Clover sickness.” It is found in practice that Clover can only be grown for a comparatively short time on a particular piece of land; the soil then becomes “Clover-sick,” and about eight years must elapse before the field can be sown again with Clover successfully. The reason for this is unknown, but it may be due to the exhaustion of the organisms that live on the roots, without which the plant cannot thrive. If this be the case, the application of fresh inoculating material will enable the farmer to grow Clover every year, if he desires it, off the same plot.

The knowledge of these organisms throws a light on the fact that, as every gardener knows, manure alone, however well-proportioned, is not sufficient for the satisfactory growth of most plants; it is necessary to have a large quantity of decayed vegetable-matter present as well. An old garden that has been well looked after produces far better crops than one newly planted, the difference being due in all probability to the quantity of these useful organisms present in the old vegetable soil.

Important as the discovery of root-organisms may, and probably will, be to agriculture, the application seems small compared to the immense possibilities that are opened up in the region of chemical industry. On the one hand, we have this inert nitrogen of the air, that can only be made to combine with other elements under the stress of the greatest force at the command of chemistry and physics, viz., the electric arc; on the other hand, these tiny organisms are making nitrogen enter into combination at the ordinary temperature of the soil. When the secret of these organisms has been mastered, we shall have drawn much closer to the boundary that separates gods and men. *C. F. Townsend, F.C.S., in “Knowledge,” September 1, 1897.*

THE HERBACEOUS BORDER.

TRITOMA SULPHURATA.

On visiting Mr. Prichard's nursery at Christchurch the other day I noticed, amongst other fine things, the new yellow *Tritoma sulphurata*. The colour of the flower is a pleasing sulphur-yellow; the flower-stems are from 1½ to 2 feet high, and for the size of the plants they are freely produced. It struck one as being pretty, and very suitable as a margin to some of the taller-growing *Tritomas*. *J. Baxter.*

AMERICAN NOTES.

AMERICAN POMOLOGICAL SOCIETY.

THIS old and dignified Association held its twenty-fifth session at Columbus, Ohio, September 1 and 2. The attendance was not very large, but a good programme was carried out, and those present generally enjoyed the meeting. Subjects which received special consideration were the importations of foreign varieties of fruits, the San José scale, spraying, and new fruits. The old and honoured President of the Society, Mr. Prosper J. Berckmans of Georgia, declined re-election. He had held the office for ten years, during which time he had gained a wide reputation as a wise student of horticulture, and is

an enterprising nurseryman. His successor, Mr. C. L. Watrows of Des Moines, Iowa, is also a nurseryman of repute, and a pomologist of ability. The old and respected secretary, Mr. George C. Brackett, was succeeded by Mr. William A. Taylor of the National Department of Agriculture. It is safe to prophecy that this selection will prove eminently agreeable to a wide circle of American pomologists. Mr. Taylor's very marked accomplishments in pomology, and his exceptionally wide acquaintance with professional and amateur fruit-growers in America and Europe, give great promise for his usefulness in the secretaryship of the American Pomological Society. We may hope, reasonably perhaps, that the Society may hereupon achieve a stronger hold on American horticulturists; for while it has been in no sense a closed corporation, and while its leading men have always sought the public good, the Society has for some reason not very apparent failed to attract a large and representative membership. It has thus not exercised the widest possible influence, and its acts have not had quite the cogency which might be desired. America, without question, ought to have a strong representative and authoritative pomological society, and there is no insuperable reason why the present organisation may not develop into a fairly satisfactory fulfilment of the ideal.

JAPANESE PLUMS.

A very marked interest has been taken in the Japanese Plums from their first introduction into America. This interest has not at all been confined to amateurs and experimenters, but market growers have planted extensively of almost all the earlier varieties. We are just now now beginning to be able to measure the value of these Plums by the market standards. Most of the varieties make good, healthy, strong-growing trees, and bear at a satisfactorily early age. The fruit of some varieties is large, fine-looking, and of good quality. They are mostly very prolific, and the fruit ships well. Some varieties are desirable on account of extreme earliness. Most of them unfortunately are cling-stones. Abundance is most widely known; but Burbank, in spite of a very ill-shaped tree, is the commonest favourite for size and quality of fruit. The nomenclature of the Japanese Plums is sadly confused, notwithstanding their very recent introduction and the earnest efforts of Bailey, Taylor, Price and others, to extricate the leading varieties. *P. A. Waugh.*

FOREIGN CORRESPONDENCE.

ABERIA CAFFRA.

THE Kei-apple of South Africa has ripened fruit this month in the garden of Mr. C. H. Shinn, at Niles, Alameda, co. California. Mr. Shinn reports that abundance of fruit “set,” but that only about eight or ten near the centre of the bush came to maturity. As far as I am aware, this is the first time this shrub has ripened fruit in California. No seeds were found in the fruits. *J. Burt Davy, Berkeley, California, September 16.*

ALDENHAM HOUSE, ELSTREE.

THE great feature in Lord Aldenham's extensive and beautiful gardens is the ornamental water which runs through the greater part of them, sometimes as a narrow rivulet, with neat grassy banks or rocky edge, here and there broadening into a greater expanse, which in the new water-garden, formed on the site of the moat of the old hall, is of considerable extent, and everywhere beautified by the skilful manner in which Mr. Beckett, the gardener, has arranged the clumps of flowering and foliage shrubs, the masses of showy, hardy perennials; and in the water, the Water Lilies and other water plants. Even the stone bridges which span the ornamental water are made to contribute their share of flowers by the interstices in the stones, and

the sides of the rocky basements being planted with Saxifragas, Sedums, and other close-growing alpine plants, among which the clumps of *Gentiana* have been giving a fine show of rich dark blue flowers, and other dwarf-growing species usually seen but small tufts, have here grown into masses 3 or 4 feet across, and flowered profusely. Glancing along the banks, the effect of the skilful use of coloured foliage shrubs is very evident at this season, when their colours are more noticeable even than in the summer, when bright-coloured flowers are more plentiful. Of the coloured-leaved shrubs, the golden-leaved *Poplar*, which is here cut back every year, is very bright and effective; very telling, too, are the clumps of *Golden Privet*, which are also restricted in growth according to the position it occupies. The *Copper Beech* is made to assume a pyramid or bush-form, and its dark tints are very effective; so also the *Prunus Pissardi*, *Golden Yews*, clumps of variegated *Cornus*, and great number of other coloured foliage. But in every instance where one of these is used, sufficient of it is planted together to give the desired effect, and the same object does not occur beyond the scope allowed to it until another view is opened up. This plan of planting in masses of one thing, with an edging of dwarf *Privet*, *Hypericum*, *Vinca*, or similar plant, is adhered to throughout, and mixed shrub-beries are avoided as much as possible. By this means the feeling that any portion of the outdoor garden is a sample of the whole, which prevails in a garden where mixed planting is the rule, is done away with, and some beautiful and striking effect secured, which last in the mind. As, for example, the great masses of white and red-flowered *Rosa rugosa* at Aldenham, whose waning flowers are mingled with a profusion of orange and scarlet fruit, the great beds of *Hydrangea paniculata*, and large masses of other showy things, which are calculated to leave an impression on the beholder not possible were the plants set out in mixed beds.

Of berried plants, *Crataegus pyracantha* is the most brilliant, a good portion of the mansion on one side being covered with its branches, closely set with scarlet berries. In the grounds, and along the banks of the stream, too, this plant is grown in dwarf pyramids, also covered with berries, and so used it is one of the best and brightest things of its kind. The different species of *Crataegus* are also bright with coloured fruits; and among the *Cotoneasters*, *C. Roylei* as standards bearing pendulous branches of round leaves and purple berries, are pretty and uncommon objects. Along the banks of the stream, and in other parts of the garden, there is still a good show of flowers, both annual and perennial. The glowing yellow of the *Sunflowers*, the bright and varied colours of the *Dahlias*, *Gladioli*, and other tall growers rise behind the rich orange clumps of *Montbretias*; the crimson, white, and purple of the *Pentstemons*; the tall spikes of scarlet *Lobelia cardinalis* *Queen Victoria*, which in one place is mingled effectively with the blue *Salvia patens*; the bright mauve tints of the *Asters* of the *Michaelmas Daisy* class, of which there is a very great number of varieties, one great bed containing some hundreds of plants, soon to be masses of purple, mauve and white flowers; bushes of *Fuchsia Riccartonii*, trained pyramids of *Eccremocarpus scaber*, which like *Mina lobata* and *Maurandya Barclayana*, makes very effective specimens when so managed. Around the mansion, the oblong carpet-beds, alternating with circular beds of *Fuchsias*, are still bright and trimly kept. In the bedding-plant arrangement the tuberous *Begonias* certainly have the advantage, for they are covered with rich crimson flowers; and the large bank of sub-tropical plants seems even more massive than formerly, probably on account of many of the plants having attained such vigour before being planted out. For a view of the flower-garden see *Gardeners' Chronicle*, March 7, 1897, p. 297.

In the wild garden, the walks of which are made as for gravel paths, but turfed over so as to be clean in all weathers, are many subjects which have assumed unusual beauty, by being allowed to grow unrestricted. Of these, very striking are the large patches of double-flowered *Bramble*, now covered with

clusters of small rose-like blooms; the cut-leaved Brambles, handsome both in leaf and fruit; the Hydrangeas, Heaths, Climbing Roses, of which the Crimson Rambler is the favourite; and numbers of other things capable of taking care of themselves, and mingling effectively with the bracken and tall grasses growing beneath the stately Oaks and other large trees, which so greatly beautify this large and beautiful estate.

THE GLASS-HOUSES

are devoted principally to the growth of fruit, and flowers for cutting, and plants for decoration. The long ranges of vineries and Peach-houses have heavily cropped this season, the quality of the fruits being of the usual excellence for which Mr. Beckett is noted, and of which beholders of his prize-winning exhibits at the large shows has, as in former years, had evidence. The Crotons and Dracenas have very brightly-coloured foliage; the Calanthes, Cologynas, and Cyrtopodiums promise well for bloom; and the immense number of Chrysanthemums, for which Aldenham is noted, are in splendid condition.

The kitchen garden, with its cross-walks of showy herbaceous perennials, is as neat and well-kept as every other part of the garden, and good results in everything have been obtained, though it is said with more than usual labour on account of the peculiar season, which has also caused the crops of out-door fruits to be very far below the average; Plums, of the larger fruits, being the best. *J. O'B.*

THE COPPER TREATMENT OF THE POTATO DISEASE BY THE BORDEAUX MIXTURE.

THE *Gardeners' Chronicle* was the first journal in which this method of preventing the ravages of the Potato disease was explained to the English-speaking world; many and frequent are the allusions which have since been made to it in these columns. At first, because the Mixture was not properly made it was opposed on the ground of injury to the Potato foliage; but it was soon found that with a little more time and a little more care, no injury was done to the plant. That the method has not been more widely adopted is simply because we have for a series of years been exempt from the disease to a greater or less degree. This year, however, we are hit, and our neighbours across the Channel even more so, and the matter of course assumes a political phase. In one of our leading daily papers, an article appeared recently headed, "Is it famine?" in which a pitiful account was given by an eye witness of the state of the Potato crop. He says, moreover, "the only Potatoes good for anything are those which were 'sprayed' twice." This shows clearly enough what an eye witness thinks of spraying. But the writer goes on to show that it is practically useless to the very small grower on account of the expense—mainly the cost of hire, for purchase is out of the question—of proper spraying machines by the very small and very poor growers. We do not doubt that the inhabitants of Ireland are poor, but we venture to think that where there is a will there is a way. From France the Bordeaux Mixture came; and from France, it seems, we must learn that poverty is no bar to its successful use. A visit to Paris and neighbourhood soon showed us that sacksful of sulphate of copper were disposed for sale in the county towns—so that there must be some demand for it. We find, as we expected, that the French peasant does not mean to lose his crop if he can help it. He often unites with his neighbours, and forms a syndicate in a small way for the purchase of a spraying-machine. But if he is too small a grower, and too poor even for this, does he stand still with his hands in his pockets lamenting over the loss of his Potatoes? Not a bit. He takes a bundle of Heather or Ling, makes it into a little broom, and slings the remedy by hand over his patch of Potatoes. Are the Potato plots in Ireland too small for this?—is Heather too expensive?—or can it be possible that it is too much trouble? *William B. Plowright, M.D., King's Lynn.*

STOCKHOLM.

THE AUTUMNAL FRUIT SHOW.

ABOUT the same time as you held your great show of British-grown fruit, Scandinavian gardeners and nurserymen also exhibited their products at a show here in Stockholm. It lasted from September 23 to 30, and was the most successful show of the kind ever held in this country. The four northern countries, Sweden, Denmark, Norway, and Finland were all represented. For plant-growing, of course, Denmark is climatically the best favoured, and Danish nurserymen are more experienced exhibitors, and it must be admitted that their display was the best in quality and arrangement. Two Norwegian nurserymen also showed some excellently-grown plants. But the Swedish growers seemed to compete very well, and would have done better if the arrangement had been better carried out. Ferns, Palms, Dracenas, Pandanus, Crotons, Ficus, Philodendrons, Asparagus, Myrsiphyllum, and other decorative plants were well represented. Some early Chrysanthemums and some good collections of Cactus Dahlias were also shown.

As to decorative flower arrangements, there were some capital exhibits, and the firm, R. Billström, Stockholm, made really a grand show. There were Orchids, different coloured Nymphs, and many other rare flowers in this country in great profusion and excellently arranged.

In the vegetable department some Norwegian nurserymen made the best show of Cucumbers and Melons; and from the north of Sweden were shown some really high-class vegetables. Globe Artichokes could not be seen better than at this show. Tomatoes are beginning to come into fashion in this country, to judge by the numerous exhibits of this fruit. Finland made a good show of vegetables. Several exhibits came from far north of the polar circle!

The fruit-show was really grand, and was, as far as Sweden is concerned, the chief part of the show. As to the mode of arrangement, there were collective shows from the different counties, and separate shows from many great fruit-growers. In many of the counties shows had been previously held for the purpose of selecting the exhibits. It was astonishing, even to many in this country, to find what a great variety of good fruits can be grown so far north. Some exhibitors from the southern counties, I think, could have competed favourably anywhere. Of course, many of the finest foreign varieties of Apples and Pears cannot, to any extent, be grown in this country; but some of our natural varieties are of a high-class quality. It is easy to understand that, for those kinds of fruit that can stand our hard winters, and do not want too long a time for their development, our fine summers, with their long days and bright nights, are highly favourable for giving high colour and good flavour.

As regards the development of fruit-growing in this country, it is going in the same direction as in other countries. A great number of varieties are tried, but growers are gradually fixing upon a small number for cultivation on a large scale. Dwarf-growing trees are more and more taking the place of tall-growing standards, because they are easier to protect, and the fruit is of a higher quality. What is sorely wanted here, as in many other places, is a better system of sorting, packing, and marketing the fruit. *A. H. M., 31, St. Nygatan, Stockholm, Oct. 3, 1897.*

FORESTRY.

TYPES OF BRITISH WOODLAND.

AN easy and usually effective method of altering the character of a wood on flat ground is that of leaving patches of bad or boggy ground unplanted, and allowing them to grow whatever may chance to take root on them. Such patches let light and air into the wood, and the trees round their margins are well clothed with branches, and may, if desired, be broken up into groups, or single trees may be isolated

to relieve the general appearance of the outline. Such patches as these are of great value to the sportsman, as they furnish plenty of grass and low growth for game cover, and being warm and sunny, both ground and feathered game make them favourite resorts. Another means of affording variety is by introducing patches of underwood here and there throughout the wood, either in the shape of ordinary coppice, or by planting low-growing or shrubby species in place of the ordinary timber-trees. Patches of Gorse, Broom, or even Heather all help to enliven and change the scene where necessary, and allow what ground is really under timber to be treated independently of game or ornament.

Another feature of mixed or woods of any kind consists in the general appearance presented from the rides which intersect them, and the manner in which these latter are laid out. Rides are ostensibly formed to facilitate the removal of timber, and to allow sportsmen and others to penetrate into all parts of the wood without difficulty. But when judiciously planned, they also enable the most picturesque parts of a wood to be seen without leaving the beaten track. Their course is often determined by the conformation of the surface, and in such cases little pains need be taken beyond those necessary to ensure a suitable gradient for the hills, and the avoidance of difficult obstacles. On flat ground the question is rather how to give them a certain amount of intricacy without taking unnecessary curves and turns.

The usual course is to run a ride round the margin of the wood at a short distance from the boundary line, and into which those from the interior run. This idea is a very good one, but is sometimes spoiled by following too faithfully the exact line of the boundary at too regular and short a distance from it. When so formed, the exterior of the wood becomes visible as the trees get thin below, and the view from the ride is neither one thing nor the other. It is better to allow it to run right up to the margin in one place, and recede well back from it in another. By this means the scene is occasionally enlivened by the more extensive view presented to the eye, and at the same time the idea of unbounded extent is more effectually imparted than in the former case. The axiom sometimes heard, that "Nature abhors a straight line," applies with more truth to woodland rides than to roads in general. For convenience when shooting, it is not uncommon to find rides laid out perfectly straight for a considerable distance, and one or two of this kind in a large road may not be altogether out of place. But in a general way, the idea a woodland ride should convey is that of it having been cut or made through the trees, and not that the ride was first formed and the trees planted afterwards. A straight ride never conveys the former of these ideas, unless it is narrow enough to pass between trees 2 or 3 feet apart; but if made with a light curve at one or two points where a clump of trees in close order, or a single tree of large size, are to be found, the result is much more natural and pleasing. The width of the ride is not without importance also. When wider than 10 or 12 feet, it fails to lend itself to the idea of being a roadway through the plantation, and becomes a sort of attenuated clearing not wide enough to call a glade, and too broad to be styled a track. When breadth is necessary in a ride for sporting purposes, a condition only really necessary in young plantations, it should be attained at a few places only, and the trees allowed to stand close up to the used track as much as possible.

The density of young plantations, which often renders them so monotonous at first, is never relieved by widening the rides running through them, as many seem to think. It is rather effected by making short openings a few yards into the wood, which terminate in small partial or total clearings, the margins of which are visible from the ride. By such means, the effect of sunlight falling on or through the foliage, when the observer himself is in shade, can be best seen and appreciated. As the trees get older and thin at the bottom, the

beneath becomes more extensive; and these occasional openings, by retaining some of those features common to partially-isolated trees, are still useful in giving variety to the wood. *A. C. Forbes.*

(To be continued.)

BOOK NOTICE.

THE PRINCIPLES OF FRUIT-GROWING. L. H. Bailey.

THIS is one of the best of modern books on the cultivation of fruits which has come under my notice, and possibly somewhat too technical for those who have a distaste for elaborate columns of figures and statistics. The book, however, contains an immense fund of sound, useful information, which ought to be read and put into practice by every aspiring cultivator of fruits in this country. It betokens throughout an honest endeavour to unite the teachings of science with knowledge gained by long years of experience. If one would read it unbiased and unprejudiced, matters of much importance may be discovered between the lines that relate to the success of the orchardists on the other side of the Atlantic. This should at the least be worth some amount of consideration, for it is clear to everybody that our home fruit-growers are being beaten in our own markets with fruits which we are quite competent to produce "if" we could only learn better methods of cultivating, &c. This has been demonstrated over and over again. The fact is, our fruit farmers have much to unlearn—an unpleasant fact; but the author explains to us how this has likewise to be done in America, for he says, "Very many of our best fruit-farmers are men who were not brought up entirely on the farm, but who had received a sound business training elsewhere. They come into the business with trained minds, skilled judgment, and especially without too much stereotyped knowledge, and therefore without prejudice. They are willing to learn, and they quickly assimilate new ideas. It sometimes seems as if the fruit-farmers of the future are to come largely from other occupations, where men are free from the bonds of tradition."

Separate chapters are devoted to such subjects as soils, situations, aspects, wind-breaks, shelter, frost, drainage, climate and others, all of which are ably dealt with. Insect-pests also receive full attention. Information of great interest is fully supplied upon a subject little thought of by the ordinary grower, viz., the evaporation that goes on from the twigs during dry frosts, when the sap supply is stopped through the action of frost; hence the shrivelled appearance of the bark, especially in newly-planted trees.

The benefits and injuries due to mulching also receive explanation. On the other hand, it is new to us Britishers to be told that "A thorough spraying of plants at nightfall, when a frost is feared, is one of the most efficient means of protection from light frosts." . . . "An abundance of watery-vapour in the air probably tends to check the radiation of the earth's heat, and the evaporation of water has a pronounced influence in raising the dew point."

Rightly or wrongly, it is the custom of the ordinary English gardener to prevent his wall-trees from getting wet by rain or sleet showers during this critical period.

The kindling of fire-smoulders in the orchards, to cause a dense smoke, is also recommended as a frost-protector, for the author says, "Every quart of water thus evaporated, and again condensed in the surrounding air, would be sufficient to raise the temperature 10° throughout a space 80 feet square and deep."

We do not agree with the author's statement in regard to the tillage of young orchards, for he says—"In young orchards it is commonly best to 'plow' rather deep, say 6 or 8 inches, in order to send the roots down," seeing that it is always our greatest endeavour to keep the roots of bushes, wall-trees, &c., as near the surface as possible. We are reminded

that trees may be made to grow too much wood, and therefore too little fruit certainly, but this 6 or 8-inch ploughing assuredly aggravates the evil. This applies more particularly to the States, where extremes of heat and cold are greater than here.

Plant-foods furnish some astonishing statistics, for it is stated that, in round numbers, 5 bushels of Apples, with the leaves of a tree large enough to produce that quantity of Apples, assimilate 21 lb. nitrogen, 3 lb. phosphoric acid, and 26 lb. potash, from the soil; but it should in justice be stated that the author shows how much of the above fertilisers are restored to the earth by good tillage and cultivation.

He also affirms "that of these means of determining the fertility of the land, one method determines the physical constitution, and the other the mechanical or physical condition; chemistry determines the amount and kind of plant-food in the soil but it cannot tell just how useful this food may be to the plant. This depends upon the physical condition of the land, or upon the relation of the soil to warmth, moisture, air and mechanical constitution. The only infallible guide to the proper treatment of the soil is experience, not mere science or speculation; but science explains the laws and directs the application of them when once experience has discovered them. Fruit farming cannot be done by recipe."

Some excellent advice is given in the matter of selecting young trees, and the author goes on to say:—"The nurseryman contends that he grows the varieties which the planter wants, those for which there is a demand. As a matter of fact, he largely forces the demand by magnifying the value of those varieties which are good growers in the nursery. The nurseryman's business ends with the growing of the young tree, and the tree which makes the straightest, most rapid, and cleanest growth, is the one which finds the readiest sale. Now it by no means follows that the variety which is the cheapest and best for the nurseryman to grow is the best for the fruit-grower, the fact being often overlooked that fruit trees are just as distinct and different in habit of growth as they are in kind of fruit." It being plainly demonstrated that a thorough knowledge of these matters, and the putting of the same into operation, is quite as essential and important as pruning, planting, &c.

Information on grading, packing and marketing is also given in detail, and of a concise and practical character, which every home fruit-grower may profit by.

The price of the work is 5s., a very moderate charge for so much useful information, and which we can conscientiously recommend. *W. C., The Macmillan Co. New York; and Macmillan & Co. Limited, London.*

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Laying Late Broccoli.—Late Broccoli growing in the rich soil of a kitchen garden have made a rank soft growth, and they are sure to succumb if the frosts are severe. To ensure greater safety to the crop, the plants should be heeled-in with their heads towards the north. There are gardeners who will not take this precaution, believing it to be useless; and in the warmer southern and western maritime counties it may not be necessary, but a short experience of a locality will soon determine what course he should take. My experience at nearly 600 feet above the sea-level is that Broccoli cannot withstand the frosts of an ordinary winter, although it is a southern maritime county. Heeling-in is a simple job, taking but little time to perform, but that it pays for the doing I have repeatedly proved. For the benefit of those who may not have heeled-in any Broccoli, I will briefly describe the process. Supposing the rows to run N. by S., take out a spadeful of soil on the north side of the first plant, of course starting at the N. end of a row or plantation, then putting the spade a good distance under the plant tilt it over backwards till it is laid nearly flat, and take a spadeful

of soil from behind the next plant and place over the stem of the one first laid, and so on with every one in a row. The plants may flag slightly for a day or two if the weather be dry, but this is an advantage rather than otherwise; and it will not, if the operation has been carefully performed, affect the well-being of the plants.

Early Varieties of Broccoli and Late Ones of Cauliflower.—The beds of these plants should be examined once or twice a week, and the leaves broken down over curds as a means of protection against the light, frost, and rain. The largest heads may be stored roots and all, in a cool shed where they will keep fresh for a week or longer time. Frigi domo, or thick cotton shading, may also be used to ward off frost for the few nights that autumnal frosts last.

Lifting and Storing Roots.—Beetroot and Carrots are among the first roots to lift and put into store, and the first-named is more tender than the second. The roots keep well in a cool, well-ventilated cellar or thatched shed, and the cooler the better. Lift the roots without breaking the tap-root, and having done that, seize the leaves in a bunch, and twist them off above the crown, and then pack the roots together in damp sand or soil, the crowns pointing to the outside, and, if possible, to the light. If for lack of accommodation Beetroot have to be stacked, plant in a border thickly in a sheltered border, the open, the crowns must be protected by bracken or litter, in the case of a stack, by thatching it. Carrots may be stored in the same way, but in the case of these roots, the tops should be cut close to the crown, and the roots like Potatoes, enough being reserved for a few weeks' supply, as it might not be convenient to open the store-pits during severe frost or heavy snowfall. Parsnips have the best flavour and quality when left in the ground and taken up as required, affording the ground a covering of litter to keep out frost.

Salsify and Scorzonera may be lifted and stored in the same manner as Beetroot, cutting off the tops, but not breaking the smaller roots. Only the best roots of any kind should be stored; malformed and those with divided roots being reserved for present use, or given to the pigs or cows if the crops are sufficiently good.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leicestershire.

Cucumber Plants.—The winter-fruited plants should be making bine rapidly, if they were planted about the beginning of last month; and later plantings will be making satisfactory progress during the present genial weather. Let the bine be thinned out somewhat, the laterals pinched at regular intervals of time, never taking away much growth at one operation, and endeavour to get the trellises well covered with sturdy foliage. If aphides, red-spider, or mildew appear, lose no time in applying a remedy, as, for example, Richards' XL All vaporizer for the insects, and flowers-of-sulphur for the mildew. As a preventive of the last pest, paint the hot-water pipes with lime-wash containing sulphur. Afford the hills slight dressings of fibrous loam as frequently as the roots show at the surface, keeping the latter friable and crumbly, and while not making the soil very moist, see that the plants do not lack water at the root, or red-spider will soon show itself. Old Cucumber plants that are still useful should have the fruits removed from the laterals for a time, so as to allow the plants to recover their vigour, future cropping being regulated with judgment, and not more than one fruit allowed to a joint, and these distributed all over the trellis. Only tepid water should be afforded Cucumber plants, and an occasional syringing at closing time on fine days will still be of benefit to them. Admit air on all favourable occasions.

Melons.—Plants with ripening and growing fruits should have useless lateral growths pinched out, and the temperature of the bed and of the air will be maintained, closing early in the afternoon, and covering the house at night. Water will be but sparingly required by plants with fruits nearly developed, and not any by those approaching the ripe state. All fruits that show signs of being almost ripe should be removed from the plants and stored in a dry place. They will keep sound for a week.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maidenhead.

American Plants.—Although it may be preferable to plant Rhododendrons, Azaleas, Andromedas, &c., in the spring, there is at that season so much important work to be done, that it is difficult to spare the

requisite labour. In many gardens, therefore, it will be more convenient to plant such subjects in early autumn, and if the work be done during the present month, the plants will succeed well enough. If the natural soil of the place is adapted to the growth of these plants, there need be little labour; but if it be of a heavy, clayey nature, or should it contain much chalk and limestone, the natural soil in the beds or borders should be thrown out to a depth of 2 feet. If necessary, artificial drainage must be provided below this depth, and the bed afterwards made up with peat broken up moderately fine, the rougher parts to be placed in the bottom; or, failing this, rather light fibrous loam and leaf-mould in equal parts, and well mixed together. The soil should be moderately dry when used, and when it has been made firm by treading, it will be in a condition to receive the plants. The plants will need to be put at distances apart according to their size, good, bushy specimens about a yard high generally requiring a similar distance between the plants. Tread the soil firmly round the plants, and give one watering should the weather continue dry. Varieties are so numerous, it is not necessary to give names of *Rhododendrons*, but a few of the early-flowering *Noëleanum* type should be included; and if they are planted somewhat in the shelter of tall deciduous trees, these will afford slight protection to the early flowers.

Roses on Walls and Fences.—If any planting has to be done, preparations should be commenced at once. Roses prefer a moderately heavy and retentive soil; but if the staple be very wet and heavy, it may be necessary to incorporate some rotten manure and wood-ashes, and to provide drainage. The opposite extreme—light sandy soil—however, is worse; and should the staple be of this nature, it must be supplemented by soil of a much heavier nature, and some rotten dung. Roses may be moved at the present time with safety, and if planted early, they will become re-established before severe weather sets in. For clothing open fences or any cold position, even a north aspect, the *Polyantha* Rose, *Turner's Crimson Rambler*, is one of the best varieties, and it also makes an admirable pillar Rose. Other good climbers include *Gloire de Dijon*, which, for colour, continual blooming, and general hardiness, is unrivalled. *Maréchal Niel* should be planted against a south wall; the old *Gloire des Rosomanes*, with semi-double deep crimson flowers, is a strong grower, and continues in bloom into the winter months; *Reve d'Or*, *Climbing Captain Christy*, *Reine Marie Henriette*, *Madame Alfred Carrière*, *W. H. Richardson*, *Cheshunt Hybrid*, and *Climbing Devoniansis* are desirable Roses for planting against walls or fences.

General Work.—Preparations may be made for re-filling the flower-beds when frost has killed the plants they now contain. If small trees of *Retinosporas* and similar subjects are used, any strong growers may be partially lifted with a fork, and the growths cut back if necessary preparatory to their removal to the flower-beds. If gravel walks are infested with weeds, the present fine weather affords a favourable opportunity for applying a weed-killer, which should keep them free for the next six months at least. Being a very strong poison, this should be used with great care, and a special can and tub be kept for using same.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Miltonias.—Plants of *Miltonia vexillaria* should now be removed from the cool house to the intermediate-house, choosing a position where they will obtain plenty of fresh air and light. Plants that were re-potted in August are now rooting freely, and if the moss on the surface of the soil has failed to grow, the dead pieces should be removed, and fresh heads of living moss carefully pricked in thickly over the surface. *M. Phalenopsis* should also be put in the Cattleya or intermediate-house at this season, also the lovely rose-scented *M. Roezlii*. The two latter species, if necessary, may be re-potted, but do not use pots of too large a size. Both species are deeper-rooting subjects than *M. vexillaria*, therefore they root and grow more freely if a few crocks only be placed over the bottom of the pot, using sphagnum-moss only for the plant to root in, excepting a few small pieces of crock. *M. Phalenopsis* delights in plenty of light, but *M. Roezlii* prefers a little shade. *M. Endressii* also prefers a shady position. The beautiful hybrid, *M. Bleuana*, and its distinct variety *nobilior*, now in full growth, should be placed in the intermediate-house. The late-flowering varieties of *M. vexillaria*, as *rubella*, *splendida*, and the rare *Leopoldi*, require to be very carefully

watered until the roots are again active. All the other varieties mentioned require abundant supplies of water until growth is completed. At this season small yellow thrips are generally troublesome to the young growths of *Miltonias*, and every effort must be made to get rid of them. Other members of the *Miltonia* family, which are quite distinct in appearance from the preceding varieties, as *M. candida*, *M. Russelliana*, *M. spectabilis*, *M. Peetersiana*, and *M. virginialis* are now in bloom, and the plants should be kept rather on the dry side until growth re-commences. The intermediate-house is the proper place for them. The rare and distinct *M. Lubbersiana* should be suspended close to the roof-glass in a shady part of the Cattleya house.

Cattleya-house.—In the last-named division several plants of the pretty *Vanda Kimballiana* are now making a pleasing show. After the spikes have been removed, little water is required at the root, as the terete leaves are liable to become discoloured if much moisture be afforded. Its allied species, *V. Amesiana*, is fast sending up its spikes, and the plant should be well watered until the flowers commence to open. Both species should be grown at the coolest and lightest part of the house. Plants of *Cologynne cristata* and its varieties may be assisted to finish up strongly by affording abundance of root moisture until the bloom-spikes appear. Keep the plants near to the roof-glass, as plenty of light at this period is indispensable. Other *Cologynnes* that are in full growth should be thoroughly watered each time the plants become dry. *Anguloa Ruckeri*, *A. Clowesii*, *A. uniflora*, and *A. eburnea* should now receive all the sunlight possible. When the leaves commence to change colour, the plants will require less water, but sufficient must be given to prevent the pseudo-bulbs from shrivelling.

In the cool-house.—The Brazilian *Oncidium varicosum*, *O. Forbesii*, and *O. crispum* are producing flower-spikes. It is very easy for these plants to over-flower themselves, and they then gradually dwindle away. To avoid this, it is good practice, even with strong, well-rooted plants, to remove the spikes as soon as the flowers are open, and as regards small weakly plants, to pinch out the spikes immediately they appear. *O. concolor* will now require less water at the root; its flowering season is in April and May. The pretty *Stenoglottis fimbriata* appears to delight in plenty of water at the root at all seasons. It should be potted in a mixture of peat and coarse silver-sand, and in a similar manner to an ordinary greenhouse plant.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton Hoe Park, Luton.

The Plant Stove.—The various plants in this house, whether about to rest or those which grow more or less during the coming season, are the better for an examination, and some of them reported or shifted, notably *Codisiums* and *Dracenas*, which it was desired to increase the stock of, and were tongued in the early part of the year with that intent, and have been cultivated in 60's. The pots into which these plants may now be put should be about one size larger. After potting let them be stood in a shady part of the house or in the stove-pit for ten days. *Allamandas* and *Dipladenias* growing in pots should now be placed in the sunniest part of the house, so as to ripen the wood ere they are pruned. *Anthuriums* should be watered with care at this season, and not allowed to become quite dry at the roots, sufficient water being given to keep the sphagnum-moss fresh and green at the surface. *Begonia corallina* is a plant which, when planted out, or grown in tubs, should now be assisted with liquid-manure. It is a handsome species, with long racemes of bright coral-red flowers of considerable length, and the latter are borne in the greatest profusion. The plant looks well when trailing along overhead-wires in the stove. The plant lasts in flower for a long time, and is readily propagated in the spring from cuttings or seed. It does not flower freely when young. The temperature of the stove may be kept at this part of the season at 65° by night, with a rise of 6° to 10° by day, according to the weather; and any syringing of the inmates that may be required should be carried on in the morning hours.

The Greenhouse Cinerarias.—The earliest raised plants are now showing flower, and may be afforded once a week applications of weak, clear soot-water, and fumigated, when the leaves are dry, for the destruction of aphides; in fact, mild fumigation should be done once in ten days whether the insects are observed or not. Grow the plants in a cool-house, and afford them plenty of ventilation, but not so

much as will cause the leaves to flag. Succession-plants will require to be shifted into larger pots; and the next to flower may be placed in the pots in which they will flower. Let these succession plants be kept in a cold-pit or frame, where they will be quite safe if protected with mats, &c., on frosty nights; and where they will have the moist, cool surroundings just suited to their needs. In such places, slugs do a good deal of harm at times, disfiguring the leaves, and these creatures must be trapped with slices of Potato, bran, &c.

Ericas.—These plants may now be placed in the greenhouse or cold pit. *Ericas* must never be allowed to get dry at the root, and when water is afforded, it should suffice to moisten the whole of the ball of soil; and rain water is the best to use. *Correa cardinalis*, and *Boronia*, should be put at the warmer end; *Acacias*, *Aphelexis*, *Pimelias*, *Tetrathecas*, and plants of a similar nature, may also go into the greenhouse. Some of the forwardest of the *Cyclamens* may now be allowed to flower, affording them a night temperature of 50°, and fumigating the house regularly for the killing of white thrips. The flowers of later batches should be removed as soon as they can be got hold of with the finger and thumb. *Cyclamen* flowers, when required for any purpose, should always be pulled, and not out, as, in the latter case, the remaining portion of the stalk decays, and it carries decay to the corm. A sowing of *East Lothian Stocks* should now be made in pans placed in a cold frame, from which frost is excluded, growing the seedlings cool during the winter.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Fruit Picking.—The weather during the present month has so far been favourable to the ingathering of Apples and Pears, and the ripening of the current season's shoots. Therefore, the harvesting of the above-mentioned fruits will be nearing completion in most fruit-growing districts, in which, however, the fruit crops are unfortunately much below the average, though individual fruits, owing to the lightness of the crops borne by the respective trees, are fine in size and good in quality, especially in the case of trees growing in heavy moisture-holding soils. As stated in previous calendars, the fruits should be carefully handled in taking them from the trees, and spreading them on the shelves in the fruit-room, blemished fruits being placed on shelves by themselves for present use.

Fruit-room.—Admit air freely when the external air is dry and as warm as that of the room, so as to admit of the moisture arising from the freshly-gathered fruits being dissipated. The fruits in store should be looked over bi-weekly, and all such as show signs of decay removed before they contaminate the sound fruits. Just now, such Pears as *Beurré d'Amanlis*, *Doyenné Boussoch*, *Pitmaston Duchess* and *Louise Bonne of Jersey* are particularly liable to decay, and should be closely inspected; and later sorts of Pears and Apples in their season.

Destroying Seedling Weeds.—The plantations of Strawberries and Cranberries should be hand-weeded, and where possible the weeds cut down with the Dutch-hoe in all parts of the bush plantations, and those of Raspberries.

Budded Fruit-stocks.—All of the recently-budded stocks of Apples, Pears, Plums, &c., should have the ties which are likely to constrict the bud by cutting into the rind severed in one place so as to afford relief. A little timely forethought exercised in this direction is rewarded by the production of uniformly better and handsomer trees, the point of union between stock and scion being scarcely visible to the non-professional eye, a circumstance which generally results in health and productiveness.

THE NURSERY AND SEED TRADE.—Mr. B. WYNN, 1, Dane's Inn, Strand, has published an alphabetical list of the nurserymen and seedsmen of Great Britain and Ireland, together with their postal and their telegraphic addresses. The plan adopted is simplicity itself, the type bold, and easily read. There are nearly 4000 entries.

PLANT PORTRAITS.

GLADIOLUS COMTE DE KERCHOVE, *Revue de l'Hort. Belge*, October 1, 1897.

APPOINTMENTS FOR THE ENSUING WEEK.

SALES.

MONDAY,	Oct. 18	Bulbs, at Protheroe & Morris' Rooms. Nursery Stock, at the Branch Nurseries, Heathfield, by Protheroe & Morris (two days). Bulbs, Plants, &c., at Stevens' Rooms.
TUESDAY,	Oct. 19	Bulbs, at Protheroe & Morris' Rooms. Lilies and Palm-seeds, at Protheroe & Morris' Rooms.
WEDNESDAY,	Oct. 20	Bulbs, at Protheroe & Morris' Rooms. Roses, Plants, Shrubs, Bulbs, &c., at Stevens' Rooms. Sale of Nursery Stock, at the Northgate Nurseries, Chichester, by H. W. Rendell.
THURSDAY,	Oct. 21	Bulbs and Palms, at Protheroe & Morris' Rooms. Orchids, Palms, &c., at The Gardens, Stowe House, Buckingham, by Protheroe & Morris. Bulbs, Plants, and Roots, at Mr. Stevens' Rooms.
FRIDAY,	Oct. 22	Bulbs, at Protheroe & Morris' Rooms. Orchids, at Protheroe & Morris' Rooms. Fruit Trees, Roses, and other Stock, at the Cart House Lane Nursery, Horsell, near Woking, by Protheroe & Morris.
SATURDAY,	Oct. 23	Bulbs, at Mr. Stevens' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—49° 5'.

ACTUAL TEMPERATURES:—

LONDON.—October 13: Max., 52°; Min., 42°.

PROVINCES.—October 13 (6 P.M.): Max., 57°, at Valentia Island; Min., 41°—44°, Scotch Coast.

The Composition of Orchids.

IN the *Comptes Rendus* for July 12, the results are given of experiments made by M. LECLERC DU

SABLON regarding the constituent parts of the tubers of hardy Orchids. The author says that: The materials stored in Orchid-tubers are principally composed of starch and a mucilaginous matter which is the same in composition and has almost the same properties as starch.

New tubers usually appear in December or January; they grow rapidly, and in the following season, in April, are of about the same size as the old ones. Then, in May or June, when the stem is dried up and the old tubers are withered, the young tubers pass into a state of latent life, and begin towards the month of September to produce a new stem. During winter and spring the tuber is gradually absorbed to form the stem and leaves, then the flowers and fruit.

There are then, in the life of an Orchid-tuber, two periods of active separated by one of latent life. The first period of active life extends from December to May—this is the period of formation; the period of latent life is from May to September, and the second period of active life commences in September and ends in the May of the following year—this is the period of destruction.

In analysing the tubers at different seasons of the year, the relation existing between the chemical composition and the state of development is seen. The substances analysed are: 1st. The reducing sugars or glucose; 2nd. The non-reducing sugars or saccharoses; 3rd. Amylaceous matters or amylose composing the starch and mucilaginous matters soluble in water and insoluble in alcohol at 90°. M. LECLERC DU SABLON did

not separate the starches from the mucilaginous matters, as all these substances play an analogous part in the nutrition of the plant. The analyses were made in almost every month during the years 1896-1897. From February to June the plants have two tubers, a young and an old one, which were, of course, analysed separately. The species which yielded the materials for study is *Ophrys aranifera*.

At each of the seasons of the year mentioned in this table, were made four or five experiments involving some twenty tubers; the results were not always identical, especially as regards the amylaceous-matters; the numbers given are those most nearly approaching the mean.

The figures in the table indicate the proportion of glucose, saccharose, and amylose yielded by 100 parts of analysed dried matter. It is shown how, during the period of the formation of the tuber, from February to June the proportion of starchy-matters is constantly increasing; the sugars, on the contrary, which are at first in considerable proportion, disappear almost wholly.

During the period of repose, corresponding nearly to the summer, the only carbo-hydrates found in the tuber are the amyloses, by which the part taken by the reserve matters is clearly shown.

Then, during the second period of active life, which corresponds with the disappearance of these reserve-substances, the same phenomena are produced as during the period of formation, but in inverse order: the proportion of amylaceous matters steadily decreases, while the quantity of sugar increases; the saccharose is, at first, in much greater proportion than the glucose; while, at the end of the vegetative period, it is the glucose which preponderates. The process then, to speak generally, is as if the amyloses were transformed into saccharose, and the saccharose into glucose.

The tubers of *Ophrys*, on the one hand, furnish a very clear example of the relation existing between the chemical compositions of the organs with their reserve matter, and when these are developing, and of the part taken by sugars in the formation and destruction of amylaceous reserve. During the period of formation, it seems as though the starch might be formed at the expense of the sugars; during the period of repose the sugars are lacking, and during the period of destruction the starch is digested and submitted to a series of transformations which lead to the saccharose condition, and then to the glucose.

It is to be noticed that with Orchids, as with many other perennial plants, summer is a season of rest, of apparent rest, while winter is the period when vegetation is most active.

The Requirements of Plants under Cultivation.

WE have received the following very interesting and suggestive letter from Mr. H. J. ELWES. It relates to one plant only (*Buphane toxicaria*), but the principles laid down apply to any or all plants in their degree. In considering the propriety of attempting to imitate natural conditions, we must bear in mind not only our inability to reproduce those conditions in their entirety, but also the fact that plants differ very much in their powers of accommodation and pliancy; and, moreover, that in Nature plants have to grow where they can, or where competition allows them to be, not necessarily where they would do best:—

"I have had *Buphane toxicaria* for twenty years or more, and never flowered it till this year. I have never heard of its flowering in England except from newly-imported bulbs, and I think HERBERT says much the same of it. Knowing that the plant was a native of the dry Kalahari desert of South Africa, where the rain is very scanty, the soil very sandy, and the climate excessively dry, I had roasted and starved the plant on a shelf in the greenhouse. When, however, my gardener began to treat it in exactly the same way as we treat *Nerines*, and gave it plenty of liquid-manure during its growing season, the bulb swelled up, became quite hard, and the leaves became much more luxuriant. This year it threw up a flower-spike at the beginning of September. The duration of the flowers is very short, as they were withered when I returned from Norway on October 5. I mention this fact as an additional confirmation of the truth of a theory put forward in your columns some six or eight years ago by the Director of Kew, which led to a very interesting correspondence, in which I opposed his contention. This was briefly, if I remember right, that the empirical knowledge of a clever cultivator would often succeed, when attempts to imitate the natural conditions under which plants grew in their native habitat, by persons who knew them in their own countries failed.

"The longer I live the more convinced I am of the impossibility of imitating the natural conditions of many plants, which are often cultivated successfully under extremely different conditions of soil, climate, and moisture. It seems to me that the constitution of a plant (the term being used exactly in the same sense as it would be if applied to a human being), is one of the most inexplicable things in Nature, and that until we have tried it we can never tell what a plant really wants under cultivation. Often when we have tried it, we are obliged to confess that we cannot tell, but sometimes we discover by accident that the secret of success is something that no one, who knew the plant in Nature, would have suspected. Therefore, I hope that this note may be considered by my friend Mr. THISELTON DYER as a withdrawal of my opposition to his theory; and I must add my congratulations to him and Messrs. NICHOLSON and WATSON on the extraordinary success of their treatment of the many rare, curious, and interesting plants which delight me whenever I go to Kew."

ECHINOCYSTIS LOBATA.*—This is an annual trailing-plant, which will not find favour with those who love brightly-coloured flowers, but the elegance of its habit will commend it to others. It is a Cucurbit native to the North Eastern States of America. The plant is nearly glabrous, with slender, angular stems, palmately-lobed leaves, branching tendrils, and male flowers in branching panicles, the female flowers solitary, shortly-stalked, from the same axil as the male flowers, and ripening into an ovoid greenish berry, studded with small prickles. For the rest, our illustration (fig. 82, p. 271) will suffice. Our specimen was kindly forwarded by Messrs. JAMES VEITCH & SONS, Chelsea.

* *Echinocystis lobata*, Torrey and Gray, ex Gray, *Manual* ed. vi. (1890), p. 195.

ORD.—An interesting account of the herbarium preserved in the Botanic Garden of the University of Padua, recently published at the Clarendon Press. The best collection of dried plants is that made in Italy about 1606 by a Capuchin monk, R. of Reggio. BOBART and MORISON's herbarium next, followed by that of C. DU BOIS. The latter's collection is of great historical value, and

should contain many plants of great horticultural interest. The aim of the present Curator, Mr. DRUCE, is to render the herbarium as complete a representative as possible of the flora of Europe and of the Mediterranean basin.

THE VICTORIA MEDAL.—We understand that the very much honoured 'ones (V. M. H.) are to be

the finest species of the genus, and is a native of New Guinea. The two lower sepals are coherent into a long sheath-like body, and are much longer than any other part of the flower; t. 7557.

Agave Bouchei, Jacobi: one of the few species that have a firm woody trunk, and which do not die after flowering. The leaves are finely toothed at the margins, and the inflorescence is densely spicate.

FIG. 82.—ECHINOCYSTIS LOBATA: HARDY ANNUAL. (SEE P. 270.)

as may be said of that of DILLENIUS. The herbarium forms the basis for the magnificent *Index*, and a number of unpublished water-drawings by FERDINAND BAUER are still in the library. We do not find mention of the interesting collection of DAMPIER'S. The modern collections comprise the FIELD-BARIUM, bequeathed in 1852, and to which additions have been made, particularly the one of the late WILSON SAUNDERS, which

invited to a luncheon at the next meeting of the Royal Horticultural Society on October 26, when the Medals will be conferred on the selected recipients present on the occasion.

THE BOTANICAL MAGAZINE.—The October number contains coloured illustrations and descriptions of the following plants:—

Cirrhopetalum robustum, Rolfe; see *Gardeners' Chronicle*, 1895, i., p. 771, fig. 116. This is the

The plant is a native of Mexico, and flowered at Kew; t. 7558.

Primula sinensis, Sabine: a coloured figure of the wild form is here given, and a summary of its history as recorded in these columns, and in Mr. A. Sutton's paper in the *Journal of the Royal Horticultural Society*, 1891, p. 99; t. 7559.

Calathea rufibarba, Fenzl: a Scitamineous plant of tufted habit, with long, erect, purple-spotted, hairy leaf-stalks articulate at the summit to linear

lanceolate leaf-blades. Flowers yellow, each about 1 inch long, in dense clusters, borne on a short stalk rising directly from the root stock. Kew; t. 7562.

Perisanthes polita, Lawson: a highly curious tropical climber allied to the Vine, but with cordate entire leaves. One of the branches of the tendrill becomes flattened out into a knife-like purplish blade, bearing complete flowers sessile or sunk in little pits, and also incomplete flowers raised on short pedicels. Kew; t. 7563.

THE BOTANIC GARDEN, ZÜRICH.—A hasty run through this garden, founded by Conrad Gesner in the 16th century, enabled us recently to note that the arrangement of the plants is made not only according to morphological characters and natural affinities, but also in accordance with biological peculiarities. There are, for instance, plants selected in illustration of pollination by the wind; others are intended to exemplify the dispersal of the seed by the same agency as in the case of *flügel-früchte*, or winged seeds. Berry-bearing plants are selected as illustrations of the distribution of plants by means of animals or birds. *Salvia* shows how the attractions of the flower are increased by the coloured bracts, "*Erhöhung der auffälligkeit durch extra florale Schauapparate*." The garden contains a bust of HEER, and occupies a pictorial situation on an eminence or old fortification overlooking the town. In one part is a rocky built of red-stone, with deep pockets for the plants. Time, or the want of it, forbade even the slightest examination of details, but the general glance we were enabled to give, sufficed to give the impression that the collection was rich and well cared for. Attached to the garden is an excellent museum, of special interest to students of Swiss botany, recent or pre-historic.

THE SURVEYORS' INSTITUTION.—The first ordinary general meeting of the session 1897-98 will be held on Monday, November 8, 1897, when the president, Mr. CHRISTOPHER OAKLEY, will deliver an opening address. The chair will be taken at 8 o'clock. Those proposing to enter their names for the Students' Preliminary Examination, to be held on January 19 and 20 next, must intimate their intention to the secretary before the last day of November. It is proposed to examine candidates from the counties of Lancashire, Cheshire, Yorkshire, Durham, Cumberland, Westmoreland, and Northumberland, at Manchester. Candidates from other counties in England and Wales will be examined in London. Irish candidates will be examined in Dublin. Students eligible for the Proficiency Examination (which will commence on March 21 next) must give notice of the sub-division (table A of rules) in which they elect to be examined, not later than the last day of October.

ORIGIN OF SPECIES.—We have often referred to the tuberous *Begonia* as presenting an illustration of the artificial production of a species; nay, some have gone so far as to constitute a new genus under the name *Lemoinea*. The *Streptocarpus* hybrids furnish another illustration. A new type has been evolved by the agency of the gardener, and this type has so far become fixed that many of the coloured varieties, and even a pure white one, reproduce themselves from seed.

DRACÆNA WARRENI, HORT.—This is one of the narrow-leaved section; indeed, its graceful, elegantly-curved leaves are almost linear-lanceolate, and of a very rich crimson colour, and very effective for decorative purposes.

GREENHOUSE RHODODENDRONS.—The many double forms of various colours raised in Messrs. VEITCH'S nurseries originated from seed taken from the same capsule. On the contrary, seeds from these double varieties cannot be relied on to reproduce the colour or form of the parent.

NERINE FOTHERGILLI MAJOR.—One of the houses at Messrs. VEITCH'S is ablaze with the brilliant reddish-crimson flowers of this variety. To secure a plentiful production of flowers, the bulbs require to be allowed to become pot-bound.

THE ANNUAL DINNER of the United Horticultural Benefit and Provident Society on Tuesday last

was a distinct success. We are pleased to remark this as an additional evidence of the progress of this useful benefit institution (see p. 278).

MEETING OF THE GHENT CHAMBRE SYNDICALE DES HORTICULTEURS BELGES.—At the last meeting of this society a new *Chrysanthemum*, "*Afsné*," grown from seed obtained by M. Ernest Fierens, secretary of the Ghent Royal Agricultural and Botanic Society, from M. Foutaba, of Tokio, was distinguished by the beautiful ivory whiteness of the flowers, which measure nearly 10 inches across; the florets elegantly bent back, the whole very distinct-looking. M. Bedinghaus showed *Coronilla glauca*, flowering freely. There was a good variegated *Clivia* from M. Paul De Schryver, and *Dracena australis aureostriata* from MM. Carels and Haussens. *Vriesea* *hyb. nov.* (Baron de Sélys), from V. conferta × *psittacina*, raised in the Liège Botanic Garden, and shown by M. Pynaert van Geert, was noticeable for the dark blood-red colouring of the flower. M. Louis De Smet-Duvivier sent an excellent set of seedling *Bertolonias*, with green foliage, streaked and spotted with clearer green, silver-green, and dark yellow. His *Begonia* President Truffaut, and especially his *B. coloris nova*, were very interesting, the latter plant bronze-green, very curious, with greenish-yellow veins with a metallic lustre. *Ch. De B.*

LOUGHBOROUGH AND DISTRICT GARDENERS' ASSOCIATION.—Under the auspices of this association a fruit-show was held in the Corn Exchange, Loughborough, on the 5th inst. During the afternoon a lecture upon fruit culture was delivered by Mr. A. H. PEARSON, of the Chilwell Nurseries, Nottingham, who described the exhibition, which consisted of 300 dishes of fruit, as excellent, and representative in its character. All the fruits were staged by members of the association. The lecture by Mr. PEARSON was considered in every respect helpful and interesting. From Mr. D. ROBERTS, Prestwold Hall Gardens, and Honorary Secretary, we have received the report of the society for 1897, and are pleased to congratulate the members upon its satisfactory character, as showing the society's capacity for usefulness.

THE PEOPLE'S PALACE AND EAST LONDON HORTICULTURAL SOCIETY.—Mr. C. E. OSBORN, F.I.S., Secretary of the above, writes as follows: "I shall be glad if any readers of your paper will kindly send exhibits of *Chrysanthemums* to our next show, on November 11, 12 and 13. Our society numbering about 500 members, consists mostly of working men, who would be delighted to see blooms sent by others living in more congenial districts than the East End."

MR. W. SWAN.—We learn that this well-known Orchid cultivator, and good all-round gardener, is leaving Bystock, Exmouth, in consequence of his employer, J. P. BRYCE, Esq., having relinquished Bystock in favour of a London residence. Mr. SWAN, who has served in the capacity of gardener, bailiff, and general estate manager for several years, will be at liberty in the course of a few weeks.

THE FLÜCKIGER MEDALLIST.—The first award of the medal struck in honour of the late Professor FLÜCKIGER, the eminent pharmacist and collaborator with DANIEL HANBURY, has been made to Mr. E. M. HOLMES, the Curator of the Museum of the Pharmaceutical Society. Those who know the extent and variety of Mr. HOLMES' knowledge of medicinal plants and their products, and appreciate his industry, willingness to oblige, and retiring modesty, will cordially approve of the honour conferred on him by the German Apotheker Verein. Mr. HOLMES' tastes have always been in the direction of horticulture and botany as applied to pharmacy, and his garden at Sevenoaks is also pressed into the service. Mr. HOLMES is one of our most distinguished Algologists.

LILIUM AURATUM.—Our contemporary, the *City Press*, in its issue for October 9, contains a figure of a truss of *Lilium auratum* blooms taken from a plant which, with six others, was grown in a window-box in Cheapside by Mrs. A. A. WOOD. The circumstance,

says the *City Press*, "is certainly noteworthy, and affords further proof, if proof be needed, of the improvement which has of late years manifested itself in the atmospheric conditions of the City." *Lilies* of all kinds are well adapted for town gardening, their foliage enduring for six months only, and that, too, at a time of the year when smoke, blacks, and fog are least prevalent. In conjunction with evergreen shrubs, *Dracena australis*, *Yuccas*, and hardy Ferns, *Lilies* form admirable balcony and window plants.

CONE-DESPOILERS.—A correspondence has lately been going on in the *Times* with reference to the injury which squirrels do to cones, and also to the shoots of Coniferous plants. In the Botanical Museum at Zurich are specimens of cones eaten by field-mice, by squirrels (*eichbörnchen*) and by jays (*habes*), respectively. The mode of attack is different in each case. In one case the effects of the attack of all three depredators are shown on one and the same cone.

"CATALOGUE OF PLANTS AT LA MORTOLA."—We have received the alphabetical catalogue of Plants growing in the open air in the famous garden of Commendatore Thomas Hanbury, Palazzo Orsini, La Mortola, near Ventimiglia, Italy. This list is compiled by Mr. K. Dinter, and comprises the name of the plant, the author's name, the reference to the work in which the plant is described, and indications as to its affinity, native country, and time of flowering. About 4000 species are thus catalogued, a number which will serve to give some idea of the richness of this favoured garden.

ROCK AND SUN-LOVING FERNS.—It is a mistake to consider all Ferns as plants requiring shade and moisture. There are, on the contrary, many which like full sunshine and bright light. Without counting *Cystopteris alpina* and *fragilis*, which grow in our walls as well in sun as in shade, there is one class of Filices which actually require sunshine. *Cheilanthes* from the Old World, as well as those from the new, only do well in a sunny aspect. I have had experience of this for some years. We could not succeed at Geneva in cultivating *Cheilanthes odora*, *lanuginosa*, and *vestita*. In spite of every care given to them, they suffered from general weakness, ending in decay. At last I one day saw *Woodia hyperborea*, that delicate and fragile plant, in full sun along an alpine road in Italy, and an idea occurred to me; and on returning I planted all my *Cheilanthes* in sunshine on a south wall. The result was good, and I recommend the plan to Fern-growers. But it was necessary also to change the soil in which these plants were cultivated, and we set them in soft porous mould composed of sphagnum-moss, peat, and sand; good drainage and frequent watering ensured an immediate and excellent result. That which proved satisfactory for *Cheilanthes* we then tried for *Woodia hyperborea* and *ilvensis* (the treatment did not do for *W. obtusa*); then for *Scolopendrium hemionitis*, that pretty and curious Fern from the South so rarely met with in gardens, where it is considered difficult to grow. Then we subjected to the same treatment our *Nothochloa Maranta*; and these lovely Ferns, which formerly did not do successfully with us, turned out marvellously well. It is, then, absolutely certain that many species of Ferns—examples could be multiplied—require sun and plenty of air. While on the subject of Ferns, I wish to mention a curious case of fructification on both surfaces of a *Scolopendrium*; the spores are even more numerous on the upper surface than underneath the frond. This phenomenon I never observed before; it occurred in the Jardin Alpin d'Acclimatation on a plant raised there from spores. H. Correvin, Geneva.

FLOWERS IN SEASON.—Some glorious bunches of early-flowering *Chrysanthemums* reach us from the Scots nursery of Messrs. DOBBIE & Co., at Rothesay. They are all very beautiful, and no plea for their cultivation need be urged when they afford such flowers from an open field so late as October 8. It may be questioned if it be advisable to seek to obtain large-flowered varieties in bloom during September, whilst Roses and annual Asters are still

moderately plentiful; but as to the small, prettily-tinted varieties represented by those before us, their presence during that month is altogether desirable. They are the forerunners, the promise of the larger, handsome *Chrysanthemum* blooms that help so greatly to enliven the month of November—naturally the duller in the whole year. As we look at some of the flowers, the close resemblance in colour to most of the vegetation at this season is very noticeable; they combine a large number of exquisite autumn tints. This section of *Chrysanthemum* has this season been put upon its trial in the gardens at Chiswick, and the judgment of the Floral Committee of the Royal Horticultural Society has been passed upon the varieties there. There are now a fair number of sorts that bear the recommendation of this committee, and some notes upon the best of those that bloomed in September appeared in the *Gardeners' Chronicle* of last week, p. 247. Grouping the varieties from Messrs. DOBBIE & Co. into colours, we find we have white flowers (or pale yellow ones that we will deem as white), including Mrs. Cullingford and M. C. Desgranges; pale pink, such as Longfellow and Mrs. Pitcher; deep pink and rose-coloured varieties, including Madame Marie Masse, Strathmeath, Le Poete des Chrysanthèmes, and Blushing Bride; deep reddish-brown flowers, with various shades of bronze and gold upon some of them, including Alice Butler, Scarlet Gem, Bronze Bride, &c.; various shades of buff and apricot, illustrated by the varieties Percy's Seedling and La Luxembourg; and bright yellows of the style of *Précocité*, G. Wermig, and Flora.

— Some fine spikes of the distinct *Antirrhinum Hendersoni* are sent us by Mr. J. W. FORBES, Beaulieu Nurseries, Hawick, N.B. The ground-colour is white, with a belt of violet-purple round the margin of the segments, and across the pouch. The variety is as old as it is distinct, but is not frequently seen.

STOCK-TAKING: SEPTEMBER.—It is again satisfactory to note an increase in the Revenue receipts for the second quarter of the financial year, as compared with the same period last year. The increase is not very marked, but still it is an increase, and helps to bring up the increase to over a million sterling for the half year, compared with the first half of the financial year in 1896. The Board of Trade Returns show an improvement on the side of imports to the tune of £2,189,547. The total amount for the month of September was £35,195,893, against £33,006,346 for the same month in the preceding year. The greatest increase is to be found in articles of food and drink, duty free, £1,357,663; also of £343,167 on dutiable articles; timber figures largely in the "increase" column; "raw materials for sundry industries and manufactures," £921,707. There is a decrease in "raw materials for textile manufactures" of £577,810. The following is extracted from the "summary" table of imports:—

Imports.	1896.	1897.	Difference.
Total value ...	£ 33,006,346	£ 35,195,893	+ 2,189,547
(A.) Articles of food and drink—duty free ...	11,218,704	12,576,367	+ 1,357,663
(B.) Articles of food and drink—dutiable ...	2,282,855	2,626,022	+ 343,167
Raw materials for textile manufactures ...	2,576,346	1,998,536	- 577,810
Raw materials for sundry industries and manufactures ...	4,541,461	5,463,168	+ 921,707
(C.) Miscellaneous articles ...	1,155,708	1,023,637	- 132,071
(B.) Parcel Post ...	102,500	76,522	- 25,978

The fall in the prices of cereals recorded week by week in our little table is in great part due to increased imports; but there is no decline noticeable in the price of bread. The value of the imports for the past nine months foots up at £329,958,835, against £316,293,512 in the previous year—an increase of £13,665,323. It may not be amiss to notice here the latest reliable statistics

connected with the competition of our Teutonic friends. The statistics inform us that the United Kingdom holds the most important place in the list of countries trading with Germany; this, however, applies to imports into Germany from us as well as to Germany's exports to here. In 1893 the value of German exports to this country showed a nominal increase of £35,700,000 as compared with £33,900,000 in 1895; but the proportion borne by these exports to the United Kingdom to the amount of Germany's total exports shows a decline—the figures for the last four years being, 1893, 20.7 per cent.; 1894, 20.8 per cent.; 1895, 19.8 per cent.; 1896, 19 per cent. In the figures relating to German imports from the United Kingdom, there is no cause for alarm. Our share of the imports into Germany last year was 14.2 per cent., as compared with 13.6 per cent. in 1895; while in regard to value, the figures rose from £28,900,000 in 1895 to £32,360,000 in 1896. Coming now to the imports of fruit, roots, and vegetables for the past month, we place our useful and usual little table before the reader, as follows:—

Imports.	1896.	1897.	Difference.
Fruits, raw:—			
Apples ... bush.	682,735	247,653	- 435,082
Cherries ... "
Plums ... "	63,845	379,014	+ 315,169
Pears ... "	126,014	311,575	+ 185,561
Grapes ... "	231,564	217,790	- 13,774
Unenumerated ... "	157,224	251,154	+ 93,930
Onions ... "	703,227	755,499	+ 52,272
Potatoes ... cwt.	36,493	91,895	+ 55,402
Vegetables, raw, unenumerated ... value	£108,807	£112,747	+ £3,940

The "differences" in the above will be fully appreciated by all interested. It may not be out of place here to notice that the commission appointed to consider the condition of our West Indian possessions have nearly finished their labours, and the majority are in favour of helping the complaining islanders in the multiplication of baskets in which to carry their eggs to market—to subsidise carrying companies in the way of steamers and the organisation of botanic gardens, so as by this means to introduce fresh products in the way of fruits and vegetables for exportation to the United States and to the Mother Country. This may enable those now suffering from bad sugar markets to become, to some extent, independent of them. Our

EXPORTS

now demand attention. The total value for last month was £18,305,275, against £19,824,125, or a fall amounting to £1,518,850. Under the heading, "Articles Manufactured and Partly Manufactured," viz., "Yarns and Textile Fabrics," the decrease is £1,364,580. Further we need not go. Little use here to account, or try to account, for the falling off. The decrease for the nine months is placed at £4,664,624. As we all know, the social warfare continues its ruinous work—"pity 'tis, 'tis true."

NEW PLANTS (?) OF THE SWAZI SURVEY.

Novelties will never come to an end if they are accepted on the representation of unscientific explorers, as we fear they often are. A correspondent, writing from Cape Colony recently, encloses a cutting from the *Star* (South African):—

NEW PLANTS AND BIRDS.

"A *Star* (Cape Town Journal) reporter had recently the pleasure of an interview with Mr. VOS WELLMAN, formerly State Surveyor-General, who had just returned from Swaziland, where he was engaged in surveying the Vermaak Concession, in the southern part of that interesting land. The returned traveller was full of news, and willingly parted with it when questioned. "I have some news," he began, which will be of interest to Mr. CHAMBERLAIN, namely, that in Swaziland, and different parts of the Transvaal, I have encountered no less than thirty new varieties of Orchids, which have never yet been cultivated. One of these possesses a bulb scented something like eau de cologne, and possessing the largest flower I have seen amongst the South African Orchids. In Swaziland I found at least eight new Lilies. One of these is called by the Swazis *Umfana amacetwana*, and when it is partaken of, the incautious eater froths at the

mouth and falls in convulsions, which speedily end in death. The Lilies were pure white, with dark purple inside, yellow with the same internal colouring, light pink, pink, and crimson. Instead of the usual arrow-shaped leaf, two varieties had trefoil and oblong elliptical leaves respectively. I found also a Lily of the Valley in Swaziland of a beautiful orange colour. Gladioli were in lavish abundance, including the Green Giant, with leaves 3 inches in length. Water Lilies of all kinds were to be found, though it was sometimes hard to secure specimens. I asked a Kafir to go into a certain pool for a Lily, and offered him £10; but he replied that he would not go in for ten oxen. Crocodiles? Yes; the place was swarming with them. A particularly beautiful item I came across was a tree covered all over with white flowers bordered with red. It must be very rare. Hundreds of the rarest Ferns are constantly met with. For instance, *Osmunda regalis* fetches about 7s. 6d. a piece in Capetown; but where I was you could take away waggons-loads of it. Of course, there was every variety of Tree Fern. A very striking bird is to be found about the parts I was engaged in surveying. It is only heard singing when the sun is setting, and then it runs clean up the diatonic scale, being answered in the distance by its mate. Many birds of remarkable plumage, and several of the pigeon kind, which I have never seen before, frequent the groves. I was especially interested in a variety of green pigeons. What about game? Game is fast disappearing, but the Pongola reserve is still full. There are also plenty of all kinds of animals in the dense forests of the Lobongo flats, which the Boers call "stables," because the hunted beasts can run there and be safe."

Explorers, for the purposes of survey, often imagine they are the first to see the flora of a, to them, new country; but, in the majority of instances, the botanical traveller or trader interested in plants, has been before them, and specimens of the plants they imagine to be new are often common in British gardens, or well represented in herbaria. Even in the case of a positively newly-discovered country, it by no means follows that even a small proportion of the plants should be new, if the surrounding country has been previously explored and opened up. That most of the so-called Orchids will not be Orchids at all is highly probable. In the so-called new Lilies it is not difficult to recognise *Richardia melanoleuca*, *R. Rahmanni*, *R. Pentlandi*, *R. Elliotiana*, or other varieties of *R. hirtata*; and in the orange-coloured Lily of the Valley, *Sandersonia aurantiaca*. For the rest, *Crinum* and *Valottia*, generally called Lilies, will probably supply their proportion of the wonders.

THE WELSH VINEYARDS.—We have received a statement from Mr. PETTIGREW, gardener at Cardiff Castle, upon the yield of vintage-Grapes from the vineyards of the Marquess of Bute, in several localities in Glamorganshire. Three bunches of Grapes, of the variety "Gammy Noir," which accompany the letter, are sent as being typical of the produce from the vineyard at Swanbridge. They differ considerably in weight, the heaviest being nearly double that of the smallest bunch; together, they weigh 23 ozs., thus averaging nearly $\frac{1}{2}$ lb. per bunch. The crop is described as greater than in any previous year, and as the present writer in 1893 observed upon the same Vines an average of about a dozen bunches per Vine, the crop should prove this season to be about 6 lb. of Grapes per Vine. The berries are not so sweet as in several former years, but they appear well developed, and of capital colour. The indifferent weather during August and September is blamed for the deficiency in sugar. Nevertheless, Mr. PETTIGREW estimates a vintage of about thirty hogsheads of excellent wine, and we assume a little cane-sugar will be added to compensate the deficiency of Grape-sugar. The vintage was commenced on the 7th inst., and lasted four or five days. The Swanbridge Vineyard is close to the sea-beach, not a great distance from the growing docks at Barry. The land slopes a little to the south-west, and towards the sea. The red soil is very stony, and in some places not more than 1 foot above the rocks. At the other vineyard, at Castell Coch, about 5 miles upon the other side of Cardiff, and some distance from the sea, the crop of Grapes, which early in the season promised to be good, has been practically ruined by mildew. There are 4 acres there, the Vines are a little older than those at Swanbridge, and the site is different, the slope being much more acute. At the top is a plantation of forest trees that surrounds the ancient

castle. It is possible that during very dry seasons, such as this one was until the end of July, the soil upon the slope becomes too dry. At any rate, trees and hedges alike suffered from mildew two months ago when we visited the place, and it was said that the fungus first spread from the hedges to the Vines. The Bordeaux Mixture has been used repeatedly, and all measures that the continental growers use to combat the mildew have been adopted with little success. At Swanbridge the Vines are not attacked by the pest at all, and this vineyard will consequently pay very much better than that at Castell Coch on account of the extra yield. Upon the whole, it is satisfactory to find that the yield of Grapes for the present year will be a decidedly remunerative one, and the question arises, whether it would not be worth while to attempt the cultivation of vintage Grapes in favourable localities on the south coast, say, in Sussex and Hampshire.

TECHNICAL INSTRUCTION IN HUNTS.—Mr. THOMAS BUNYARD has been appointed Instructor in Horticulture for a few weeks in this county, and gave his first lecture on Monday at Great Gidding, the other two centres being Winwick and Thurning. The audiences have been fairly good, but the "Feasts" peculiar to this part of England at this season keep many away, and we can hardly blame the agricultural labourer that he prefers a good substantial dinner to going to a cold school-room to listen to instruction in gardening.

PUBLICATIONS RECEIVED.—*Lorna Doone* (R. D. BLACKMORE), a cheap sixpenny edition of this popular novel (SAMPSON, LOW, MARSTON & Co., Ltd.).—*Proceedings and Journal of the Agricultural and Horticultural Society of India*, for April to June, 1897. Among the contents is an interesting paper by Mr. A. M. Sawyer, contributed to the "Indian Forester" on the subject of Tapioca Cultivation in Travancore.—*Proceedings of the Agri-Horticultural Society of Madras*, April to June, 1897; contains a list of plants in flower, and of plants received and sent out.—*Bulletin of the Botanical Department, Jamaica*, April to June. This includes notes on Satin Wood (*Fagra flava*), with two illustrative plates; Pea-nut (*Arachis hypogæa*), Oil-tree (*Prioria copaifera*), Coccidæ or Scale Insects, and Synoptical List of Ferns.—*Queensland Agricultural Journal*, August. Contains articles on: the Agricultural Possibilities of Western Queensland, Maize-growing on Scrub lands, the Velvet Bear (*Dolichos multiflorus*), Fruit Culture in Queensland, Grape Fruit, Scale (Coccidæ), Caoutchouc, and other subjects connected with crops and live stock.—*Fungus Diseases of the Raspberry*. Issued by the Department of Agriculture, Victoria. A pamphlet, by Mr. D. McAlpine, on the Raspberry-root fungus (*Hypholoma fasciculare*), and the Raspberry anthracnose or *Gleosporium venetum*. Full and illustrated descriptions of these pests are given, with directions for coping with them.—*The Land of Sunshine*. A magazine of California, edited by CHAS. T. LUMMIS, contains a paper on collecting Californian Ferns, which is described as being "superbly illustrated," and other articles descriptive of Los Angeles and the district. It is the August number that is now before us.—*Erythea*. A Journal of Botany, West American and General. The August number contains Notes on Californian Bryophytes (continued) by M. A. HOWE.—*Nature Notes*, October.

STREPTOCARPUS WENDLANDI.

THE illustration of this fine and very singular species (fig. 83), represents a group grown by Mr. F. Parfitt, gr. to E. Horne, Esq., South Park, Reigate. The plants were sent for exhibition to the local flower show on July 31 last, and there attracted much notice, being so novel and of such quaint appearance. The strain is that of Messrs. Sutton & Sons, Reading, and Mr. Horne's stock was from a seedling plant kindly sent by Mr. G. F. Wilson, of Weybridge. Mr. Parfitt's treatment, which produces such fine plants, is to sow seed in June in a shallow pan, and on fine sandy

soil, and, of course, under glass. So rapidly do the seedlings grow, that they may be shifted at once from the pans into small sixties, and be placed in a close cool frame. By this comparatively hardy treatment the pots are soon filled with roots. A further shift into 48's is made, and finally into 24's. The compost consists of good turfy loam and well-decayed leaf-soil, with a fair infusion of sharp sand. The pots should be given ample drainage. During the winter, the plants being put into a greenhouse, the temperature ranges from 45° to 55°. The plants figured were in height from 30 to 36 inches, and the base leaves were 28 inches wide and 22 inches deep. The inflorescence was abundant, and very pleasing. A few such plants would be capital features in a decorative group. Mr. Horne's gardener merits all praise for the specimens of this *Streptocarpus* his cultivation has produced.

HOME CORRESPONDENCE.

JUBILEE CARPET-BEDS.—What hope is there for English gardens when such a work of tasteless ingenuity as the "Jubilee-bed," described in your issue of the 2nd, is considered the pride of one of the finest gardens in the land? To what end is this carpet-bedding manufactured? If for the admiration of visitors who crowd past it in hundreds, ought so false a taste to be encouraged? The ingenuity displayed is certainly praiseworthy; but what more is there to be said for the diamond centre and the crowns and the monograms, and the whole arrangement? When "Hampton Court" appeared in the table of contents of the *Gardeners' Chronicle* of Saturday last, I turned eagerly to the page, hoping to find the description of something new and beautiful; some special arrangement of fine colours only to be obtained on a grand scale, such as a purple mist of *Salvia* (*Bluebeard*, or is it *sylvestris*?) contrasted with the yellow-gold of the old-fashioned Golden Rod; or a fine arrangement of *Galtonias*, or the like. Alas, for the disappointment! After the Great Vine, which can never be uninteresting, came an account of the great Jubilee-bed, with its diadems and royal cyphers. A triumph of patience and gardeners' art, but is it a triumph of garden-craft? And is our beloved Queen honoured by any such thing so greatly, as if some other thing of equally costly, but of exceeding beauty had been arranged in that large oblong bed? Happy is the gardener who has the power to exercise good taste and skill on a scale so large as that of Hampton Court. We, of the puny little private plots and garden grounds, where we are continually thwarted by want of space, know only too well. E. V. B. [This kind of thing has not any of our sympathy or admiration, and the Hampton Court bed was merely instanced as affording our readers an idea of Jubilee horticultural exuberance. Several such beds may be, or were, found in other London parks, this year; and they find plenty of admirers. Ed.]

CAMOENSIA MAXIMA.—This shy-flowering leguminous climber is now in bloom in the Palm-house here. It was planted about three years ago under the stage, and trained to the roof. During this time it has reached the top of the annexe, a distance of about 20 feet. The growth was restricted to three shoots, and it is upon the well-ripened side-growths that most of the thirteen indefinite inflorescences have made their appearance. The number of flowers upon each raceme varies from sixteen to eighteen. These racemes are all axillary, and generally near the apex of the branches. About four months since the plant was severely root-pruned, and several large roots thicker than an ordinary pencil were cut. Whether this has hastened its flowering I cannot say; certainly the growth was checked, for another plant in the same house is now quite 30 feet high. No shading was given at any time. A description of these lovely flowers was given with figures in the *Gardeners' Chronicle* for November 14, 1896, p. 596. R. L. Harrow, Royal Botanic Gardens, Edinburgh.

"VENN'S BLACK MUSCAT."—Re, the bunch of Grapes sent last week, I observe you are asking for particulars of treatment of the same. I cannot speak regarding the starting of the vine, as I took over these gardens last March. There are several varieties grown in the same vine, namely, Muscat of Alex-

andria, Black Alicante, Black Hamburgh, and Venn's Black Muscat. The Vine-border has been watered once every three weeks, with water of the same temperature as the vinery, which was kept from 70° to 75°. After the Grapes began to colour, water was afforded once in four weeks, air being given at top and front as weather permitted. This week we have carefully examined the border, and find trace anything that would be accountable, except that the Vine seems to be very old. Would sufficient water at the commencement be the cause? When I took over these gardens I found the border in a very dry state; the Vine has not looked healthy all the summer. Vine. [Unless the border is thoroughly saturated, which could only be attained by excavating a small hole here and there down to the drainage, or uncovering the outlet drain, and seeing if any water had recently passed along, the border may still be in a dry state, the water afforded having been absorbed by the surface.] So much depends upon the kind of soil, its porosity or otherwise, depth of soil, number of drains, and of the surface, width of the border, if it be inside or outside or both. Your note affords no clue. Grapes were virtually converted into Raisins. how? Ed.]

THE LOQUAT, OR JAPANESE MEDLAR.—I have been interested by the correspondence between Clarke and Mr. George Harris, of the Ducal Gardens, Alnwick, in these pages; and I agree with Mr. Harris as to the character, form, size, and colour of the Loquat. I grew the plant for years on the back of a vine. The plant generally flowers abundantly in November in a temperature never lower than 45°, the flowers being greenish-white, with the odor of the Hawthorn. The time of ripening of the fruit varied considerably with the season. The plant is a shy fruiter, considering the prodigality of the blossoms. In some years the quality of the fruit is excellent, and if we judge the flavour of the fruit by its aroma, a rather comparison as a rule, we may take it that the flavour should be good. Rats will devour the fruit readily when on the verge of maturity; and, possessing an aroma so powerful that it pervaded all of glasshouses 300 feet in length. D. T. F.

THE PICTURE OF CATTLEYA SCHOFIELD GIGANTEA.—Some of my gardening friends remark that I have not given the name of the artist who painted Mr. Gratrix's flower, from which figure in the last issue of the *Gardeners' Chronicle* was taken. He is the son of Mr. Mitchell, who for twenty years gardener to the late Dr. Ainsworth of the Cliffe, Lower Broughton, Manchester. During that period Mr. Mitchell, sen., raised the two last crosses *D. Ainsworthii* and *D. Ainsworthii rosea*, which, along with other blood, has altered and proved the character of many of the progeny now in commerce. Young Marshall had a good school at his father's home in which to practice the delineation of Orchids, and he has done some excellent work. It was taken in hand by the Orchid Committee of Manchester and North of England Society, and painted for that committee's Records every picture that has received a First-class Certificate, and upon the whole he has done his work well. He painted illustrations of Mr. Rappert's *Cattleya Mossii* and *partiana*, and of Mr. Gratrix's *Cattleya Schofield gigantea*, his best drawings, and both have been illustrated in the *Gardeners' Chronicle*. J. A.

BOUGAINVILLEA GLABRA.—A fine plant is flowering in the corridor here, where it has a good house temperature, and grows vigorously, and flowers in the greatest profusion. I am inclined to think with "A. D." who in your issue of the 3rd suggests that a low temperature tends to produce richer colourings in the bracts. This same plant has been grown in the stove and Palm-house, and neither was the colour so intense as now. In a letter by Mr. J. Benbow, Abbotsbury Castle Gardens, Dorsetshire, in the *Gardeners' Chronicle* for December 1893, he mentions a plant as growing out of doors in a south wall, and on the date of his writing it withstood 5° of frost without losing its foliage, which would be interesting to know if any increase in the depth of colour was noticed in cases of a plant grown out of doors. R. L. H., Royal Botanic Gardens, Edinburgh.

DO ORCHIDS DEGENERATE?—After many years' experience, I, for one, can answer, yes! There are instances on record of *Cattleyas* and other Orchids being kept in health for a great number of years.

on *Vanda coerulea* as one that I have been with for a lengthened period; *Saccolabium* have seen growing in the temperature of a house for twelve years, flowering it well and for some years before I was acquainted. Now to name a few that do decidedly well: *Cattleya Dowiana*, *C. superba*, *Epidenmutum*, a beautiful Orchid when in flower sweet-scented *Phalenopsis*-like blooms. to the roof-glass of a Pine-stove, and you are rewarded with success for a year or two, then it "growing less" follows. Bolleas and I, I did well for a period of six years, and mented by all who saw them. One grower my success to a tree that cast its shade house just outside; however, the tree did not from degenerating. *Lælia harpophylla* the same house. One home-made bulb fine flowers upon a spike, the following seven, and there were fewer afterwards. *Lundesboroughianum*, another charming when in flower, refuses to grow after it in this country for a few years. *Oncidium*

more credit to the cultivator, than 5000 with limited space and means. What a wretched sight is a batch of *Odontoglossum Roezli* or *O. vexillarium* which are disfigured by thrip! The last-named plant I grew from a small plant into a beautiful specimen. It was exhibited at the Royal Horticultural Society's Gardens, and awarded a Silver Medal for good culture. The following year all the flower-spikes were pinched out as soon as they showed themselves, hoping to be doubly successful with it the next year, but alas! yellow thrip attacked it, tobacco-smoke, and dipping with insecticides were resorted to, causing the loss of a good many old leaves; eventually the plant was split up and repotted, but it never regained its former health and vigour. Another cause for degeneracy is the trying British winters we sometimes have, that of 1890 for instance, when no air could be admitted for weeks without lowering the temperature too much; and through an insufficiency of hot-water piping, a "fiery" smell is produced, which would make a sensitive man shudder as he entered the house, and exclaim this is not the place for Orchids! He is quite right, the conditions

years ago still in existence, both at Chatsworth and Bilton. I think I have shown that some Orchids do degenerate, but surely not to such an extent as to deter old enthusiasts from continuing their culture, or young ones from continuing it. Apart from the commercial value or speculative interest, they give abundant pleasure to ladies and gentlemen who are fond of seeing Nature in her most lovely and brightest garb. *Thomas Simcoe, Cardiff.*

PRESERVING DAHLIA ROOTS IN WINTER.—The recent frosts have settled most of the Dahlias for this season, and it is only in sheltered spots that they may yet produce a few tardy blossoms. In the open they are black to the roots, and the rot which follows frost will soon pervade the stalks and branches. There is reason to believe but comparatively little seed will be saved this season, owing to the general late bloom, owing first to the drought, and then the rains which followed caused the plants to put forth growth when they should be flowering. All plants destroyed by the frost may be cut over, leaving a foot to 18 inches of the main stem. As there is no knowing how soon sharp weather may set in, it will be wise, as a matter of precaution, to lift the roots without delay, choosing a fine and drying day for the purpose. It is well to spread a garden-mat on the ground, and as the roots are dug up, crumble away a good deal of the soil upon them, and then turn them upside down upon the mat, as then any moisture in the remains of the hollow main-stem will drain away; after being exposed to the sun and air for a time, more of the soil will crumble away, and then the roots should be either housed, or if left in the open all night, carefully covered over. When finally housed, it is well not to wash the roots, as is recommended by some, but allow what little soil is left upon them to crumble away into dust. Where and how the roots should be wintered is a matter of convenience to some extent. They will winter well on a dry shelf, in a cool, airy place, cool, not warm, as only sufficient warmth is needed to exclude frost. Glenny's advice is as sound to-day as it was forty years ago: "Dahlia-tubers should be kept where neither heat, nor damp, nor frost can reach them." Some Dahlia-growers among the Lancashire operatives have been known to hang their tubers up suspended from the walls of their living-rooms. Some bury their tubers in sand, or in any dry material which can be procured. Shelves in some dry, cool, frost-proof out-house or cellar are best. I have known roots preserved under the plant-stage of a greenhouse, and though drip fell upon them occasionally, they received little or no injury. But wherever they are placed, it should be where they can be examined at any time, as some roots do not winter well; there appears to exist an inherent tendency to decay. Those who preserved in the best manner have experience of this. No one would think of placing under a greenhouse-stage roots of very choice and rare varieties, but if from necessity the commoner sorts have to be placed there, they should not be placed in a heap, but laid out singly, so that the water, which cannot fail to fall upon them every time it is given to the plants, may lodge about them as little as possible. Even the preservation of Dahlia-roots during winter is not without its anxieties. *R. D.* [One of the best means we know of for preserving the roots of Dahlias, Cannas, *Salvia patens*, and *Marvel of Peru* is to place them on the floor of a dry cellar in a single layer, and cover them 2 inches deep in finely-sifted coal or wood-ashes, or the charred refuse from the garden bonfire, or charred earth. We have known the roots thus stored come out quite sound after an ordeal of 4° to 6° of frost; but they are safer if frost do not reach them. The evaporation of moisture from the tubers is arrested by the covering, and they are almost as plump in February as when stored, which is not the case with tubers stored like Apples on dry shelves. *Ed*]

83.—STREPTOCARPUS WENDLANDI IN THE GARDEN OF E. HORNE, ESQ., PARKE, REIGATE. (SEE P. 274.)

and its varieties, including *O. Marshallianum*, apt for years, but strength and vigour are gained. The same remark applies to that, *O. Jonesianum*; also to its giant ally, *O. n.* I have gazed upon the latter almost when I have seen it growing vigorously and profusely. Some of the *Dendrobies*, *McCarthyi*, *D. formosum*, *D. Dearei*, and *D.* are unsatisfactory after a time; but *D. formosum* you for all the pains you bestow upon it for late autumn flowering. Ask that champion grower, Mr. J. Cypher, of Cheltenham, thinks of it as a useful Orchid? I have seen odd form there—such bulbs! and such bloom! truly gigantic. Whether he can be successful with the other "miffy doers" now, not having seen them for the last five years. *Bensoni* used to be grown wonderfully year after year. I think that yellow thrip and more degeneracy amongst Orchids than ing. How many are the collections that are ruined by this insect! There are two aspects with this subject which are overlooked people. One is, that Orchids infested with thrip are dear at any price; moreover, 500 should be better looked after, and grown with

are so unnatural. Need one wonder at the sickly-looking leaves under such conditions, more particularly in a house of *Cattleyas*? The modern-built Orchid-house, lofty and very light, is much better adapted for preparing certain classes of Orchids to withstand the rigours of a severe winter than the old dwarf and darker structures. In the former, the pseudo-bulbs can be well-ripened and hardened, and they will pass through a much lower temperature uninjured during the resting season, and, of course, flower much better when well-matured. It is very pleasing to see in some of the great trade collections house after house full of plants, with that beautiful dark green hue indicative of health. The question may be asked, Do they flower as well or live as long as those grown under different conditions in an amateur's collection? Since writing these notes, I have read the excellent list of Sir Trevor Lawrence's. It is just the place one would expect to hear of a goodly number of good old Orchids, as well as some of the newer ones being successfully cultivated for many years. The most remarkable plant to my mind in the list is *Vanda Lowii*. As regards *Renanthera coccinea*, the great difficulty with that is to flower it (not to keep it). I think there are plants of the original imported forty or fifty

STIPA TENACISSIMA, L.—Desfontaines, *Flora Atlantica*, t. 30. North Africa, Spain (up to 4000 ft.) on sand-hills and plains, also in Portugal, Greece, "Esparto," "Atocha," "Alfa," "Sarte," "Kawil" (Russian), "Fejér Árva" height, about 2½ feet, leaves the beard hairy at base. One of the same species ancient, and was introduced is very common on the arid become very important as a material for import of tons, wh In 1889,

vegetable fibres for paper-mills 385,000 tons, representing a value of over 2,000,000 pounds sterling. Algeria and Tunis export yearly 60,000,000 tons of raw material. But now it is planned to build a large paper-mill in the southern part of Tunis. As 75 per cent. of the English newspapers contains Esparto as material, this matter is of the greatest importance to England. The plant grows in any soil, whatever it may be; even in the scorching heat of the Sahara it maintains itself. Extensive culture of this grass exists in the south of France. It is pulled once a year in the earlier part of summer. *M. Buysman, Hortus Plantarum Diaphoricarum, Middelburg, Holland.*

LAW NOTES.

ASHWORTH v. MATTHEW WELLS.

At the Manchester County Court, Judge Parry gave his decision in the case of Ashworth v. Matthew Wells, which was an action to recover damages for breach of warranty. His Honour, in giving judgment, said the facts of the case were these. In June the plaintiff sold to the defendant an Orchid undeveloped, but warranted by name to the plaintiff as *Cattleya Aclandiae alba*. The Orchid was sold at an open auction, at which many Orchid-growers were present, and fetched £21. Ultimately the Orchid developed into a common purple *Cattleya*, value 7s. 6d. No one had ever grown or seen a *Cattleya Aclandiae alba*, but Orchid-growers were of opinion that such a plant would, if it existed, be worth at least £50, and would probably fetch a much larger sum. The only question in dispute now was what was the measure of damages consequent on the breach of warranty, that the Orchid was "alba." The defendant was ready to repay the money he received for the Orchid, but the plaintiff claimed a sum equal to the price he might have obtained for such an Orchid if it had proved to be "alba." His Honour having quoted the authorities on the case, said that he could find no case in which the failure to make a probable profit had been even claimed, much less allowed, as damages for breach of warranty, and inferentially, the case of *Randall v. Roper* showed that such a claim would not be allowed. It seemed to him that it should be shown that some actual loss had been sustained, and that it was not enough that there should be some possible loss. If the plaintiff found out at once that the plant sold was not as warranted he could have his money returned. If he reasonably expended money in the development of the plant that money ought also to be returned. If he resold the plant with the same warranty, and had to settle a claim against him, that also might be included in his damages. But the failure to make an anticipated profit—in this particular case a highly speculative profit—could not in any opinion be included in the damages naturally consequent on the defendant's breach of warranty. He was further convinced that such anticipated profits could not be recovered as damages for breach of warranty by the judgment in the case of *Peterson v. Ayre*, which was one of the cases considered in *Randall v. Roper*. Under these circumstances he thought the defendant had paid sufficient money into court, and was therefore entitled to judgment with costs. The plaintiff had leave to take the money out of court on payment to defendant of his taxed costs.

SOCIETIES.

ROYAL HORTICULTURAL. SECOND DAY'S CONFERENCE.

(Continued from p. 259.)

THE PROGRESS IN VEGETABLE CULTIVATION DURING QUEEN VICTORIA'S REIGN.

OCTOBER 1.—P. CROWLEY, Esq., presided at the second day's conference, when Mr. MARTIN J. SUTTON, of Reading, read a paper on the above subject:—

In sketching the outline of my paper I felt that I could not do better than take the leading vegetables, enumerating the kinds in cultivation in 1837, and then briefly mention the improvements that have since followed. It is obvious that unless there had been a very marked advance in

the vegetables grown, the progress in cultivation would have been comparatively insignificant. In saying this, I do not for a moment suggest that the gardeners of to-day are not far in advance of those of 1837, but that whatever method of culture might be adopted, no very great advance would be possible without improved vegetables to work upon. Without further introduction I will proceed at once to the all-important subject of the

GARDEN PEAS.

Without hesitation I may say that the progress made during the last sixty years in the improvement of the Garden Peas has been fully commensurate with the position this vegetable occupies, and which may fairly be called the Prince of all Vegetables. I think also I am correct in saying that this proud position has been attained solely through the progress made in its improvement since 1837; an evolution truly marvellous, as I think all will admit when we compare the Peas of 1897 with those of 1837. In the thirties and for many subsequent years the gentleman's garden—as well as the market garden—was dependent upon such varieties as Woodford's, Bedman's Imperial, Scimitar, Early Charlton, Warner's Emperor, Early May, McCormick's Prince Albert, and Early Warwick, the other principal sorts cultivated being Blue Prussian, Bishop's Early Dwarf, and Auvergne. These are Peas which we, with more cultured taste and better varieties at our disposal, now look upon as chiefly suitable for boiling in a dry state. Knight's Tall Green Marrow, a wrinkled Pea, was certainly available at this time, but was not so generally grown as the round-seeded sorts, which an old gardener now living informs me were so hard and dry when cooked that they were known as Buckshot Peas.

During the next decade, a few varieties such as Sangster's No. 1, Champion of England, British Queen, and Hair's Dwarf Mammoth, were added to the list, the first three of which are still largely grown by those who have had no opportunity of testing better sorts; but no considerable interest was awakened until the advent of that popular favourite, "Ne Plus Ultra," which was introduced under three or four names in as many successive seasons. Even at the present day, when testing year by year all the so-called novelties as they appear, we frequently find that still another name has been added to the already long list and which "Ne Plus Ultra" is offered. Of its class, as a tall late Marrow Pea, it is doubtful if any later introduction has ever shown, comparatively, a greater advance on previous kinds.

In passing, it may be of interest to some to know that three of the principal Peas distributed by my house in 1841 were Blue Prussian, Woodford's, and Scimitar, from which we may form a fairly correct idea of the class of Peas then grown by gardeners.

Up to 1857 there had been introduced Daniel O'Rourke and our Early Champion as representing improved types of early Peas; and Glory, Climax, Dickson's Favourite, Prize-taker, and Epps's Lord Raglan.

In 1859 that popular Pea, Veitch's Perfection, was introduced, and in the same year also the first selections of Dr. McLean's seedlings were put on the market by Mr. Charles Turner, including Princess Royal, followed a few years later by Little Gem, and these continued to be favourites for a quarter of a century. This was the commencement of that period of activity which has extended with increased vigour till the present day,—the skilful hand of the hybridiser in conjunction with the keen eye of the expert producing such Peas as Her Majesty's gardener never dreamt of in 1837. Here I may remark that the work of selecting is in no degree less important than that of hybridising. This will be better understood when I explain that a seedling Pea is now generally the result of so much inter-breeding that very many distinct types will often be represented in the ultimate cross. This cross will give a pod containing from six to ten or more seeds, and it is at this point the work of the hybridiser ceases and that of the selector commences, but it is only a commencement.

When sown the following year, these seeds will, in all probability, produce as many distinct seedling Peas, some partaking of the character of the parents and some not; but the difficulty increases when we find that seed saved from each of these plants very frequently varies in each case to such an extent that the greatest patience is required in order to secure any fixed type at all. Let me make my meaning still clearer, if possible.

The first year we start with say, six seeds in the one pod. The second year we have six seedling plants.

The third year we have six rows, short or long, the produce of the six plants of the preceding year, but we also find in each of these six rows Peas of all sorts and types some tall, some dwarf; some early, others later; some large-podded, some small; some pale green in colour, some dark; some curved in the pod, some straight; some pointed at the end, and some square (this difference alone being sufficient in some cases to distinguish two popular garden varieties); and last, but not least, some may be round-seeded, and some wrinkled-seeded. It is clear the selector must commence again, and starting from the most promising plant in each row, endeavour to build up a seedling Pea which will reproduce itself from seed without variation, a task often extending over many years. In scarcely any instance known to me has a seedling Pea been put on the market direct from the hybridiser's hand.

Between 1860 and 1880 many varieties raised by McLean and Laxton were introduced; amongst them being Prince of Wales, Dr. McLean, Omega, William I., and William Hurst, all of which are more or less popular at the present day. During the same period, the first results attained by the

veteran William Culverwell—whose excellent work deserves grateful recognition from all who value Marrowfat Peas—came to light in Telegraph, Telephone, Stratagem, and Pride of the Market, which varieties were introduced by Messrs. Carter. By this time, Henry Eckford was endeavouring, and with considerable success, to infuse the blood of Ne Plus Ultra into a dwarf race of Peas. From various sources appeared during the next few years Autocrat, Duke of Albany (which is certainly one of the most popular Peas of the present day), Sharpe's Queen, Webb's Wordsley Wonder, and others. In 1881 my house introduced American Wonder, which is still more extensively grown than any other early dwarf wrinkled Pea.

I should have preferred on this occasion to have made an allusion to the work of my firm in connection with the Peas, but I think all present will agree with me that no sketch would be complete without referring to the first early wrinkled marrowfat sorts which have been introduced during the past few years, and in the selection of which I have personally been so much interested. I allude especially to My Queen, Al, Empress of India, Seeding, Excelsior, and Forcing, which have attracted so much attention at recent Temple Shows.

Our aim has been to replace the small, hard, round-seeded sorts, upon which the public had been obliged to depend so much for their first supply, with Peas of dwarf growth, but equally as early, and producing pods as large as Telephone, Duke of Albany, and Peas of that class, containing large wrinkled Peas of Marrowfat flavour, and we have succeeded beyond our most sanguine expectations. In Peas of a later class we have introduced other popular kinds, such as Royal Jubilee, Perfection, Windsor Castle, Exhibition Magnum Bonum, Late Queen, and others. The progress with which all these new Peas have been sought after as soon as they have been tried, attests their value, and it is personally gratifying to me to know that Her Majesty—in whose honour we are met to-day—allowed the collection of Peas staged at the Temple Show in 1896 to be placed in the Entrance Hall at Windsor Castle for her personal examination, and that some of the Peas appeared the same evening upon the Royal table. Mr. Thomas perhaps will also allow me to mention that this year Her Majesty was so pleased with the Peas he had grown at Windsor that she telegraphed for a supply to be sent daily by post to Balmoral; and that in June last the Empress Frederick wished seed sent at once to the gardens at Friedrichshof, in order to have Marrowfat Peas in the autumn.

During recent years the list of good Peas has also been added to by such excellent sorts as Daisy, Veitch's Maincrop, Alderman, Laxton's Gradus, and many others.

It may be as well to remark here that the improvement in Peas, as well as other vegetables, has doubtless received considerable impetus from the keen competition upon the exhibition table—a hobby which our older gardening friends seldom if ever indulged in. This competition has likewise had a very marked effect upon the cultivation of Peas and other vegetables; so that, with the fine types now procurable, and the improved systems adopted by growers, results are obtained which are really marvellous.

Before leaving this section, reference must be made to the careful work done in the Chiswick Gardens in making trials of Peas for many years past. The value of these trials, great as it is, would be considerably enhanced did circumstances rendered it possible to grow a larger number of older sorts alongside the new varieties for the sake of comparison. I may mention that in order to make our Peas trials comprehensive enough to determine the value of new seedlings, and to fully test the older varieties offered, &c., it is necessary to sow from 600 to 700 rows annually.

BROAD BEANS.

In the early days of the Queen's reign, lovers of this vegetable were relatively better off than those who preferred Peas, and there already existed such kinds as Marston Dwarf Fan, Early Longpod, and the White and Green Windsor. These have of course been greatly improved upon, but they all remain in use, though it is somewhat surprising that the Marston should be grown at the present time, as in every point it is surpassed by other greatly superior types.

The fact, however, that Beans in use sixty years ago are still grown seems to show that the advance has been less rapid than in the case of many other vegetables. The improvement that has been made is almost entirely the result of selection, although the crossing of Seville Longpod and White Windsor has produced a variety sent out by my house as Giant Windsor, which, as its name implies, is a much larger type of the Windsor section than previously existed.

During the fifties the Seville and the Aquadulce Longpod (very similar sorts) were introduced from the Continent, and on account of their earliness and length of pod have been and still are largely grown, although the constitution of the plant is not nearly so vigorous as our English sorts.

Beck's Green Gem, a sport from the Dwarf White Fan, was introduced in 1848, and some years afterwards the market gardeners in the neighbourhood of Harlington, Middlesex, set to work to improve the Windsor by selection, and as a result of their efforts we have the Harlington White and Green Windsons.

Painstaking selection has done much in the improvement of the Longpod section, the several strains known as Exhibition being fine and profitable types, the best selection of which both white and green-seeded sometimes contain as many as eight or nine beans in a pod, contrasting most favourably with the two or three beans found in the pods of the older kinds. The Broad Bean is not only greatly prized

in private gardens, but is also an important article of food with the poorer classes, and the efforts made to increase its productiveness have been duly appreciated by all classes of society.

DWARF FRENCH OR KIDNEY BEANS.

There were several sorts in use when the Queen ascended the throne, but the difference chiefly lay in the colour of the seed, a feature of little importance except to those who keep a collection of these diversely-coloured and pretty seeds. In fact, they were in the main named after the colour of or markings on the seeds; to wit, the Zebra, Light and Dark Dun, Red and Purple Spotted, Negro, &c., the chief exception being Fulmer's Forcing, which was also in use in 1837. The scope for improvement is limited to size of pod, earliness, and productiveness, and in the former respect, Canadian Wonder, as soon as introduced by us, became very popular; while Ne Plus Ultra, an introduction of more recent date, fairly lays claim to being a marked advance over most sorts for earliness, and also productiveness. Besides these, such excellent varieties as Triumph, White-seed, Forcing, Green Gem, Monster Negro, have appeared, and undoubtedly it may be said that they have come to stay. It was thought that the crossing of this section with the Scarlet Runner might produce useful results; but although many hybrids combining the broad massive pods of the Scarlet Runner, with the habit of the Dwarf Bean, are in the hands of one or two experts, little, if any, advance upon such favourites as Canadian Wonder and Ne Plus Ultra has been made.

CLIMBING FRENCH BEANS.

One of the most notable improvements made in vegetables during Her Majesty's reign has been the creation of an entirely new race of French or Kidney Beans, with a climbing habit of growth. There are several distinct types before the public, differing essentially in the size and colour of the seed, shape and size of pod, and in earliness also. Notable amongst these are our Tender and True and Veitch's Climbing, both attaining a height of 4 to 7 feet according to cultivation; and more recently introduced is our own Excelsior—a Bean combining the delicacy and tenderness of the Canadian Wonder with the vigorous growth of the Scarlet Runner.

RUNNER BEANS

Were represented sixty years ago by the old Scarlet, the Painted Lady, and the Large White, and although one or two sorts of recent introduction are the result of artificial crossing, the majority of the improved types have been attained by selection. But even in some of these cases, it is quite reasonable to suggest that they are natural crosses resulting from inoculation. Scarlet Runners producing pods 12 inches in length would have caused almost as great surprise amongst the gardening fraternity of 1837 as did the advent of the first motor-car in the streets of London. That greater length will yet be attained, I have no doubt, and with it an improvement in quality on some of the existing large-podded kinds. The homely Scarlet Runner which Tradescant cultivated in his garden at Lambeth in the seventeenth century for the sake of its flowers can now, in its improved form, boast of an almost unlimited number of attractive names—each chosen to indicate a type of greater size or length than any previously quoted.

(To be continued.)

OCTOBER 12.—The ordinary fortnightly meeting of this society at the Drill Hall on Tuesday last was remarkably well attended, and the Hall was well filled with exhibits. The most conspicuous feature was that of the perennial Asters, of which there were many good exhibits from the trade and from amateurs. Of Dahlias there was none, but a few Chrysanthemums took the place of these. Orchids were present in considerable quantity. Although the Crystal Palace fruit display occurred so recently, there was plenty of good fruit staged on this occasion, and a Gold Medal was awarded to a collection of Apples and Pears shown by Mr. Woodward, gardener to ROBERT LEITCH, Esq., of Middleton, the only Gold Medal that has been obtained by an amateur for an exhibition of fruit for several years past.

Floral Committee.

Present: Geo. Paul, Esq., chairman; and Messrs. H. B. May, Geo. Stevens, D. B. Crane, J. F. McLeod, Jas. Huison, Thos. Peed, C. J. Salter, J. D. Paw's, Chas. Jeffries, Herbert J. Veitch, J. W. Barr, Jas. Walker, J. T. Bennett-Poole, C. E. Pearson, J. Fraser, Ed. Beckett, R. M. Hog, H. Turner, C. T. Drury, and Ed. Mawley.

Messrs. PAUL & SOY, Cheshunt, had an exhibit composed of Rose-trees in pots, a considerable number of cut flowers, an abundance of hardy flowers, consisting chiefly of perennial Asters and a few herbaceous Phloxes, Pernettyas in several varieties, and Cotoneaster horizontalis in berry were also noticed (Silver-gilt Banksian Medal).

A large exhibit of perennial Asters was one from Mr. F. Beckett, gr. to Lord ALDENHAM, Aldenham House, E. Herts. There were more than eighty large bunches, each of them cut with long stems, and exhibited finely. A. Novi Belgii, varicolor, diffusus, Amellus, polyphyllus, cordifolius, sagittifolius, umbellatus, paniculatus, acris, ericoides, laevis; and numerous varieties of most of these were shown, but the varieties were so exceedingly plentiful, that we have not space even to make a selection. The exhibit, however, was worthy the study of all who desire an abundance of blooms from the open in October. The brightest-coloured variety in

the collection was A. N. B. Orion, a decided and bright pink, the yellow disc being especially bright also (Silver-gilt Banksian Medal).

Mr. W. POTTER, Cam'len Nurseries, Cranbrook, Kent staged a small collection of perennial Asters, in which was included the rubra variety of Aster Amellus. This variety is needed in every collection, as these Asters offer comparatively little of such colour.

Chrysanthemums shown as cut blooms by Mr. Geo. Wythes, gr. to Lord PEACOCK, Syon House, Brentford, were very good. The group was composed of bunches of three good blooms of large flowered varieties, and plants of Adiantum cuneatum were interspersed betwixt them (Silver Flora Medal).

Mr. ROBERT OWEN, Middenhead, showed about two dozen large flowered Chrysanthemums and sprays of some of the newer varieties of Cannas.

That excellent winter-flowering Begonia Gloire de Lorraine, was shown by Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, and Messrs. J. PEAR & SONS, Rouppell Park, Norwood. The groups of plants from Mr. MAY presented the variety in its best possible condition, as serviceable plants in 5-inch pots, each abundantly flowered, and perfect specimens (Silver Flora Medal). Messrs. PEAR'S plants were smaller, some of them in 3-inch pots, but they bore numerous flowers.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, Chelsea, showed a cut a dozen plants of Vitis Colquhouni that has been described many times in these columns, and some plants of Vitis vulpina purpurea bearing very much smaller foliage, coloured intensely purple. Crataegus orientalis in fruit was shown as sprays. The exhibit also included several plants in flower of Caryopteris mastacanthus (Gardeners' Chronicle, vol. xxi., 1884, p. 149). Messrs. VEITCH had a group of plants of their Javanica jasminiflorum hybrid Rhododendrons, all the flowers being very attractive. The same firm obtained an Award of Merit for a very pretty variegated Veronica named Silver Star, and also exhibited a fine large plant of Divallia Cheloni, plants of Cornus sanguinea atrosanguinea with darker coloured leaves than the type; a specimen of Cedrus Deodara aurea, and several plants of Nandina domestica, a pretty plant with compound red leaves (Award of Merit).

An exhibit of perennial Asters by Messrs. JAMES VEITCH & SONS differed from the rest, by the fact that the plants had recently been lifted from the open ground and put into pots. It was therefore possible to see the habits presented by the entire plants, and the circumstance further showed how suitable are perennial Asters for lifting, to be used as decorative plants indoors. The group included about sixty plants in thirty varieties, which had been chosen to represent distinct types (Silver-gilt Banksian Medal).

Crotons were exhibited by Messrs. B. S. WILLIAMS & SON, Upper Holloway, London, who had about fifty plants of moderate height arranged upon one of the tables (Silver Flora Medal).

Ten Roses were shown very tastefully by Mr. GEO. FAIRCK, of the Oxford Nurseries (Silver Banksian Medal).

A group of berried plants from Messrs. W. CURNISH & SON, Highgate, London, N., included a lot of plants of Crataegus Pyracantha Lelandi, Orange trees in fruit; and a band of plants of Skimmia japonica encircling the other plants was effective.

SIR TREVOR LAWRENCE, Bart., Burford, Dorset (gr., Mr. Bain), exhibited a group of a dozen plants of tuberous Begonias with fringed flowers, similar to the one figured in the Gardeners' Chronicle, p. 63 in present volume. An Award of Merit was recommended to the strain.

A hybrid Sarraacenia was shown by Mr. J. T. BENNETT-POLE, obtained from a cross between S. fissa and S. purpurea, and raised at the Glasnevin Botanic Garden.

Mr. H. DEVERALL, of the Banbury Nurseries, staged a group of perennial Aster flowers, and several varieties of Holenium and Rudbeckia. The Asters included A. varicolor, a very dwarf growing plant, with small but pretty flowers. A. acris, W. Bowman, a new British var. of high colour; and one called Madonna, an improvement on Harpur Cress; besides the pretty laevigatus, diffusus, &c.; Chrysanthemum uliginosum with its large white flowers was also included.

Mr. HARRIS BOWDEN Hill House, Chippingham (gr. Mr. J. Penton), exhibited sixteen bunches of Violet Tricolor.

Mr. W. BULL, 516 King's Road, Chelsea, showed a few plants of the new Maranta picta, with leaves about 9 inches long and 3 inches wide, each leaf light pea-green and dark velvety-green in colour, and the plants compact in habit (Award of Merit).

Mr. EMPSON, gr. to Mrs. WINGFIELD, Amphill House, Amphill, showed half-a-dozen plants of a good decorative Chrysanthemum with bluish coloured flowers, and named Mrs. Wingfield (Award of Merit).

Mr. W. WELLS, Earswood Nurseries, Rehill, Surrey, showed several new varieties of Chrysanthemums as plants.

Mr. W. J. GODFREY, Exmouth Nurseries, Devon, exhibited about two dozen and a half of Chrysanthemum blooms, including several well-known varieties. An Award of Merit was recommended to the Chrysanthemum Madame G. Bruant, a Japanese variety of much merit, flowers very long, white towards base, becoming light purple towards end, shown by Messrs. J. R. PEARSON & SONS, Chilwell, Nottingham.

Messrs. HAWKINS & BENNETT, Twickenham, exhibited a group of zonal Pelargonium Duke of Fife, a semi double dark scarlet flower produced on strong long stems.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. Jas. O'Brien (Hon. Sec.), B. Courtauld, W. H. Protheroe, W. Cobb, E. Hill, W. H. Young, F. J. Thorne, H. Williams, H. J. Chapman, De B. Crawshaw, T. W. Boud, H. M. Pollett, and T. B. Haywood.

Messrs. JAS. VEITCH & SONS, Ltd., Royal Exotic Nursery, King's Road, Chelsea, were awarded a Silver-gilt Flora Medal for a magnificent group of rare and beautiful Orchids, including many new and rare hybrids, among which were the fine Sibrallia x roseo-macrantha, a plant which is of dwarf habit, and possesses purplish rose-coloured flowers of large size, whose sepals and petals have a white margin; Lælio-Cattleya x Lucilia (L.C. elegans x C. Dowiana), with pale rose-tinted sepals and petals, lip of a rich purple-crimson hue, and a yellow disc; the new Dendrobium taurinum ambolense, with growths imported, some 6 feet in length, and carrying ascending spikes of numerous flowers, in form resembling those of the type, but of a yellow colour on the reverse side of the flower, the face being reddish-brown (Botanical Certificate). Other fine hybrids represented were the Lælio-Epiphronitis x Veitchi, Lælio-Cattleya x Pallas, L.C. x Nysa, and its varieties superba and purpurea; L.C. x Eudora, L.C. x Novelty, Cattleya x Caloria, C. x Eros, Cyrtopodium x Drurio-Lawrenceana, C. x Arete, C. x Arthurianum, C. x Genanthum superbum, &c.

The rear plants in the group consisted of Oncidium phytostichum, of very slender growth; O. divaricatum, O. Forbesii, O. pretextum, O. varicosum, O. tigrinum; fine specimens of the singular-looking Dendrobium stratosi; D. Pinnatifidum Schrodorianum, Odontoglossum Uro-Skinneri splendens; the white-lipped O. Buteonense album; O. grande, handsome varieties of Cattleya labiata; Vanda Sanderiana, Angrecom Challuianum, and A. citratum; the orange-carlet-coloured Dendrobium subulatum, Cyrtopodium insignis Sanderi, and the true O. purpuratum; Compactia coccinea, Lonicera paniculata, and other rare species of small growth. An example of Coelogyne Veitchi bearing six spikes, varying from thirty to thirty five of its white flowers on each spike, was an attractive object.

R. I. MEASURES, Esq., Cambridge Lodge, Camberwell (gr. Mr. H. J. Chapman), was awarded a Silver Flora Medal for an effective group that consisted principally of forms of Cattleya labiata, and included a plant of the remarkable C. labiata "R. I. Measures," which has charming white flowers, with a delicate pink veining on the front of the lip; Lælio-Cattleya x Sallieri (L. purpurea var. x C. Loddigiana) with several very pretty light rose flowers on a spike; fine examples of Lælia pumila, a grand specimen of Dendrobium aureum; the richly-coloured Cyrtopodium x Chapman; and other hybrid Cyrtopodiums, the most remarkable of which was C. x callosa Mastersianum, with singularly-tinted, wax-like flowers, formed part of the exhibit.

SIR TREVOR LAWRENCE, Bart., Burford, Dorset (gr. Mr. W. H. White), showed a fine specimen of Cryptophranthon Dyanus, bearing a number of its singular-looking flowers, which resemble a hawk's head (Botanical Certificate).

Messrs. HUGH LOW & CO. Clapton, were awarded a Silver Flora Medal for an effective group, in which were fine varieties of Cattleya labiata, arranged with C. Loddigiana, C. Dowiana, good varieties of Lælia pumila, among which was L. pumila, "Low's var.," with blue-purple-tinted flower, bearing a great resemblance to the Gattion Park variety, certificated at the last meeting, received an Award of Merit. The group also contained plants of the fine yellow-coloured Cyrtopodium insignis Laura Kimball, and C. insignis W. Mittle Dow; also the handsome C. x Mrs. Tautz, C. x William Lloyd, and other hybrids; fine examples of Odontoglossum grande, O. crispum, Dendrobium Phalenopsis violaceum, Oncidium oithorhynchum album, O. Lanceanum, &c.

Messrs. B. S. WILLIAMS & SON, Upper Holloway, staged a pretty group, which secured a Silver Banksian Medal, in which were remarked several Cattleya labiata in variety, including gloriosa and purpurea; Cyrtopodium x giganteum, Williams' variety (Sallieri aureum x Harrisonianum superbum), C. x Pictorianum, Williams' var., C. x onanthum, O. Chamberlainianum, Paetores Lehmanni, Saccolabium Blumei, Odontoglossum cristatum, O. Wallisii purum, O. constrictum, Dendrobium bigibbum, D. Phalenopsis, Cochlidia vulcanica, &c.

Messrs. F. SANDER & CO., St. Albans, exhibited several beautiful varieties of Cattleya labiata, including a white form with purple blotch on the lip; C. x Mrs. (labiata x Lawrenceana), Bulbophyllum Godeffmanum, Cattleya Bowringiana, &c.

HIS GRACE THE DUKE OF WESTMINSTER, Eaton Hall, Chester (gr. Mr. N. F. Barnes), sent an attractive, dark-coloured variety of Dendrobium Phalenopsis Schrodorianum.

Mr. T. ROCHFORD, Turnford Hall Nurseries, showed a plant of the remarkable Vanda cœrulea Rochfordiana, a variety possessing clear white flowers, and a lip of a soft pink tint (Award of Merit).

H. T. PITT, Esq., Roslyn, Stamford Hill, showed Odontoglossum grande Pittianum, a fine clear yellow form, in which the brown bars seen in the type are suppressed (Award of Merit).

Mr. J. W. MOORE, Eldon Place Nursery, Bradford, exhibited Vanda x Moorei, a natural hybrid between V. Kimballiana and V. cœrulea, between which species it is intermediate in character. The flowers were larger than V. Kimballiana, and the lip longer and narrower; the sepals and petals are of a lavender-blue colour; the side lobes of the lip brown, and the blade purple-coloured (Award of Merit).

WALTER COBB, Esq., Dulcote, Tunbridge Wells (gr., Mr. J. Howes), sent *Zygopetalum foristanum* (*Lindleya* v. t. 93), a pretty and floriferous species for which an Award of Merit was made; also *Cypripedium Charlesworthii*, Dulcote variety, in which the upper sepal is variegated with white and rose.

C. L. N. INGRAM, Esq., Elstead Hall, Godalming (gr., Mr. T. W. Bond), again showed the pretty *Cattleya* × *Eclipse* (maxima × Skinneri), for which he had previously received an Award of Merit; the singular-looking *Laelio-Cattleya* × *Firefly* (*L. Dormaniana* × *C. Bowringiana*), with dull rose flowers and elongated lip; *L.-C.* × *illustris* (*L. Dayana* × *C. Warscewiczii*), which resembled *L.-C.* × *Epicasta*; and *L.-C.* × *olorata* (*C. Eldorado* × *L. xanthina*), a neat yellowish-white flower, with markings of rose upon the lip.

J. BRADSHAW, Esq., The Grange, Southgate (gr., Mr. H. Whiffen), showed a fine plant of *Cattleya* × *Mantini nobilior* (*Bowringiana* × *Dowiana aurea*).

J. W. TEMPLE, Esq., Leyswood, Groombridge (gr., Mr. C. Bristow), showed *Laelio-Cattleya* × *Templaris*, of unrecorded parentage, which much resembled *Cattleya* × *Minucia* (*Lodigesi* × *Warscewiczii*). H. J. HARRIS, Esq., J.P., Bowden Hill House, Chippenham (gr., Mr. J. Penton), sent a very fine form of *Odontoglossum grande*. F. W. MOORE, Esq., Royal Botanic Gardens, Glasnevin, Dublin, sent *Nanodes Mantini* (Botanical Certificate) and *Maxillaria punctatostriata*.

Fruit Committee.

Present: Philip Crowley, Esq., Chairman; and Messrs. Hugo M. Müller of Vienna, Geo. Bunyard, Jos. Cheal, G. W. Cummins, W. Pope, A. H. Pearson, A. F. Barron, Alex. Dean, J. W. Bates, G. Woodward, James H. Veitch, J. Willard, J. Smith, Geo. Wythes, F. Q. Lane, G. Reynolds, W. J. Eapson, R. Fife, and T. J. Saltmarsh.

The Gold Medal of the Society was awarded to Mr. G. Woodward, gr. to ROGER LEIGH, Esq., Barham Court, Maidstone, for a magnificent display (100 dishes) of Pears and Apples. When we say that the fruits were as fine examples as it is possible to grow in this country, we are saying no more than is undeniable. Many of the varieties were shown by the exhibitor at the Royal Horticultural Society's show, held at the Crystal Palace at the beginning of the month.

Mr. A. H. RICKWOOD, gr. to Dowager Lady FREAKER, Fulwell Park, Twickenham, showed ninety-six dishes of Apples and Pears of average merit, securing a Silver Banksian Medal. Some few of the newer varieties of Pears and Apples were noted in this collection, but old varieties formed the greater proportion.

The second-best collection of Apples and Pears at the meeting was that shown by Mr. A. Offer, gr. to J. WARREN, Esq., Handcross Park, Crawley; this comprised many fine examples of Pears, but was weak in Apples, as compared with the Barham Court collection, although colour, as is usual in Sussex Apples, was brighter than was observed in the Kent fruit. An award of a Silver Knightian Medal was made.

A collection of bottled fruits came from T. GRAHAM POWELL, Esq., Horticultural College, Swanley. There were included two or three varieties of Cherries; Gooseberries, Pears, and black Currants. Ordinary bottles, with sealing-waxed corks, were used.

In the competition for flavour in Pears, the 1st prize was given to Thomson's Pear, shown by Colonel BRYMER, Islington House, Dorset (gr., Mr. J. Powell); 2nd prize to Rev. H. GOLDING PALMER, Holm Park, Berks (gr., Mr. Osborne), for Marie Louise.

In Apples, Mr. G. WOODWARD, gr., Barham Court, was 1st, with Cox's Orange Pippin; and Colonel BAYMER was 2nd, with Ribston Pippin.

Messrs. G. BUNYARD & Co., Maidstone, received an Award of Merit for Apple, Jas. Grieve, an early, pleasantly flavoured dessert fruit.

JOHN ESTER, Esq., Wakefield, showed a small collection of Apples, chiefly culinary varieties, and of fair quality, obtaining a Silver Banksian Medal; fifteen dishes in all.

Mr. THOMAS ROBERTSON, gr., Elsfeld, Notts, showed Runner Beans of large size, and almost straight.

Messrs. A. W. YOUNG & Co., nurserymen, Stevenage, showed a pretty collection of ornamental Gourds in perhaps a score of different species, and apparently in well ripened condition. These are interesting plants wherewith to cover rough fences in gardens, and are too seldom grown or shown.

Messrs. J. CARTER & Co., 237 and 239, High Holborn, showed a representative collection of agricultural and culinary varieties of Cabbage, and among them we remarked good examples of the Magdeburg, a drum-head variety suitable for making sauerkraut or feeding cattle; Early Heartwell, extra good; Red Utrecht, an early hearting sort; Winnigstadt, an old conical-shaped Cabbage of nice flavour; Hardy Green Colewort, one of the best for general planting for winter use; All Seasons, a fine-looking Drum-head; Wheeler's Imperial, still one of the best when true; Rosette Colewort, good for close planting in gardens, and very hardy; Jersey Wakefield; Garfield Red, an early hearting small variety; Nonpareil, a miniature Drum-head; Mammoth Beef-heart, the old well-known St. John's Day, and others.

Lecture.

SOME CURIOSITIES IN ORCHID BREEDING.

This was the title of a very long and exhaustive lecture delivered in the afternoon by Mr. C. C. HURST. In commencing the subject, Mr. Hurst said that to better understand certain abnormal results attending the crossing of Orchids, it would be well first to study the normal effects. Hybrids of the first generation, that is between two distinct species, were

generally exactly intermediate in character between the parents. Such an instance was *Cypripedium Leeanum* ×, which was intermediate between *C. insignis* and *C. Spicerianum*. From such a cross the whole of the seedlings would be *C. Leeanum* ×, and as often as the cross was effected this would be the result, whether or not *Spicerianum* or *insignis* were used as the pollen-parent. There would be varieties of *Leeanum* ×, but these would not differ from each other in greater degree than varieties of a true species. It was very necessary then that any hybrids of a certain cross should be known by one specific name only, and to distinguish certain forms from others, varietal names only should be used. It was also found that the varieties occurring in such a cross were limited in number, if neither of the parents had many varietal forms. Of *C. Leeanum* × there were innumerable varieties, but so there were of *C. insignis*, one of its parents. The result of a cross would also depend upon the varieties used of the parent species. *C. Spicerianum* crossed with *C. insignis* Sanders produced a well-known variety of *C. Leeanum*.

C. insignis Chantini crossed with itself produced a lot of varieties, proving that the parent had not been fixed for any length of time. In speaking of the "reverse" cross, it was admitted that sometimes the varieties differed from those obtained from the original cross; but, as proved by Messrs. Veitch, in the case of *Cypripedium Sedeni*, they are not intrinsically different. If the seedlings were different, then the varieties of the species used for the parents were not the same; or if the same varieties had been used, then they have had a "past."

The lecturer proceeded to describe the whole process of pollination and fertilisation, and referred to the study and observations of Mr. Harry Veitch into the pollination and fertilisation of *Cattleya Mossii*, the results of which were contributed in a paper read before the Linnean Society about ten years ago. The process of fertilisation was described in order to show why a cross from distinct species should be intermediate between the two parents. The subject of nuclear sub-division and of male and female organs, and the confluence of the two, which results in the destruction of exactly one-half of the nuclei possessed by either, and therefore the union of an equal number of each, is a decidedly abstruse subject, but one the study of which by experts may be expected to throw light on many of the phenomena of hybridisation and sporting.

Mr. Hurst next proceeded to cite eleven cases where the seedlings from a cross had resembled one parent only, and discussed if such could possibly be true hybrids. He thought they were not, but had been fertilised by their own pollen, or fertilisation had occurred without any pollen reaching the ovule at all. The above was referred to as one of many curiosities of hybrids of first crosses. Owing to want of time, Mr. Hurst was obliged to treat a good deal of the paper "As read." Referring to *Odontoglossum* hybrid seedlings, the result of these in some cases had been to determine the parents of natural hybrids, already in cultivation. The influence of foreign pollen was considered, and in regard to the ripening of seed pods, it was said that the nearer to midsummer the cross was effected, the sooner did the pod ripen. Mr. Hurst went on to consider generic hybrids and certain curiosities attending such crosses. Twenty-six different genera had been united together by fertilisation, and a diagram was shown indicating in what manner and to what degree this had been done. The fertility of hybrids between species, and other aspects of this question were considered. The sterility of hybrids was attributed to the male element in the hybridising. The paper dealt with other matters, and was a most elaborate one, which can be better studied when it has appeared in the society's *Journal*. Mr. H. J. Veitch occupied the chair, and after the reading of the paper, Mr. R. A. Rolfe, of Kew, discussed many of the statements that had been given, from some of which he differed.

BEDDINGTON AND CARSHALTON HORTICULTURAL.

OCTOBER 5. — The annual general meeting was held on the above date at Carshalton. From the report of the committee it was shown that the society's exhibition was this season a moderate success.

The total number of entries for competition was equal to that in previous years, and there were many honorary exhibits of high quality. Owing to the Diamond Jubilee celebrations, and the consequent appeal for subscriptions for other causes, there was, as the committee expected, a slight falling off in the subscriptions and donations to the society during the year, but notwithstanding this there was a balance in hand of over £53. A conference was held on gardening, at which Mr. A. H. SMEE, C.C., presided. It was a decided success, and a large audience manifested the closest interest in the addresses.

The balance-sheet showed that the year was commenced with a balance in hand of £35 18s. 10d., subscriptions, donations, and special prizes amounted to £138 10s. 6d., the various receipts in connection with the show on Bank Holiday amounted to £158 17s. 3d., and the Sports Committee returned £2 2s. 2d., making the total receipts £335 14s. 9d. There was paid in prizes £97 15s. 6d., and a sum of £30 18s. was voted to the Sports Committee, the total expenses of the year amounting to £282 7s. 3d., leaving a balance of £53 7s. 6d.

Mr. H. Cosmo Bonsor was elected President, and Mr. S. Stewart a Vice-President of the Society.

Mr. G. W. CUMMINS was renominated for secretary, but stated that as he had given up his appointment as gardener at the Grange, it was with the greatest regret he had to decline the honour and resign the position he had held from the commencement of the society.

The chairman and others spoke of the able way in which the duties of the secretary had been conducted; and a vote of thanks was heartily passed, as was also a resolution that an honorarium of ten guineas be awarded Mr. Cummins in recognition of his services.

Mr. Cummins, in returning thanks, said that as long as he remained in the district, the Horticultural Society should have his hearty support.

Mr. W. T. TOOGOOD (late assistant secretary) was then elected secretary, and Mr. C. F. F. HUTCHINGS assistant secretary.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

OCTOBER 7. — Present: G. Shorland-Ball, Esq., in the chair, along with Messrs. Jas. Backhouse, Wm. Bolton, R. Johnston, H. Greenwood, Captain Schofield, Wm. A. Gent, and Jas. Anderson.

This was by far the best collection of good showy Orchids, combining some sterling varieties, that has yet passed before the Orchid Committee of the North of England.

The exhibit of *Dendrobium* by Mr. R. Johnson, gr. to THOS. STATTER, Esq., Stand Hall, Whitefield, covered with at least 2000 blooms, worthily gained the award of a Silver Medal. The same honour was granted to GEO. SHORLAND-BALL, Esq., of Ashford, Wiltshire (gr., Mr. A. Hay), who had a *Cypripedium insignis* Harefield Hall var. (F. C. C.), flower very large in all its parts, and of clean, clear captivating colour. Other honours fell to the same exhibitor for *Cypripedium Memoria Mensii*, still the finest red *Leeanum* we have, and to *C. tonsum giganteum* (Award of Merit).

Alderman BOLTON, Wilderspool (Mr. Cain, gr.), showed a grand lot of plants in fine bloom; and his *Cattleya* resembling *C. Hardiana*, and named *C. Massaiana Boltoniana*, with four magnificent flowers, an outcome of natural hybridisation, will long be remembered, the crimson on the lip, and the cerise tint of the segments of the flower, making it most attractive; the committee awarded it a First-class Certificate. His varieties of *Cattleya Harrisoniana* were choice and varied in colour. These were hybrids, either natural or artificial, which showed how interesting cross-breeding becomes in capable hands. These three varieties received the award of a Silver Medal each, in consideration of their beauty and the high degree of culture exhibited.

Next in importance to the above was the collection from HUGH LOW & Co., London, and nothing was better than the *Cattleya aurea*, Mrs. Gratrix, which obtained a First-class Certificate. Along with this plant was *Cypripedium insignis*, Nellie Don (Award of Merit) *Cattleya* × *Nyssa splendens* (Award of Merit), had the handsomest lip we have yet seen.

By far the finest-grown plant on exhibit was the *Vanda cœrulea* from JAMES BACKHOUSE & SON, York. The plant had nearly one hundred open flowers upon it. An Award of Merit and Cultural Commendation were given.

JOHN LEEMAN, Esq., West Bank House, Heaton Mersey (Mr. Edge, gr.), had several good *Cypripediums*; and a form of *Cattleya Hardiana*, which the committee asked to be shown again.

O. O. WRIGHT, Esq., Bury, and several other gentlemen were awarded thanks of the Society.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

OCTOBER 12. — The annual dinner of this society was held on Tuesday evening last at the Holborn Restaurant. Mr. H. B. MAY, of the Edmonton Nurseries, presided over what was probably a "record" attendance. On such a busy day as Tuesday proved to be, such an attendance was a testimony to the very lively interest taken in the welfare of the society; an interest justified by the praiseworthy aims of the institution, existing as it does for the purposes of assisting gardeners in sickness and old age.

The chair was well supported by a goodly number of influential representative horticulturists. When the toast of Her Majesty the Queen had been received with musical honours, the chairman rose to propose that of the United Horticultural Benefit and Provident Society, which was accompanied by a short but sensible speech.

The Chairman remarked that had those present been unassociated with gardening, it might have been necessary to speak of the difficulties attending a gardener's career, the uncertainty of employment, the ills to which they are subject from climatic changes, and the inability which too frequently precludes them from making provision for that time of which Longfellow sings:—

"The common fate of all,
Into each life some rain must fall;
Some days must be dark and dreary."

In the presence of gardeners this, however, was unnecessary. The society had for its motto, "Unity is strength," but it was also founded upon the basis of self-help. It was democratic in its constitution, and the substantial progress made was a brilliant testimony of its appreciation by those for whose benefit it was established. It was founded by gardeners, is conducted by gardeners, and was

for the welfare of gardeners; and the advantages it offers its members, especially its aged members, was most liberal—a happy combination of a benefit society and a savings-bank. The rates of contribution and benefits were then given, and reference made to the rule of the society to keep the funds of lapsed members until they reach the age of sixty, and then return it to them with compound interest, or, in case of death, it is immediately given to the deceased's nominee. The concluding paragraph in the actuaries' report at the quinquennial valuation in 1896 was read, and from this it became evident that there had been an increase of membership in the time from 191 to 535, the growth of funds from £4,933 to £9,533, and an increase of income from £908 to £1,376.

The Chairman, after expressing his intention to become a honorary member, appealed to others to assist the funds in a similar manner. Alluding to the Benevolent Fund initiated by Mr. N. N. Sherwood, the Chairman justly congratulated the members upon this feature of the Society, that helped convalescent members at a time when help was exceedingly useful.

In reply to this toast, Mr. J. Hudson, Hon. Treasurer to the Society, made several satisfactory statements, including one to the effect that it was expected the Society would invest during the present year £1300, or £100 per month. He spoke of the increased number of members, at the same time inviting more, and basing his plea upon the economical method by which the Society is managed. Incidentally it was said that no committee meeting was held in course. Any member might be present at any meeting he wished. The present membership was 684.

Other toasts included "The Honorary Life Members and Visitors," responded to by Mr. Geo. Bunyard and Mr. B. Wynne, "The Chairman," "Kindred Institutions," a toast that afforded Mr. G. Ingram an opportunity to plead the cause of the "Gardeners' Royal Benevolent Institution." A tribute of praise is deserved for the tasteful manner in which the room and tables were decorated, and the proceedings generally were characterized by enthusiasm.

Mr. Geo. BUNYARD has accepted an invitation to preside on the occasion of the next annual dinner.

NATIONAL CHRYSANTHEMUM.

OCTOBER 12, 13, 14.—The usual October exhibition of Chrysanthemums by this society, being the second held this season, was opened on Tuesday last in the Royal Aquarium, Westminster. In the open classes for twenty-four and for twelve blooms of Japanese flowers, there was much competition, and the quality of the blooms was good, particularly the 1st and 2nd prize collections of twenty-four blooms. Apart from these classes, the competition was only moderate, and in two or three instances there were no entries. Pompons were few and poor, and the exhibition was practically one of Japanese varieties only. The groups of Chrysanthemum-plants were commendable. Table decorations and epergnes of Chrysanthemum blooms made much display.

There were three groups of Chrysanthemums and foliage plants, each upon a space of 73 superficial feet. The 1st prize was won by Mr. NORMAN DAVIS, Framfield Nurseries, Sussex. In this group, the Chrysanthemums were good; and more than that, they were freely interspersed with plants of an ornamental character, the intermixing being effected with much taste. Among the Chrysanthemums, the varieties Louise, Perle Dauphinoise, Mrs. S. W. Palmer, Ethorne Beauty, and Geo. Seward showed best. The 2nd prize went to Mr. Howe, gr. to H. Tate, Esq., Streatham Common, S.W., who also very freely supplemented the Chrysanthemum with choice foliage plants. 3rd, Mr. J. H. WITTY, Nunhead Cemetery.

In the class for twenty-four blooms, Japanese (open), there were seven competitors, and the winning stand of Mr. C. Penfold, gr. to Sir F. Fitzwarren, Bart., Leigh Park, Havant, contained blooms as large in size as many that are usually staged in November. The largest blooms in this case were put in the front row, rather than at the back. It contained no absolutely new varieties, but many of last year's novelties were shown. Thus there were Modesty, Mutual Friend, Mdle. Chenon de Leche, Edith Tabor, Madame Gustave Henry, International, and others. Mr. JAS. AGATE, nurseryman, Havant, took 2nd prize, with smaller but better coloured flowers, than the others. For instance, Mons. Chenon de Leche, Ed. Molyneux, Milano, and Surprise were capital. 3rd, Mr. NORMAN DAVIS, The Vineries, Framfield, Sussex. There were also two extra prizes awarded.

For twelve blooms Japanese, distinct (open), Mr. F. G. Foster, Brockhampton Nurseries, Havant, beat five other competitors, his best blooms being Edith Tabor, Mutual Friend, and Phœbus; 2nd, Mr. R. Jones, gr. to C. A. SMITH-BLYNDEN, Esq., Barford Hill, Warwick; Mr. JAS. AGATE was 3rd. The flowers generally in this class were rather weaker in quality than those in the previous one.

In the amateur's class for twelve blooms of Japanese, distinct, there were two exhibitors, the 1st prize being taken by Mr. R. Gladwell, gr. to SYDNEY SMITH, Esq., Wenden Hall, South Norwood. Mutual Friend, Phœbus, and G. C. Schwabe were the best in a satisfactory dozen blooms. This same exhibitor had 1st prize for six blooms also, beating two other exhibitors. All of these blooms were good. They were Phœbus, Edwin Molyneux, President Borel, Mrs. C. H. Payne, Mutual Friend, and G. C. Schwabe.

The amateur class for twelve blooms in six varieties, was won by Mr. MARTIN SILSBURY, Shanklin, Isle of Wight; and Mr. HENRY LOVE, from Sandown, also in the Isle of Wight, was 2nd. Mr. M. SILSBURY won the class for six blooms, distinct.

The best table of bouquets, wreaths, &c., was adjudged to be one shown from Mr. CHARD'S Establishment, Stoke Newington.

Mr. Jas. Brookes, gr. to W. T. NEWMAN, Esq., Totteridge Park, Herts, won a 1st prize for two vases furnished with Chrysanthemum blooms, for which there were five competitors; and Mr. T. Thillett, gr. to G. ALEXANDER, Esq., Warley Lodge, Brentwood, had the best single vase.

The best three epergnes of Chrysanthemum flowers were those from Mr. D. B. CRANE, Archway Road, Highgate, 2nd, Mr. C. B. COLE, The Vineyard, Feltham. The epergnes from Mr. CRANE were novelties. The glasses at various heights were secured to the top of stiff wires, the other end of the wires being let into a comparatively insignificant-looking stand made of wood. The wires may be taken out, glasses removed, and the whole packed for travelling with little trouble. If a heavier, better stand be substituted, this form of epergne will possess many advantages.

Pompons were represented but badly. The 1st prizes for twelve and for six bunches were taken by Mr. E. F. SUCH, of Maidenhead.

NON-COMPETITIVE EXHIBITS.

The largest non-competitive collection of Chrysanthemum blooms was that from Mr. W. J. GODFREY, Exmouth, who had upwards of ten dozen blooms. A dozen blooms of Viscountess Roger de Chazelles, Japanese yellow, were very fine. Many of the newer varieties were well shown, and a few novelties. Carnation blooms in sprays made part of this exhibit.

Mr. T. S. WARR, Hale Farm Nurseries, Tottenham, furnished a table with Adiantum Ferns, which were studied with Chrysanthemum bloom, Tritoma blooms, Nerine varieties, &c. From Tottenham there was also a group of hardy flowers for the greater part consisting of perennial Asters.

Mr. W. WELLS, Earlswood Nurseries, Redhill, had what would have been a circular group of Chrysanthemum plants, but for four tables at equal distances in the circumference. Upon these were placed cut blooms of Chrysanthemums, of comparative novelties, the blooms being capital in quality for this date in October. The group included a plant bearing three blooms of the new Japanese variety Madame G. Bruant described below. Altogether the exhibit was a showy one, and it obtained a Gold Medal.

Messrs. H. CANNELL & SON, Swanley, had a group of Gladioli in bloom, and a small collection of excellent Chrysanthemum blooms. Amongst the latter we noticed the large yellow Japanese Soleil d'Octobre, Milano, and others were well shown, and the same firm had good Onions and other vegetables.

Mr. E. F. SUCH, nurseryman, Maidenhead, showed bunches of blooms of early-flowering Chrysanthemums cut from the open.

Mr. H. J. JONES had his exhibit arranged upon a table. It consisted of Chrysanthemum blooms of early and late varieties interspersed with Ferns. Zonal Pelargoniums in sprays were also included.

Mr. H. Berwick, Sidmouth Nurseries, Devon, made a display of Apples and Pears, as did also Messrs. S. SPOONER & SONS, Hounslow Nurseries, Middlesex. Messrs. JNO. LAING & SONS, Forest Hill Nurseries, London, S.E., had a collection of Apples and Pears, in addition to perennial Asters, and other hardy flowers, fibrous-rooted Begonia plants, &c.

AWARDS TO NOVELTIES.

A First-class Certificate of Merit was awarded to Japanese Madame G. Bruant, a large full drooping petalled flower, with a deep suffusion of purple towards the points of the petals. This fine variety was also shown by Mr. WILLIAM WELLS, but his blooms were not so finely developed as those of Messrs. PEARSON & SONS, Chilwell, Nottingham, it being a rule of the National Chrysanthemum Society that the certificate should go to the best blooms. The same award was made to a decorative variety named Ambrose Thomas, from Mr. W. WELLS, having orange thread-like florets, a very free-flowering and attractive October-blooming variety. Several other new varieties were staged, but not sufficiently developed to judge of their actual value.

Obituary.

JESSE KERSEY SHARPLESS.—On September 10, last, there died at Catawissa, in Pennsylvania, U.S.A., in the 81st year of his age, Jesse Kersey Sharpless, an American gardener, and the raiser of the valuable prolific-bearing Strawberry Sharpless.

MR WILLIAM SCOTT.—As we are going to press we hear of the death at Stirling, on the 3rd inst., of Mr. William Scott, Director of the Mauritius Botanic Garden. In our next issue we hope to give some account of his career.

MARKETS.

COVENT GARDEN, OCTOBER 14.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending October 9, is furnished from the Meteorological Office:—

"The weather during this week was fair and dry over the kingdom as a whole; rain, however, occurred frequently over our extreme northern and north-western districts, especially at the coast-stations, and the fall extended on one or two occasions to many other parts of the kingdom.

"The temperature was considerably below the mean over England; it just equalled the mean over Ireland and in 'Scotland, E.' and slightly exceeded it in 'Scotland, N. and W.' The highest of the maxima were registered, as a rule, on the 3rd, and ranged from 69° in 'Scotland, N.' to 65° in 'Scotland, E.' and to 60° in 'England, N.E.' the 'Midland Counties,' and 'Scotland, W.' The lowest of the minima were recorded about the middle part of the period, when the thermometer in the screen fell to 28° in the 'Midland Counties,' 39° in 'England, E.,' and 31° in 'England, S.W.,' to 35° in 'England, N.E.' and 'Ireland, S.,' 38° in 'England, N.W.,' and to 41° in the 'Channel Islands.' Over the inland counties very sharp frost occurred on the grass. Both at the beginning and end of the week the minimum values were considerably higher.

"The rainfall just equalled the mean in 'Scotland, N.' but was much less in all other parts of the kingdom. Over all the eastern and southern parts of Great Britain the fall was very slight.

"The bright sunshine varied a good deal in different parts of these islands, but was in excess of the mean in most districts. The percentage of the possible duration ranged from 55 in the 'Channel Islands,' 52 in 'England, S.,' and 49 over the 'Midland Counties,' to 28 in 'England, N.E.,' 25 in 'Ireland, N.,' and 21 in 'Scotland, N.'"

NOTICES TO CORRESPONDENTS.

AMARYLLIS BELLADONNA: Amateur. The fertilising-moss is scarcely adapted for Amaryllis in general, although the so-called Guernsey Lily may flower well in it; but then these bulbs arrive in this country with well-advanced flower-spikes, and these would be produced if the bulbs were not potted at all. A. Belladonna should be potted or top-dressed in February with rather heavy loam, a small quantity of sand, and finely-broken charcoal, potting the bulbs firmly in pots not greatly larger than the bulbs. Let one-third of the bulb be above the level of the soil when the surface is

finished off. At the first, the warmth may be about 60° by day, and 55° by night; and as the season advances, the heat may be increased slightly. When growth is complete, the season has advanced considerably, and artificial heat becomes unnecessary. Soon after this the leaves decay, if water be withheld, as it should be; and towards the end of June root-activity begins again, and in autumn the flowers appear, but no leaves, these coming later. This species does well out-of-doors, at the foot of a south wall, planted 6 or 8 inches deep in well-trenched soil; and if sandy-loam can be provided for the bulbs, so much the better.

ASSOCIATION: R. Quinn. The Nursery and Seed Trade Association, 30, Wood Street, Cheapside; Secretary, Mr. S. Worrell.

BOOKS: "CORK TREES." W. J. We are also unable to trace any notice of the book in question.

CARNATION: Mrs. R. Your plants are affected with the Carnation-spot. Burn all the affected leaves. Next year spray the young foliage once or twice in the season with weak Bordeaux Mixture, or Condy's Fluid, as a preventive.

COCOS NUCIFERA (COCO-NUT PALM): Coco-nut. The plants are worth about 10s. a piece if in good condition.

COLOURING OF THE LEAVES OF BERBERIS, &c.: Hortus. We know of no work on this subject in the English language.

CORRECTION: "Ideal" Label-holder. In the paragraph accompanying the figure of this label, p. 257, second line from the bottom for "my" read "any."

FIBROUS LOAM: Amateur. This consists of turfy-loam, dug about 5 inches, or less, in thickness; and to be fit for potting, it should have been an entire year in stack. The stacking ensures the partial decay of the roots of grasses and other plants contained in it. It should be pulled to pieces by hand—not chopped up with a spade.

GLASS HOUSE ON A SLOPE OF 1 FOOT IN 40 FEET, OR 5 FEET IN TOTAL LENGTH (200 FEET) OF RANGE: D. H. We should advise the range being built on the level by throwing down the soil from the upper half of the site of the range to the bottom; or by sinking the upper end of the range into the ground, so as to obtain a level or nearly level floor. With the range built in this manner you could have the boiler in a sunken stokehole, either at the middle or end of the range. If the slope be not altered, the boiler should be built in great part above ground, with a not greater rise in the flow pipe than 1 foot in the total length. The disadvantage of having a boiler fixed in a sunken stokehole at the bottom end of a range built on sharply ascending land, consists in the more distant sections of the piping getting much hotter than the lower—a serious matter—especially in hard weather.

GRAPES: A. C. If, as you say, the Grapes last year were black, there has, of course, been a sport, but we prefer to think that some mistake has arisen. Is there any graft upon the Vine? The bunch is not sufficiently good for us to say whether or not it is a known variety. The tunnel you speak of can have no effect upon the Vines whatever.

HYACINTH BULB: Agave. It contains myriads of the mite, at one time thought to be peculiar to the Eucharis, but which may be found upon almost all bulbs, that through any cause have become decayed. Burn all Hyacinths so attacked.

INSECTS: F. K. The common cockroach (*Blatta orientalis*), very destructive in an Orchid or any other plant-house.

LADY DOWNES' SEEDLING GRAPES: W. A. F. The want of colour and sweetness seems to point to a lack of heat during the earlier stages, and also at the finish, as Vines started in March should have ripened their fruit by the end of September. The bunch sent is well set with fine large berries, only they are not quite ripe, nor are they black. Lack of colour is a not uncommon fault with this variety. We think that your excessive use of artificial manure may have had something to do with the bad colour of the berries, by causing late growth, which would ripen badly, as would also the fruit; and if no fire-heat was employed during the latter part of August and the whole of September, the evil effects noticed might occur. Assuming that the five applications of manure amounted to 10 oz. per square yard, you have applied it at the rate of 24 cwt. per acre—three times more than was needed.

NAMES OF FRUITS.

* Applications to name fruits are so numerous at this season that it is impossible to do so in the exercise of our editorial duty. They entail an expenditure of time, labour, and money, and our readers can have little idea. We are most desirous to have our correspondents as far as we can, but we must request them to observe the rule that not more than six varieties at any one time. The specimens must be good ones, just at the ripening, and they should be properly numbered, and fully packed. We do not undertake to send answers then post, or to return fruits. Delay in any case is unavoidable.

E. F. T. Apple Eckinville; 1, Beurre d'Espérance; 2, Duchesse d'Angoulême; 3, Passe Colmar; 4, Haeon's Incomparable.—*C. Roskill.* 1, Hawden; 2, Cox's Orange; 3, Brabant Bellefleur; 4, Not known; 5, Golden Spire; 6, Pear, Conseil la Cour.—*H. Oakley.* 1, Margil; 2, Margil Ribston Pippin; 3, Golden Noble; 4, Not known; 5, W. Henderson; 6, Passe Colmar; 7, Flemish Beauty; 8, Williams' Bon Chrétien; 9, Gansel's Bergamot; 10, Emile d'Heyst.—*J. J.* We have not been able to identify the Apple sent us with certainty. It resembles Emile d'Heyst in some respects, and King of the Pines in others. It is of considerable merit.—*H. C.* 1, Blenheim Orange; 2, 10, Scarlet Nonpareil; 3, Braddick's Nonpareil; 4, Wadhurst Pippin; 5, Dutch Codlin.—*D. J. H.* Apple not recognised; 6, Southern; 1, decayed; 2, Souvenir du Comte de Lamy.—*W. Davey.* 1, 4, Eckinville; 2, not recognised; 3, probably Ringer.—*E. S.* 1, Peasgood's Nonsuch; 2, Eckinville.—*J. J.* 1, Margil; 3, Cat's Head; 4, worthless.—*X.* Cellini Pippin.—*J. F.* 1, Pitmaston Duchess; 2, small Duchesse d'Angoulême; 3, Alex. Lambré; 4, Maréchal de la Cour; 5, 6, Beurre.—*S. Brown.* 1, Yorkshire Beauty; 2, Duchess of Oldenburg; 3, Emperor Alexander; 4, Colonel Vaughan; 5, Mank's Codlin; 6, Gravenstein.—*D. Dixon.* We cannot name such a specimen.

NAMES OF PLANTS: Correspondents not answer this issue are requested to be so good as to send the following number.—Hollies. 1, Ilex aquifolium; 2, I. a. rotundifolia (probably); 3, Hendersoni; 4, I. a. myrtifolia; 5, I. a. serrata; 6, I. a. Belgica (probably).—*H. C.* 1, I. torium purpureum.—*E. Smith.* Liquidambar styraciflua.—*H. C. Prinsep.* Billbergia Portulacastrum.—*Armitage Brothers.* Erigeron speciosus, form.—*L. M. C. S.* Salvia azurea.—*H. C. Leicester.* We do not recognise the grass.

SAND, &c.: Amateur. Unless the loam is tenacious, leaf-soil mixed with it in the proportion of 1 to 1 will suffice to give the desired pot without the use of sand, but leaf mould is a scarce commodity in amateurs' gardens, and decayed, less suitable vegetable-matter has to be used instead, and sand becomes a necessity. If sand if it be washed of the loam often found with it answers well enough.

THE ROSARY AT LUTON HOO: A Subscriber. Unfortunately, we have no figure showing the position of the ground, but if our memory serves us aright, the rosary is situated in a natural hollow in the grounds, and is connected with the hardy fernery, and it has a walk running down the centre, and at its widest part, a circular path furnished with flower-beds. If this note catches the eye of Madame de Falbe's garden would, perhaps, kindly furnish the particular desire.

VINES: A. B. H. If the wood be well-ripened Vines will fruit more abundantly next year than the canes were raised the same year, they planted, i.e., 1894, they should have borne a dozen bunches each this year. If older Vines planted, the crop should have been larger. We would advise you to obtain a manual on the culture; the kind of knowledge required to grow good Grapes and other fruits, &c., not coming to any one naturally.

DIED.—WILLIAM A. STILES, the Editor of Garden and Forest, New York, U.S.A., on Wednesday October 6.

THE

Gardeners' Chronicle.

SATURDAY, OCTOBER 23, 1897.

THE HORTICULTURAL TRADE DURING THE PAST SIXTY YEARS.

THE article which appears in the *Gardeners' Chronicle*, p. 225, on "The Horticultural Trade During the Past Sixty Years," by Mr. Richard Dean, appears to me most excellent and interesting. Mr. Dean must have devoted much labour and research concerning the earlier years of Her Majesty's reign in producing this valuable information.

As I was in the nursery, as well as the seed trade sixty years ago, and had transactions with most of the nurserymen and wholesale seed firms of those days, I am able now, being in my eighty-third year, to testify to the correctness of Mr. Dean's account, which not many others in the trade now can do. There are very few of the firms mentioned in this article which I do not well remember, and not one appears to me to be incorrectly named or described. I may, however, be able to add a few remarks concerning some of them, which may afford additional interest to your many readers, especially the elder of them, who are still in the nursery and seed trade, or who have retired from it, as I myself did with my brother Alfred nine years ago.

Mr. J. G. Waite mentioned by Mr. Dean as of Hatton Garden in 1837, I knew, first as a market gardener at Camberwell, with a public-house conducted by some members of his family, while he attended to his outdoor business, which at that time included growing Lettuce and Radish seeds, which I used to buy of him fifty or sixty years ago. From Camberwell he removed to Hatton Garden, thence to Holborn (New Oxford Street), continually increasing his premises and business. He was an uneducated man, but clever, and very energetic, greatly annoying the older wholesale seed firms, as he did not join their ring or syndicate, but greatly undersold them, doing an enormous business. But his health gave way, and the business fell into the hands principally of his nephew, Mr. Burnell, who removed to Southwark Street, where a highly respectable trade was carried on under the title of Waite, Burnell & Co.

Flanagan & Son, Mansion House Street, as stated by Mr. Dean, carried on principally a retail trade, including the sale of Dahlia plants, when Criterion, Widnall's Perfection, and other new kinds, sold freely at 10s. 6d. each.

The firm of Noble & Co., originally William & John Noble, was one of the oldest of the wholesale houses; but the two brothers died almost suddenly, one of cholera; and Mr. R. Cooper and Mr. Bolton, who had long served them, became proprietors of the same firm,

under the title of Noble, Cooper & Bolton. But the oldest firm which I remember was Beck & Co., subsequently Beck, Henderson & Child, from whom I used to purchase seeds previous to contracting with certain farmers and gardeners to grow specially for my firm, trading in my father's name, as I was only sixteen years of age. In reply to our inquiry as to when we first dealt with them, Messrs. Beck, Henderson & Child replied, in a letter now before me, "On referring to our books, we find that we first had the pleasure of opening an account with your house on February 3, 1831, in the name of John Sutton; the first alteration was in 1837 to John Sutton & Son, and subsequently to John Sutton & Sons in 1846." Very early in the period Mr. George Batt, a former assistant in Beck & Co.'s business, started trading at 412, Strand, which firm subsequently became Batt & Rutley, and then Batt, Rutley & Silverlook.

Of the firms of Gibbs & Co., I may mention that the original was Thomas Gibbs & Co., of Halfmoon Street, Piccadilly, which firm was subsequently carried on by Mr. Thomas Gibbs' son, Mr. T. B. Brandreth Gibbs, who became Sir Brandreth Gibbs, Honorary Secretary and Director of the Smithfield Club. Besides the original Thomas Gibbs, father of Sir Brandreth Gibbs, there was a brother of his, Mr. George Gibbs, who carried on business at the same time at Down Street, Piccadilly, who, dying, left the business to his son, Thomas Gibbs, Jun., who died only a few years ago.

Of nurserymen, Mr. T. Rivers, Jun., of Sawbridgeworth, was by no means a young man in 1837, though his father was still living. He was an enthusiastic and scientific botanist, as well as a nurseryman, and he excelled, not only in fruit trees, but also in Roses, taking periodical journeys to France for collecting sorts of Roses and Pears which were new to English cultivators. I knew him intimately, having slept several times at his house, while on business visits. At that time he had a considerable retail seed trade, though he devoted his attention principally to the nursery; while I had a considerable nursery trade, though interested chiefly in the seed trade. We both agreed that it was impossible to really excel as we wished while engaged in both branches, so he determined to give up the seed trade while I gave up the nursery trade. The establishment, in 1841, by Sir Joseph Paxton, Dr. Lindley, and others, of the *Gardeners' Chronicle*, did great service to the trade and to horticulture. Prior to this there had been Glenny's *Gardeners' Gazette*, the first weekly horticultural paper, which was very good in its way, but was deficient in many important particulars. Harrison's *Floricultural Cabinet* existed as a monthly illustrated periodical. The *Gardeners' Chronicle*, however, met fully the requirements of nurserymen and seedsmen, and was an invaluable medium of communication between the trade and their customers, many rising firms increasing their trade rapidly by advertising freely in this paper, which soon became extensively circulated.

Another nursery firm mentioned by Mr. Dean is worthy of special notice, namely, Waterer of Knap Hill. This firm has always been the largest for American plants and Conifers of any in the kingdom, and is now the largest in the world. For many years at Bagshot Mr. John Waterer had a very fine stock of choice American plants, with an extensive retail trade; while the Knap Hill firm confined themselves principally to the wholesale trade. The Knap Hill firm in 1837 was carried

on by Mr. Michael Waterer, who was succeeded by Mr. Hosea Waterer, who was followed by Mr. Anthony Waterer (lately deceased), and now with continued energy and ability by his son, the present Anthony Waterer. I remember many years ago meeting, in the blooming season at the Knap Hill dinner-table, a large number of nurserymen, including Chandler, of Vauxhall; Lee, of Hammersmith; Kernan, of Russell Street, Covent Garden; and others. During several weeks of every summer this was a rendezvous where nurserymen were sure of meeting each other.

The Brothers Brown, of Slough, to whom Mr. Dean refers, were three in 1837, Charles, Thomas, and Edward. Charles was the eldest and most experienced nurseryman, but he died early. The remaining brothers carried on the business at Slough energetically, with the addition of a shop in Piccadilly for the sale of plants and flowers, which they sent up daily for a year or two. I remember at one of the Dahlia shows at Salt Hill, Charles Brown and Mr. George Glenny, editor of the *Gardeners' Gazette*, had the honour of conducting Queen Adelaide through the show, and the Browns having exhibited a fine stand of a new seedling Dahlia, it was by permission named "Queen Adelaide," a delicate white flower tipped with rose. A few years later Edward Brown retired from business, and Thomas went abroad, being succeeded by Mr. Cutter, from America, who very soon gave it up to Mr. Charles Turner, who excelled all others in florists' flowers, from which time it has been entitled the "Royal Nursery," and we all know what an extensive business is now carried on by his sons.

Messrs. Brown were famous for the finest bed of choice Tulips in the kingdom, which Charles Turner continued to cultivate for some years, but before his death he distributed these valuable bulbs among several of his friends. A useful lesson for us all was taught by Mr. Turner. Though he had an experienced foreman for each department, he "saw to everything himself." When a great Dahlia show was drawing nigh, he would watch and shade the blooms selected, and finally cut them and pack them himself, and travel all night if the show was far distant that he might himself make the final selection from the boxes for the stand, in which he would himself set them up. It was the same with the Roses, Carnations, Pelargoniums, and other florists' flowers. Consequently (as he said), he always took first prizes, and rare indeed was it to see him second at any show. When speaking of the success we had each attained in business, I remarked that I did not think I could ever have excelled as a nurseryman and florist as he had done, he replied, "Oh, yes, you would, if you had given the same personal attention to it that you have given to seeds."

One other among the nurserymen of 1837, named by Mr. Dean, Mr. Skirving, of Liverpool, is worthy of more special notice. He raised many thousands of the *Araucaria imbricata* from imported seed before anyone else in England, supplying the trade extensively; and as a seedsman he was distinguished by raising and introducing the "Skirving Swede," which he exhibited at the Smithfield Club shows when they were still held at the Baker Street Bazaar. This Swede produced 40 to 50 per cent. more bulk and weight per acre than the old Purple-top and Green-top Swedes then in cultivation, though rather coarse compared with the Caamption and other large globular Swedes since introduced. Mr. William Noble (of Fleet Street) remarked to me that Skirving had done more than any man for flock-masters by intr

ducing that Swede, and that he (Mr. Noble) had made hundreds of pounds by selling the seed.

Another firm should be mentioned — the Ronalds of Brentford, who were thoroughly established as wholesale seed merchants as well as nurserymen as early as 1837.

In addition to the Lawson firm alluded to by Mr. R. Dean at p. 225, mention should also be made of the Drummonds. Concerning this gentleman, the following extract from a letter from Mr. Peter Drummond, dated June 29, 1854, affords information:—

"There are four brothers of us connected with the seed, nursery, and implement business. Since 1843 we have had a branch in Dublin, managed by one of my brothers, who, with his family, resides there, with a good staff under him. Here (at Stirling) one of my brothers looks after the nursery department, with a staff under him. The seed department here is now superintended by one of my brothers, although I had hard work at it a good many years. (Signed) PETER DRUMMOND, Stirling, N.B."

I think, too, that Mr. Dean would include among the distinguished early Rose growers Messrs. Wood & Son, of the Maresfield Nurseries, near Uckfield, Sussex. *Martin Hope Sutton.*

NEW OR NOTEWORTHY PLANTS.

ASPIDIUM PURDLEI, *Jenm., n. sp.*

STIPITES stout, erect, 1 to 1½ foot long, glossy, brown, or castaneous, as are also the rachises and ribs; fronds erect, 1½ to 2½ feet long or more, ¾ to 1½ foot wide, pinnate, chartaceous, pellucid, glabrous, dark green, composed of a large terminal trilobed, or ovate-oblong and acuminate segment, a span to a foot long, 4 to 8 inches wide, more or less deeply lobed at the base, above sinuated or lobed, the apex plain, and two or more pairs of sub-distant, oblong, lanceolate-acuminate, up-curved lateral pinnæ, the owest of which are petiolate to 1 or 1½ inch, ½ to 1 foot long, 3 to 6 inches wide, the margins sinuated or lobed, the base deeply lobed on each side, the lobes being acuminate, and sometimes quite free; upper pairs sinuated or lobate, sessile or shortly stipitate, the base often deeply lobed, and somewhat rounded; primary veins costate, ½ to ¾ inch apart, very oblique, connected by a very copious fine areolation, containing more or less free included veinlets; sori very copious, moderately small, irregularly serial on each side of the main veins, and more or less scattered between; involucre reniform, curling with age, persistent; receptacles copiously minutely scaly.

Trinidad. Collected by Purdie at Maraval. In size, strength of the vascular parts, and conformation, this resembles *Aspidium macrophyllum*, Sw., from which it is distinguished by its copious and scattered (not bi-serial) sori. It is a larger, stronger, and more robust species than any of the other local species with scattered sori. *G. S. Jenman, Demerara, September 25.*

APERA ARUNDINACEA, *Hooker.* (Fig. 84, p. 283.)

This elegant New Zealand grass was raised from seed sown by Messrs. Veitch in their nursery at Combe Wood, near Kingston, in January, 1896. It was shown by them in flower at a recent meeting of the Royal Horticultural Society. Sir Joseph Hooker describes it in his *Handbook of the New Zealand Flora*, p. 326. Up to the present time, it has been grown in a cool house, but it may prove hardy in some places. It is a native of the northern island of New Zealand, and of the eastern shores of Australia.

ORCHID NOTES AND GLEANINGS.

TWO FINE CATTLEYAS.

Two grand examples of large-flowered Cattleyas are sent by Mr. Wm. Bolton, Wilderspool, Warrington, the one serving to show the variability of *Cattleya Warscewiczii*, and the other representing one of the highest forms of natural hybrid between that species

and *C. Dowiana aurea*. This was named *C. Massaiana Boltoniana*, and it received a First-class Certificate at the Manchester and North of England Orchid Society on October 7. The spike had four grand flowers, which have preserved their beauty and fragrance until now. It may be said that the name "*Massaiana*" is only a garden term for the form of *C. Hardyana* with white-mottled and veined sepals and petals. In Mr. Bolton's variety, the base of each of the sepals is silvery-white, the remaining portion bright rose with some blotches and veining of white. The lip in its gold veining, and broad crimson-purple front, is like the best *C. Dowiana aurea*, and the flower is very fragrant. A pretty feature in it is the striated purple margin of the side lobes of the lip.

The other flower is of a charming form of *C. Warscewiczii* of most perfect shape. The sepals and petals are white, suffused with a very slight tinge of lavender colour, which is not perceptible at a little distance. The lip is bright light purple, shading to lilac at the margin, and bearing the two patches of yellow colour, one on each side of the lip, as usually seen in the species, but in this one much lighter than usual. *J. O.B.*

CARDIFF PUBLIC GARDENS.

THERE has been a fortunate awakening in this country to the importance of securing sites in towns for the formation of public parks or open spaces. It is true that a lively interest has only been aroused when too late, in the case of many towns, to acquire sites close to the densely-populated areas that require them most. Land that might have been obtained years ago at comparatively small outlay has now become so valuable that to obtain it for the purposes of a public park or recreation-ground is out of the question. The same circumstances and results have happened in America. A circular just to hand gives particulars of a society founded in May last at Louisville, to be known as the "Park and Outdoor Art Association," and it has apparently the same objects as Earl Meath's Metropolitan Public Parks Association in London, which has done so much to preserve to Londoners their right of commons, and to purchase for them various sites for open spaces wherever it has been possible. In a paper delivered before the New York Historical Society by Mr. Gherardi Davis, the condition of New York is described in much the same terms as we should describe London; indeed, in respect to its open spaces, that city is unfavourably compared both with Paris and London. In some of the newer and better districts there are plenty of parks; in the older and more populated localities comparatively few, and that is the case in London. We must leave the general subject, however, to consider more closely what has been, and what is now being done in Cardiff, a town that has grown during most people's remembrance from comparative non-importance to one of the principal ports of the country. In the last fifteen years whole suburbs have been added; and even in 1891 the population was only 128,915, while to-day it is estimated at over 170,000. Following the enterprising and far-seeing policy of the late Lord Bute in building the docks, Cardiff developed so rapidly, that naturally little time was given to such a subject as this, when trade and commerce kept everyone busy. Not until about ten years ago, was it decided that Cardiff was to have a public park, and seven years since the council appointed its first "superintendent of parks and open spaces" electing to this office Mr. W. W. Pettigrew, son of the present gardener at Cardiff Castle.

ROATH PARK

is situate about 1½ mile from the town's centre, and consists of 109 acres. It was opened to the public three years ago. The site was given by the present Lord Bute upon certain conditions, including the making of public roads round and through the park. The land is inconveniently narrow, and for some years it will be impossible to confine the view to the park. Public roads intersect it at several points, and the land is thus divided into distinct sections, which have accordingly been laid out as such. The pleasure-grounds are 11 acres, the

botanic garden 15 acres, the lake section 41 acres, the wild-garden 8 acres, and the recreation-ground 23 acres. There are 2 acres known as the "oval" yet to be laid out.

The work connected with the formation of this park includes upwards of 3½ miles of 40 feet wide roads, and ½ mile of 30 feet roadway. The sections of the park are surrounded by 4½ miles of undimable iron-fencing. Coming to the gardener's work in the park, it should cause the town great satisfaction. We have already said that the site is a narrow one, and the park therefore is of great length. Any amount of landscape genius would fail to alter that fact, but there has been no opportunity neglected to minimise its disadvantages. The first section of 23 acres, viz. the recreation-ground, may be dismissed in a very few words, for important though it is as a play-ground, there is no horticulture in it. It is covered with grass. There are surprisingly few restrictions in regard to it, and it remains open day and night.

The lake section includes but little margin beyond the area of the lake itself. This is a magnificent sheet of water, and has been obtained by damming a stream that runs through the park. It is not surprising that such a beautiful and large area of water has proved a most popular resort for boating and bathing. But now the lake is made, and it is filled with water, all difficulties to the enjoyment of boating have not been overcome. The two water weeds, *Myriophyllum verticillatum*, L., and *Potamogeton pectinatus*, L., have given Mr. Pettigrew rather more opportunity than desirable for the practice of his destroying qualities. Some of the readers of the *Gardeners' Chronicle* may know of a ready means to combat the pests, and if this be so, such news will be very welcome to many superintendents of public parks. Only in the deepest water is the lake free from their growth; in other places they spring from the bottom, and after passing through the water float on the surface. To rake them from the water by means of boats entails very much expense and labour; and if allowed to become at all thick, they render boating dangerous, because the oars are liable to become fast in their coils. This too, although the water is bedecked with several pairs of swans, and numerous ducks, and other water-fowl.

The section known as the "Wild Garden" is kept in a freer style than the pleasure-grounds. The old shrubberies have been left, and most other of the vegetation. The grass is cut once or twice a year, but not before a host of planted bulbs have flowered, nor until the natural wild plants have blossomed. There are rustic bridges, a dripping water-course, pretty glimpses through the trees, and ingeniously disposed seats. It is altogether a place for quiet and natural enjoyment.

There are 11 acres reserved strictly as a pleasure ground; where the grass is kept closely mown and smooth, the verges are faultless, and there are trim flower-beds. The perfect verges themselves are sufficient evidence that you are not allowed to run over that grass; no, not even to examine the flower-beds. It is a pleasure-ground, the verdure is a law, and it is kept as one attached to a private residence would be. Of course, this may cause a little irritation to some of the visitors; one could hardly expect all of them to look at the question from the standpoint a gardener does, for to him an ill-used lawn is something past toleration. So the visitor must be content with the unrestricted use of the recreation-ground, the tolerable freedom he enjoys in the wild garden, and in the botanic section of which we shall speak presently. There is much else, however, to notice in the pleasure-ground beside the soft lawns and trim flower-beds: the natural watercourse through the ground has been widened and made pretty, the islands in the miniature lake presents a charming appearance, and some of the species of ornamental trees planted are interesting and uncommon; while those very essential ornaments of any pleasure-ground, the flowering-shrubs, are represented by select species.

The climate of South Wales being fairly mild, some of the less hardy of flowering-shrubs have been planted, species that, like *Paulownia imperialis*, are

able to be cut back severely in any but favourable calities. The Paulownia has commenced well, and making very robust growth; but will it bloom? ear to it is the one hardy species of *Clerodendron trichotomum*, a Japanese bush that grows about as gh as an ordinary man, very handsome, and figured the *Botanical Magazine*, tab. 6561. But none of the ees or shrubs have had time to develop much at

botanic garden, and whether or not in the other divisions there is evidence that the designer was once at Kew, there is sufficient here to suggest, at any rate, the work of a "Kewite." In these 15 acres there are large oblong beds, just as at Kew, where plants are grouped together in their natural orders, for the convenience of students who may visit the park. It is an excellent practice, and indicates

attempt the work in the largest of the parks, the extra facilities for the study of natural specimens will be appreciated. Some of the natural orders are even now fairly well represented in the beds at Cardiff, but others are less easy of acquirement, from the fact that whilst many of the orders comprise abundance of hardy plants, others consist of exotic and tender plants chiefly, and so the beds are not easily furnished. The Sedums and Saxifragas were especially comprehensive, and the pieces of stone studded in the surface of the soil, appeared to suit them well. I took a number of notes of various plants here, and of some uncommon flowering species that had been planted to furnish vacant spaces in these beds for the summer, but I withhold them, for the reason that it is desirable to refer briefly to the other open spaces in Cardiff. At the highest point, in a fully-exposed position in this section, where the sun will reach the plants without obstruction, a rockery has been made, and the process of clothing this with a representative collection of plants is going on. In front of it is a bog, where plants that require such a position will find a suitable place. Already, several rare species have been put there. Adjoining this is a peat-border, where those hard-wooded species known as American plants have been grouped. Visitors are allowed to wander over the grass in the Botanic Garden as they desire.

VICTORIA PARK

has an area of 25 acres, and is in a suburb of the town called Canton. It was first opened to the public a week previous to the Jubilee festivities, and accordingly the name of Ely Park, by which the site was hitherto known, was changed to "Victoria" Park. It is provided with a small lake near the centre, and in this is a fountain of the "Convolvulus" type. It throws up a beautiful volume of water in the shape of a Convolvulus. There is a band-stand, and the design of flower beds, paths, shrubberies, &c., is pleasing. Incidentally, some Rose beds, the Rose-plants in which were unusually vigorous, were noted.

SMALLER AREAS.

Sites for open spaces have been preserved in various parts of the town. Canton Recreation Ground comprises eleven acres, and a piece of land of equal size adjoining, is let as allotments, but belongs to the town. Grange-town Open Space covers 3½ acres, and was opened to the public two years ago. Like some of the other sites, it had to be made up to its present level by adding 3 feet deep of town's refuse. Despencer and Clare Gardens at Riverside, represent a little more than 1 acre.

In the Splotlands, an area of 1½ acres is known as Moorland Road Gardens, and is in one of the newest districts in the town, close to the Channel. Loudon Square, on the contrary, is in one of the oldest and most densely populated districts. Its area is about 1½ acres. In Canton the Plasturton Gardens are ½ acre, and in Roath the Howard Gardens are 1½ acre, and the Roath Church Gardens ½ acre. There is still another garden of about ½ acre known as Adamstown Square.

Cardiff may be considered fortunate in that something like forty years ago the late Marchioness of Bute lent for the town's use what is now known as the Sophia Gardens. It is a park of considerable size, and is not more than five minutes' walk from the centre of the town. It has never been given to the borough, and the cost of maintaining the grounds in condition is not shared by the ratepayers. In the Sophia Gardens are held the annual horticultural shows, and for this and similar purposes it is very suitable. The public have also the privilege of use of another private park 10 acres in extent belonging to Mr. Pyke Thompson. Neither this nor the Sophia Gardens, however, must be counted among the open spaces of the borough. Very recently Cardiff has acquired two sites that, though for some time to come they may not be laid out as parks, must be mentioned here. The first is Cathay's Park, 60 acres in extent, recently owned, by Lord Bute, and adjoining the Castle Gardens within a couple of minutes' walk of the town. It is intended to build a new Town Hall upon this site,

FIG. 84—APURA ARUNDINACEA: A GRASS FROM NEW ZEALAND. (SEE P. 282.)

present, and it would be uninteresting to enumerate them. The plantations in some cases contain Michaelmas Daises as stop-gaps until more growth has been made, and in the present month the landscape is the better for them; they are yielding masses of bloom. Near to the entrance to the pleasure-ground section has just been completed a residence for the superintendent.

Now we come to the section which is laid out as a

that Mr. Pettigrew is doing the most he can to afford means of education as well as recreation. By-the-way, there appears to be a disposition on the part of the London County Council to add such a feature in a modified form to the metropolitan parks. Anent this, it will be worth while to remember that a botanic garden is not requisite in every parish, and Kew is not a great distance from any point in London. At the same time, if the Council only

but otherwise the ground must remain an open space, in accordance with a stipulation of Lord Bute's. The other piece of ground is at present known as Llandaff Fields, in the direction of the town approaching the village and city of Llandaff, where there is an ancient cathedral. This site was purchased for something like £69,000.

To sum up then the parks and open spaces at present belonging to the town, amount to something over 250 acres, and nearly the whole of this has been acquired very recently. The borough is evidently awake to the importance of the subject, but it will no doubt do more than has been commenced, and before long. Cardiff does not possess a winter garden. It ought to do so, either in the Roath Park or somewhere else; and if it should be built in Cathay's Park, it could not possibly be given a more convenient position. *R. H. Pearson.*

AMERICAN NOTES.

THE POTATO SCAB.

(From our own Correspondent.)

MR. H. H. WILLIS' recent note in the *Gardeners' Chronicle* on this subject may or may not have furnished novel information to European readers, but when the Potato-scab is spoken of here, one as naturally thinks of corrosive sublimate as he does of thunder when he sees lightning. The use of corrosive sublimate, however, is already threatened. Thanks to our great State experiment stations, the march is ever onward, and in the hands of Dr. Halsted, of the New Jersey station, ordinary flowers-of-sulphur have given the most satisfactory results. This is dusted in the rows at the rate of 200 lb. per acre. Dr. Arthur, of Indiana, has lately investigated formaline as a preventive, and his conclusions, as given in a recent bulletin, are favourable. However, the value of this can hardly be said to be fully demonstrated as yet.

AMERICAN INSTITUTE SHOW.

The great annual "fair," or exhibition, held under the auspices of this body, is now in progress in New York city. The first week's horticultural display was made up chiefly of Dahlias, which were of remarkably fine quality. One noticeable feature of the show was the hitherto unknown men who came into the competition, and altogether some 50,000 blooms were staged. The fact that so widespread an interest really exists in the Dahlia was not realised by New York, and the recent show was an education in a way not expected by the promoters. The growing interest in the Dahlia is very real, and the American Dahlia Society, with headquarters in Philadelphia, Pa., is doing a missionary's work. The new type of large-flowered Cactus Dahlia is very much in favour, and far excels the show or fancy in popular estimation. Mrs. Agnew and C. W. Bruton, respectively fiery-crimson and sulphur-yellow, are specially fine varieties. Among new plants there is nothing not already made familiar by your own shows. One exhibitor, Mr. Duckham, sends a marvellous display of plants never before exhibited in New York, embracing Palms and Rex Begonias, all from the St. Albans nurseries of F. Sander & Co.

ENGLISH TOMATOS.

There is quite a "boom" on these for forcing purposes, as I have already mentioned; but now along comes another very capable gardener, and argues for them for the general crop. Surely there is a good chance for some wide-awake seedsman.

DEATH OF W. A. STILES.

On October 6, the horticultural circle suffered a sad loss by the death of the popular managing editor of *Garden and Forest*. In recent years Mr. Stiles had been a visitor to Europe, and there as at home, endeared himself to all who had to do with him. Mr. Stiles had been laid up for many weeks, after years of struggle against a fatal disease, cancer; but none the less the news of the end was a sad shock to his many friends. Born in 1837, he graduated from Yale in 1859, and became a teacher in his father's school. From that

time on, he had an eventful career, and always by his forceful personality forged his way to the front. He was for a time engineer for the Union Pacific railway, and subsequently became identified with politics. He drifted into journalism, and became agricultural editor of the *Philadelphia Weekly Press*, and afterwards was on the staff of the *New York Tribune*. During the time that he was in California, Mr. Stiles began what afterwards became the chief study of his life, that of plants and flowers, and during his long convalescence in Sussex county, N.J., he spent much time in roaming about his father's large farm, collecting plants and flowers, and gaining a practical knowledge of them and of their habits. This love of plant-life grew to a passion, and he became an expert in botany. When Professor Sargent started *Garden and Forest* he selected Mr. Stiles for managing editor, and, together, they made long trips on horseback through the forests of North Carolina in order to further their knowledge of arboriculture. Everything which the earth produces in the way of plants, trees, flowers and shrubs possessed a vivid interest for Mr. Stiles, and although not a practical horticulturist, he was one of the first critics of landscape gardening in America. For many years before Mayor Strong appointed him a Park Commissioner, Mr. Stiles took a deep and practical interest in the park system of the city, and he was always ready to defend with his pen the recreation grounds of the people from the encroachments of those who favoured the use of them for all sorts of schemes for which they were not intended. From the day he entered the Park Board, he was a vigorous champion of expert judgment on all matters pertaining to the making of parks; there was not one of his colleagues who did not respect his ability, and acknowledge that he was the best qualified man in the Board for the place of Park Commissioner. Alone he fought the adoption of the plans for the Botanical Garden in Bronx Park, which a committee of experts had condemned, and in this he had the support of nearly every newspaper in New York, as well as the Federation of Fine Arts. A clear and forcible thinker and speaker, Mr. Stiles was a valuable ally, and the present writer mourns the loss of a friend. [Mr. Stiles' death was briefly announced in our last issue. Ed.]

THE NEW YORK BOTANICAL GARDENS.

At last all the skirmishing is over, and we shall get a botanical garden in New York city. There has been a tussle between the Park Board (who by the act of Legislature had to give the ground and approve plan) and the directors of the garden. Until the plans were passed by the Park Board no progress could be made. Now all is over, the necessary 500,000 dols. have been voted, and the work should be pushed along. *L. Barron.*

THE FEEDING OF PLANTS.

DURING a recent visit to Versailles, I was much struck with some experiments in the feeding of plants in pots which M. Georges Truffaut has been conducting by means of artificial manures. The novelty of these experiments lies in the method of the application. Briefly, M. Truffaut has reasoned thus: Theoretically, every plant requires its special food; but practically to supply this would be impossible—so we must group together plants having nearly the same wants and equal rapidity of development.

For some six years, M. Truffaut has been working with a view to ascertain accurately the requirements of each plant. 200 analyses have been made, and of these some thirty groups have been formed. There are groups of quick-growing plants which need much food in a short time; and slow-growing plants requiring little food, but extended over a long period.

The right amount of properly proportioned vegetable food brought to within 99 per cent. purity, required for, say, six months, is weighed and then divided into two, four, or six pills (capsules), according to the rapidity of growth and the quantity required. All the salts used represent the general requirements of the group, and are perfectly dry, pure and immediately soluble.

The capsules (or pills, as M. Truffaut prefers to call them) have a metallic cover which prevents too rapid diffusion and solution. The diffusion takes place through the foldings of the metal, and the thicker the coating the slower the diffusion. Greater compression also retards the diffusion.

As the salts dissolve and disappear they are replaced by a core which expands until it completely fills the pill. The salts have no effect upon the metal cover, so that the pill remains firm and hard, and is always clean and unobjectionable in every way. Thus, by the three means, of metal coating, compression, and an expanding core, M. Truffaut has been able to regulate to a few days the solubility of a pill of immediately soluble salts, in experiments of three weeks to six months' duration.

By this process, anyone would be able, without danger of mistake, to give the correct amount and exact requirements to each group of plants, or indeed, practically speaking, to every plant. The waste of nitrogen, hitherto an expensive drawback to the use of artificial fertilisers, is obviated.

The plants, thus treated, which I saw at Versailles, are wonderful recommendations of the value of the method. The chief plants were:—

<i>Pteris tremula</i>	<i>Pandanus utilis</i>
" <i>cristata</i>	<i>Dracena Bruanti</i>
" <i>serrulata</i>	" <i>amabilis</i>
<i>Geranium</i>	<i>Asparagus plumosus</i>
<i>Canna</i>	" <i>Sprengeri</i>
<i>Bouvardia</i>	<i>Corypha australis</i>
<i>Fuchsia</i>	<i>Kentia Belmoreana</i>
<i>Cuphea</i>	<i>Curculigo</i>
<i>Chrysanthemum</i>	<i>Lantana</i>
<i>Adiantum</i>	<i>Areca sapida</i>
<i>Phoenix</i>	<i>Coccos Weddelliana</i>
<i>Colusa</i> , treated by analogy	<i>Acalypha Macfleckana</i>
only (a failure)	<i>Davallia macrophylla</i>
<i>Scorothia</i>	<i>Begonia Rex</i>

The plants, instead of being potted-on, have been fed in this manner, and they are large, splendidly coloured plants, in pots which are one-half the usual size.

M. Truffaut has furnished me with details of the analysis, &c., of *Dracena Bruanti*, as an example of his method; the weights are in grammes (15 grains = 1 gramme approximately):—

DRACENA RUBRA BRUANTII.			
Leaves	57.63	per cent. of weight
Stems	22.19	" "
Roots	20.17	" "

One Plant.	Fresh State.	Dry.	Dry Matter.
	Grammes.	Grammes.	
Leaves ...	300	57	23.5 per cent.
Stems ...	77	17	22.07 "
Roots ...	70	14	20.0 "

Fresh state, 347 gr.; dry, 88 gr.; 25.36 mean per cent.

One hundred Parts of Dry Matter contain—

Constituents.	Ashes.	Nitrogen.
Leaves ...	5.94	1.31
Stems ...	5.76	.73
Roots ...	6.15	1.39

One hundred Parts of Ashes contain—

Silica ...	8.64	Chalk ...	18.02
Chloride ...	5.93	Magnesia ...	3.97
Sulphuric acid ...	7.98	Potash ...	22.10
Phosphoric acid ...	0.48	Soda ...	1.70
Iron oxide and alumina 17.14		And some carbonates	

A careful calculation gives the following mixture required for the plant:—

Ammonia phosphate...	Percent.	Nitrate of soda ...	Percent.
Ir.-n sulphate ...	8.1	Chloride of ammonia...	4.3
Magnesia sulphate ...	12.7	Nitrate of potash ...	45.5

Each plant receives five pills of 2 grammes each for eight months' growth.

The illustration shown (fig. 85) is a photograph of one untreated plant, and one treated with its proper food in pill form; the difference is apparent.

Pending the completion of his experiments, M. Truffaut has patented his process in France, England, and other countries. I cannot vouch for the accuracy of the figures given above, as I regard this subject entirely from the point of view of a practical gardener; but M. Truffaut is well known as a trained chemist, and he has been working in conjunction with one of the most prominent young scientists in France, *Georges Louis Paul, Chénant*.

SHORT-EARED OWL

(Otus [Strix] brachyotus).

Short-eared owl is different in its habits from those found in Great Britain, which live in thick and plantations, or in barns, churches, and seldom leave their retreats during the day. Those of the short-eared owl are heath and moor-shes, furzy downs, meadows, Turnip-fields, and ces, principally in the north of England and, though it is found occasionally in many counties. It flies in the daytime, and may hunting for mice, voles, and other vermin at of the day. Prentis in his *Birds of Rain-ent*, says that the short-eared owl is not on, and comes in the autumn. It visits the where it is safe, nearly every year. When part-otting, sportsmen have met with the owls in

a normal winter migrant to these islands, appearing simultaneously with the woodcock (whence it is popularly known as the 'woodcock owl'), and usually departing in spring. Nests in ordinary seasons are of comparatively rare occurrence in Great Britain, but in consequence of the vast multiplication of their favourite food, the vole, these owls have not only arrived in unusual numbers, but have remained and bred freely all over the district affected, laying from eight to thirteen eggs (though Newton in his edition of *Yarrell's British Birds* mentions seven as an unusual number), and rearing more than one brood. The shepherd on Crooked-Stone, near Crauford, has counted fourteen nests on his ground. The small wood behind the farmstead of Howpasley presented a remarkable appearance, the ground being densely covered with the pellets (or 'castings') of owls composed of the fur and bones of the voles."

pale buff, and the toes black. The beak is also black, and the ears, as well as the tufts of feathers on the head, are brown. The eggs are creamy-white in colour, and about $1\frac{3}{4}$ inch long by $1\frac{1}{4}$ inch in breadth. They are deposited on the ground in a nest scooped out of the earth, and lined with a little dry grass or moss. The nest is made generally in tufts of Heather or Furze, or in grassy spots. Sometimes it is found in marshy and fenny spots in reeds and rushes. Nests have been occasionally found in the Kentish marshes on little hillocks covered with rushes. From four to seven eggs are generally laid, but, as was shown by evidence before the committee cited above, as many as thirteen eggs have been found in a nest. Seebohm, in his *Far Countries of North America*, quotes Richardson to the effect that this species of owl lays as many as ten to twelve eggs.

The short-eared owl is much appreciated in Germany, where it is called the "moor," "fen," and "meadow" owl. It occasionally breeds in Germany, as in England, but generally arrives in September, and remains till March. In France it breeds in the Pyrenees, Charente Inférieure, Hérault, Tarn, Aude, and other Southern Departments, but not very extensively. Board of Agriculture, 4, Whitehall Place, S.W., August, 1897.

METHODS OF PROPAGATION.

(Continued from p. 227.)

THE Oleasters (Eleagnus) are easily increased by taking cuttings of the young shoots, inserting them in sandy loam under a bell-glass, keeping them moist, close and warm. Some of the Japanese species are very handsome, namely, *E. reflexa aurea variegata*, the foliage of which is persistent in ordinary winters, even without the protection of wall or fence.

Escallonia in all its charming varieties, is readily increased by cuttings of the matured young shoots, but the best result is obtained by the use of a hot-bed with a gentle and lasting bottom heat, the frame lights or hand-lights and bell-glasses being kept close till rooting has taken place. The potted-off plants should be placed in a cold frame, and shaded from strong sunshine till established, when shade must be dispensed with. Most of the species of *Escallonia* are Chilean, and only withstand our winters in the south and west; while inland, and in the north they require planting against warm walls or fences.

Forsythias. These plants are shrubs that do well in the open or on low walls, and are perfectly hardy. Cuttings made of the matured shoots strike readily in the open ground, but rooting requires a long period of time. When well rooted, plant them out in spring or early autumn in nursery lines, $1\frac{1}{2}$ foot apart.

Iciss are propagated from cuttings of the young wood, put under bell-glasses or hand-lights, in the case of the smaller and more delicate varieties. The cuttings strike more readily on gentle bottom heat. The Tree Ivies, and some others enumerated under that head, should be grafted on stocks of English Ivy. *Hedera helix* on which straight stout stems are made, in which form the plants are very useful decorative material, especially variegated forms, very nice for winter bedding in the open air.

Jasmines may be raised from cuttings of ripe one-year old shoots, which should be cut into lengths of 9 inches to 1 foot, severing them at a node, and inserting them in a prepared bed of soil, covered with a close-fitting hand-light, or with a bell-glass, the early autumn being the best time to take cuttings. These soon callus, and the following spring they form roots.

Honeysuckles, so useful as climbing plants, and equally desirable for the fragrance of their flowers, are easily multiplied from cuttings made of ripened shoots taken off in September, and inserted in the open ground, like Currant-cuttings; or they may be put into propagating-pans in a cold pit, where, by keeping them close and shaded about mid-day, they very soon make roots. As soon as this is effected, pot them singly and plunge in spent tan, sand, or coal-ashes.

Shrubs which may be struck from Cuttings.—Laurels in variety are often required in large quan-

FIG. 85.—DRACÆNA RUBRA BRUANTI: UNMANURED AND MANURED. (SEE P. 284.)

Turnip-fields. On one occasion a pair nested in hatching their young on an island which had been lying idle throughout the and spring. But this owl, being migratory, as a rule, breed in Great Britain; it leaves try at the beginning of the spring for many untries, so that, to use Seebohm's words, our islands its range is almost cosmopolitan. d in such different latitudes as the Sandwich Greenland. Sometimes, however, as ornitho-late, its nest is found in this country, especially where there has been an extraordinary of its favourite food—mice, voles, or rats. In ershire, for example, when there was a great 'mice in the forest of Dean, short-eared owls acted there in large numbers, and materially n destroying the intruders.

Departmental Committee appointed in 1892 board of Agriculture to inquire into a plague roles in the south of Scotland, say in their 'This bird (i.e., the short-eared owl), which uted over almost every part of the globe, is

The committee were of opinion that it would be difficult to condemn too severely the foolish and cruel action of those who allow or encourage the destruction of this useful and beautiful bird, and it was with much satisfaction that they were able to record that many landowners and game preservers had become convinced in late years that owls of all sorts are not only harmless to game, but most beneficial to agricul-turists, and had issued orders for their preservation. Seebohm also writes strongly on this point: he says, "Too often, however, the poor harmless owl is shot down by thoughtless farmers or ignorant gamekeepers, who foolishly imagine they are ridding the domains of a pest, although in reality they are taking the life of one of their most valuable friends."

The short-eared owl is from 14 to 15 inches in height. The female is rather larger than the male. The head, back, and wings are lightish-brown, with darker brown patches upon them. The wing feathers have an edging of light buff or fawn colour, and the under surface of the body is of this colour, with blackish markings upon the breast. The legs are

ties, and all are more or less easy of increase by cuttings of the young wood taken with a heel. The common practice in nurseries is to bed the cuttings in close rows on a north or east border, but small quantities may be raised by inserting similar cuttings round the rim of an 8-inch pot, putting the cuttings deep down that the base is about an inch off the crocks, and after watering the pots copiously plunge them in a cold frame in any light kind of material. Care should be taken that the soil never gets dry, or the young roots will perish.

Laurustinus, in all its varieties, may be struck in the same manner as Laurels, but it is advisable to lighten the soil by adding some sifted peat and sharp sand; but here, covering the pots with bell-glasses hastens rooting, although even then quite twelve months are needed in the process.

Deciduous species of *Viburnum*, viz., the Snowball, *V. opulus*, root readily as a cutting in the open border; and the sub-evergreen Chinese and Japanese species, *V. plicatum* and its woolly-leaved variety *lantanum*, as well as the American species, are raised from cuttings of the mature wood, where layering is not convenient.

Acuba japonica roots freely if the cuttings be taken in the autumn, as soon as growth is finished, the coarse pithy shoots being avoided, as these scarcely ever can be got to strike; and when this does occur, they make gawky-looking plants.

Buxus in variety roots easily, as cuttings taken in February and March, and inserted in soil surfaced with sand, well watered-in with a rose water-pot, and covered with a bell-glass. The cuttings should not be longer than 4 inches, 2½ inches being placed beneath the soil. The Minorca Box, *Buxus Balearica*, takes so long a time to root, that it is best to layer it; while *Buxus elegantissima*, and its variegated form, as well as the creeping Japanese Box, can be increased by pegging down the branches, and covering them with prepared soil so as just to leave the short laterals showing through the surface, and shading the bed with any convenient material, so as to keep the soil in a uniformly moist state.

Cytisus, which may be classed with shrubs, are raised from seed or cuttings, while the tree-forms of *Laburnum* are increased easily from seed, or by grafting on the common variety. The white-flowered species, called in nurseries White Portugal Broom, is one of the most pretty of summer-flowering trees, either on its own roots, or grafted standard high, and contrasted with the Spanish Broom (*Genista juncea*), or the rush-twigg'd Broom, makes a very telling subject in the shrubbery. This is easily raised by seed, or by means of cuttings of the mature shoots; or the young growth may be taken and struck under a bell-glass in a close pit. Thus treated, it is easy to strike all the low-growing forms of *Cytisus* and *Genista*, as *elongata*, *purpureus*, *nanus*, &c., as well as the lovely novelty lately introduced from the Balkan Mountains, and called, from the pass where it was found, *Schippkensis*. This, in its season, is covered with beautiful large white flowers, which, being terminally produced, makes it a fine plant for cutting and table decoration.

Desmodium and *Coronilla*, close allies of the Brooms, may all be propagated by cuttings of the young wood, taken just as growth is completed, either with or without a heel, inserted in sandy soil, and covered with a bell-glass; and the same may be said of the double-flowered Gorse, and the Spanish variety (*Ulex hispanica*), so useful as a decorative plant, or on the margins of shrubbery banks, while the double form of the Dyer's Broom (*Genista tinctoria*) strikes freely.

Deciduous Shrubs, as *Deutzia*, *Diervilla* (*Weigela*), *Hydrangea*, *Ribes*, *Philadelphus*, and most of the *Spiræas*, can be raised in the open from cuttings of stout, mature shoots, bedded-in close together in a north border, and protected from frost in the winter by cut branches of Spruce Fir, scattered over and among them. This should be done in early autumn, before all the foliage has fallen off, when, if the season be mild, they will callus and root freely in the spring, and be ready to "quarter up" in the following autumn.

St. John's Wort (*Hypericum*), the same may be

said of all these, of which perhaps *Moeserianum* and *patulum* are the finest of recent introductions. *Experience*.

(To be continued.)

THE HERBACEOUS BORDER.

MICHAELMAS DAISY "ELLA."

At the Shrewsbury show this year I was standing by, when an exhibitor of hardy-flowers was asked by a visitor, "What is the best Michaelmas Daisy?" He replied, "Robert Parker;" and considering that it nearly represents the best form of the original Michaelmas Daisy, *Aster Novi Belgii*, he was perhaps not far wrong. But as sponsor to Robert Parker, I was rather pleased with the selection. It is about twenty years since I found this plant growing in Robert Parker's nursery at Tooting, labelled *Aster amethystinus*, and I took it home and re-named it; and from my garden it has found its way to nearly every nursery in the kingdom. But about ten years ago, I found a seedling of which Robert Parker was evidently the seed-parent. It became *Matre pulchra* *Alia pulchrior*, and I named it "Ella." This, too, has found its way to most nurseries, and I consider it the best of its class. It is 6 feet high, and has much the habit of its parent, flowering about a week later. The flowers are better shaped, and have twice as many rays. When it first opens, the colour is little better than the slate-grey of *R. Parker*; but after a few bright days, especially if the nights are frosty, a condition favourable to the colour of nearly all the tribe, the rays acquire a rich glow of amethystine-purple, which lasts in successive flowers till severe frost brings the season to an end. *O. Wolley Dod*, *Edge Hall, Malpas*.

BETTESHANGER.

A PLEASANT journey from Ramsgate, on the Dover road, brings the traveller to Betteshanger, the seat of Lord Northbourne. The place is distant 5 miles from Sandwich. After leaving Sandwich, the road passes through extensive orchards of Damsons, Plums, and Pears, and farming-land, carrying in some places market-garden crops, on one farm, a 40 or 50 acre field was remarked, which had been planted with Potatoes, with Brussels Sprouts set out in the furrows.

Plums were not generally an abundant crop in any part this year; but although this district had somewhat suffered from spring frosts, its contiguity to the sea had served to mitigate the severity of the cold, enabling some cultivators of Plums to save half a crop certainly, and the fact of the fruit being scarce elsewhere, greatly enhanced the prices obtainable by growers in this neighbourhood and further a-field.

With the knowledge born of necessity, the fruit-cultivators when they came into possession of the land at once allowed the quick-set hedges dividing the fields, and bordering the high road, to grow upwards to a height, in some instances, of 15 feet, but without adding the least to their width. The hedges are rendered rigid by means of stout wire fastened to poles, to which the shoots are secured. These tall, thin ghosts of hedges were formed by these simple contrivances into capital wind-breaks without much cost.

The road for the last mile or so rises rapidly, with a sharp ascent into the park from the main road, passing through young plantations of mixed timber trees, Conifers and Oak predominating. The park itself possesses plenty of fine old trees, including many Oaks, which seem quite at home on the strong loam overlying the chalk. The surface is undulated, and most kinds of timber attains to large dimensions; and amongst Conifers remarked we may mention the Lebanon Cedar, which grows here with remarkable vigour. The Yew likewise grows with rapidity; and in this connection mention should be made of two Yews planted in the churchyard by Sir Walter James, the first Lord Northbourne, and Mr. W. E. Gladstone in commemoration of a visit the latter made to the place in 1857. In the forty years

that have elapsed, the then tiny trees have reached a height of 18 feet, the one with the stem diameter of 10 inches, Sir Walter's tree being slightly the bigger. A slate slab forms a seat between the two trees, and records the event in appropriate verse—fitting arboreal memorials to keep evergreen the memory of two celebrated men. The church itself is a small structure, that stands on the foundations of a very ancient one, and which has been rebuilt from the ground-level at the cost of the family. It stands on a knoll in the park at a short distance from the mansion, and is a strikingly ornate, abundantly-lighted building.

A tour of inspection with Mr. Salway, the head-gardener, as guide, showed that in the matter of flower-gardens, these were not, as is usual, confined to one, and that near the dwelling—but there were three or more. One of these is situated on a series of terraces, each terrace being planted differently, but in all of which tuberous Begonias, in mixed colours and double and single-flowered varieties, are largely employed. To serve as dot plants there were noted *Abutilon Thomsoni variegatum* and *Salvia patens* in large clumps. A draw-well, with handsome well-top and arch of ornamental hammered iron for supporting a pulley wherewith to hoist the bucket, is a conspicuous object in the middle of this garden. The intention was, of course, to furnish water for the supply of this particular garden; but as five men are required to work the pulley and manipulate the bucket, it is put aside in favour of more economical methods. On one or two of the terraces espalier Pear trees are planted by the sides of the grass-walks, the object being the attainment of the bright autumnal tints of the foliage of the Pear in union with the colours of the flowers in the beds, an object which is, we believe, seldom realised, the Pears persisting in dying off in the usual tints of yellow. Hardy herbaceous perennials were found in various parts to the exclusion of tender species, and already several borders and prominent corners are planted with these plants. They also fill two long borders in the kitchen-garden.

A garden of Roses is in contemplation, the species and varieties to be planted being those of robust growth, such as *Rosa rugosa*, in variety: Lord Penzance's hybrid Sweetbriar, Crimson Rambler, the Boursault, and Prairie Rambler, and Roses of this character. A garden planted after this kind would doubtless have a charm of its own for the short space of time such varieties remain in bloom; but unless there are beds of Teas and Noisettes to carry on the floral season till the autumn, it will, we should say, be devoid of interest after the chief flush of bloom has come and gone.

Most of the glasshouses are erected in and about the kitchen garden; a clump of houses, however, stands in the pleasure-grounds at about 100 yards distant from the house. This consists of a conservatory, a fernery, orangery, and a store-house for Myrtles. The conservatory at the time of our visit was enlivened with such annual plants as *Celosia pyramidalis*, *C. cristata*, Cockscombs, *Coleus*, *Pelargonium*, *Petunias*, and the like. The fernery is abundantly planted, and every plant was vigorous and healthy, the effect being natural and good. Rock-work is used to face the walks and furnish spots on which Ferns can be planted; and a pool in which goldfish disported beneath a tiny fountain, added a little life to the scene.

The Myrtles to which we made allusion above are big bushes of several stems, and chiefly remarkable from the fact that they have been raised from cuttings made from sprigs taken from the wedding bouquet of the present Lord Northbourne's mother. The bushes measure 8 feet in height from the tub, and average 6 feet in diameter of crown. Originally there were six of them, but these, from one cause or another, have been reduced to four. The orangery contained a number of Orange-trees of different varieties that fruit well every year.

Wall-fruits were plentiful this year, and very fine crops were noted of Pears, Peaches, Nectarines, and some varieties of Plums. The trees of all kinds, and especially the Pears, are magnificent examples of

good training, and some of them are 14 feet high, and 30 feet wide. The Peach-blister was very prevalent here, as in many other gardens. The Gooseberry-bushes had rendered a good account of themselves, for the crop had been enormous, and some varieties were still ungathered (August 25). There are several vineries containing good crops of excellent Grapes, and a wall-case for Peaches, of which enormous fruits of the pale-coloured Princess of Wales were remarked. The garden is well found in pits for forcing and plant-growing, and a few Orchids are cultivated successfully, as *Cypripedium*, *Calanthe*, *Dendrobium*, &c. It was a pleasure to observe how well Mr. Salway cultivates the now somewhat despised *Achimenes*, and to see capital *Gloxinias* so late in the year. The *Chrysanthemum* receives considerable attention, and numerous plants were remarked which were being grown for the production of specimen blooms. A stove was filled with a quantity of foliage-plants of small size, and it was evident that much indoor decorative work was done. We came away feeling that Betteshanger is a very charming, unconventional sort of garden, surrounded and embellished by noble trees, both indigenous and exotic, and ably managed by his lordship's gardener, Mr. Salway.

SECOND CROP OF OAK.

THE illustration (fig. 86) represents one of a number of examples of stoolled Oaks, that not long since existed in the Wharfedale Woods. I had it left as an example where one of the railway fires had ravaged the wood. The tree has been scorched several times by fires, and one limb was so charred that it had to be cut off. There were six poles on the stool originally. I consider the tree a good example in its way. The old stool shows that a big tree had been cut from it, and the second (present) crop of poles shows very well how clean and straight they grow up in a dense wood, as was once the case, where the tree stands. Such Oak poles are very saleable, and fetch about 10d. per foot standing at the present time, and sometimes more. Such straight clean examples rive well for spokes for wheels, and are bought for "spoke-wood." I once saw on the continent some hundreds of acres of such stoolled Oaks, but from three to four poles to a stool was the maximum; they were fine, however. *J. Simpson, Wortley.*

FORESTRY.

I THINK that a good deal of nonsense is sometimes talked about the management of German forests, as if it could be generally adopted with advantage in England. In the case of many kinds of trees, to grow them close together would be most wasteful; for instance, I see Spruce Fir quoted as a tree to be so grown. What does anyone suppose that a wood so grown for forty or fifty years would be worth an acre? I remember such a wood here, forty or fifty acres, forty or fifty years old, that had never been thinned, and as clean as a German forest. The great gale of January 7, 1839, blew the whole of them down, not up by the roots (they might then have been worth something, though very little), but broke them all off in the middle, so that there was nothing left to pay the expense of clearing the ground. But let no one imagine that under any circumstances, or at any age, such a wood could have paid. English-grown Spruce is good for very little; even Norwegian white deals, grown in a totally different manner on mountain-sides, are hardly fit for building-purposes; but the wood I mention never could possibly have paid a tenth-part of what it would have cost, in planting and rent of land and interest. So again, the Beech-forests they describe; if such were grown in England, they would pay nothing at all for fifty or sixty years, whereas the Buckinghamshire Beech-woods (which are natural forests, and managed as such) pay, I believe, 8 or 10 per cent. an acre yearly. Then to grow Oak unmixed is most wasteful. Young Oaks are good for nothing—remain so until there is 4 or

5 inches of heartwood. At what age will an Oak-wood pay for planting, cost of management, rent, and interest? One thing seems to be forgotten entirely, which is, that given a certain quantity of timber, produced per acre, the fewer the number of trees that produce it, the greater the value of the

FIG. 86.—SECOND CROP OF OAK.

timber produced; besides which, I have no doubt (although it would not be easy to prove it) that the amount of timber produced by trees so close that there is only a flat surface of foliage at the top, is considerably less than when each tree has a cone of foliage for, say, one-third of its height, and had a bare stem for two-thirds of its height. No doubt, most woods in England might be better managed—every

different kind of tree, and every different mixture of trees requires a different management; but we shall not make them pay by trying to imitate what no doubt pays on the mountains of the Black Forest. *C. W. Strickland.*

VEGETABLES.

VEITCH'S EXTRA EARLY FORCING CAULIFLOWER.

Of this capital variety I grew one year nearly 400 plants in 7-inch pots, sowing the seed on December 20. The first heads were fit for cutting in the first week of April; and afterwards the stumps produced strong sprouts. Those plants on which sprouting occurred were planted out of doors, and gave four compact Cauliflowers at the beginning of June. It is a capital variety to withstand drought, remaining fit for use longer than any other variety that I have grown, excepting Autumn Giant. I have grown it extensively for four years, it being the Cauliflower for a gentleman's table, the heads being quite white, close in texture, and agreeable in flavour. *W. Davies, Nidd Hall Gardens, Yorkshire.*

CULTURAL MEMORANDA.

ALLAMANDAS.

I FIND that Allamandas are plants easy to grow when given a sunny position in a stove, and the shoots trained thinly on a trellis. If grown in a border, this should consist of sound fibrous loam, coarse sand and leaf mould, about four-fifths of the first to one-fifth of the last-named ingredient; and, of course, the drainage should be efficient. If the border be well made, it may even form part of the path, and be much trodden upon without any ill effects to the plants. After a few seasons succeeding the planting, when the soil is giving out, liquid-manure should be afforded during the summer. This manure may consist of fresh sheep-dung and soot, stirred together in a barrel, and allowed to clear before being used. Any artificial manure that may be applied in the absence of the former, should consist of very mild doses at long intervals of time, injury to a plant soon following excessive use of these things. Allamandas should be kept rather dry at the root in the winter season, but not so much so as to cause shrivelling of the shoots. I prune our plants somewhat hard back in the early spring. Cuttings root freely at almost any season in a brick bottom heat. During the early years of an Allamanda's life, the soil used for them may be rather lighter than is advisable in a border or flowering-pot. When the flowers only are used in decorations, they should be placed in water two hours before mounting them, afterwards securing them to bits of smooth shaven sticks, with a little bunch of moistened cotton-wool at the base, and they will keep fresh for some length of time. *H. Markham, Northdown, Margate.*

THE FORESTRY SCHOOL AT NANOY.

THE pupils of this school, which may be called a technical university, are recruited from the pupils of the Institut National Agronomique of Paris. About twelve students are admitted every year, each pupil receiving an annual honorarium of 1,200 francs (£48). The total number of externe pupils since the foundation is 308, of whom 34 were French, 83 English, 56 Roumanians, 39 Poles and Russians, 38 Belgians, 20 Swiss, 40 Luxemburgers, and 10 Portuguese. The number of French students (internes?) is given as 1394. The forestry museum is situated in a garden which, though unpretending, forms a great contrast to the adjacent botanic garden in the Rue Catherine. The museum contains minerals and other geological specimens, illustrations of woods of many kinds, showing their natural structure, the effects of various in-

juries and fungal diseases, the modes of cutting timber to advantage, and of utilising it in various ways. The museum seems to be organised in an excellent manner, and next after Kew is the best of its kind we have seen. At one time students destined for the forest service in India were allowed to avail themselves of the excellent academic training given here. The establishment of the forestry school at Cooper's Hill has rendered this less necessary than formerly. Not far from Naney is a vast area of woodland, where the practical teaching of forestry is carried on.

THE WEEK'S WORK.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton Hoo Park, Luton.

Herbaceous Calceolarias.—These beautiful plants should now be slowly growing in 48's and large 60's, and be similarly treated to the Cinerarias; both detest fire-heat, and should not be exposed to it unless the weather is so severe that they can no longer be properly ventilated and exposed to sunlight in cold-pits. Keep them near to the glass. In the warmer parts of the country, especially near the coast, Calceolarias are admirably grown in low pits and ordinary frames till such time as they show flower after being shifted into their flowering-pots at a later date. No stimulus to growth is needed by them whilst small, that is, if the potting-soil be of the right sort; and they should not lack water at the root.

Camellias.—These plants, whether growing in pots or planted out, should at this season be kept well supplied with water at the roots, or the buds will drop. The leaves may be sponged with Fir-tree oil, mixed with rain-water in a wooden pail of the strength recommended by the makers. This will kill white-scale, which in some gardens is very prevalent on these plants, and which secrete themselves about the axils of the leaves, and round the flower-buds. Camellias, if very thickly set with flower-buds, should have some of them thinned off, one or two good buds on a shoot being sufficient. Keep the house cool, and afford the plants nothing that will cause them to grow.

Chrysanthemums.—Excepting in the case of those which will flower the latest, the use of manure-water, &c., should be discontinued. The side-shoots should be removed whilst quite small, and water should be afforded in sufficient quantity to moisten the soil throughout. If mildew and damping-off occur, the plants must be examined every morning, dusting the leaves with flowers-of-sulphur for the mildew, taking care this is thoroughly done. If damping of the early flowers is noticed, the air of the house must be kept drier, air being admitted freely when there is no fog or rain. When Chrysanthemums are stood on Peach-house or viney-borders, damp is sure to prove troublesome. As a means of checking the evil, pots or pans containing large lumps of unslaked lime should be placed at intervals of 6 feet, replacing the lime with fresh as soon as it gets slaked with moisture.

Tuberose.—As these bulbous plants commence to open their flowers, all the light possible should be afforded them, and the plants placed almost close to the glass. The temperature of the pit or house may be kept at 60° by night, and 65° by day, syringing the lower leaves in fine weather, in case red-spider should seize upon them.

Bulbs.—Let all sorts of Dutch bulbs be examined about once in ten days, removing from the coal ashes those that have made a considerable growth of roots, placing them in a slightly shaded frame, the forwardest, if desired, being placed in a forcing-pit.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Selecting and Ordering Fruit Trees.—Orders should be prepared for fruit-trees to replace unproductive orchard, wall, or espalier trees, or to plant in new positions. Lack of fertility in the trees may be due to one or several causes: the trees may have become too old, or they may have been neglected, or the soil is impoverished, or the trees were planted in unsuitable land. In the case of aged trees, or trees that are barren through the roots having reached uncongenial soil, root them out, and plant in their stead clean, healthy, vigorous trees of sterling varieties. Young

vigorous trees may be unproductive through neglect, and the branches may have become infested with lichen. In a future Calendar reference will be made as to the best practical method by which to treat such. In the meantime, a list of approved varieties of the several kinds of fruit to grow may prove helpful to many new readers of the *Gardeners' Chronicle*.

Apples.—Dessert: Mr. Gladstone, July Pippin, Red Juneating, Beauty of Bath, Lady Sudeley, Irish Peach, Devonshire Quarrenden, Kerry Pippin, Worcester Pearmain, Red Astrachan, Blenheim Orange, Cox's Orange Pippin, Margil, King of the Pippins, Ribston Pippin, Bowhill Pippin, Cockle's Pippin, Peasgood's Nonsuch, Mannington Pearmain, Old Nonpareil, Claygate Pearmain, Beauty of Kent, Rosemary Russet, Fearn's Pippin, Court Pendu Plat, Sturmer Pippin, Hornmead's Pearmain, Lord Burleigh, Duke of Devonshire, Golden Reinette, May Queen, and Boston Russett.

Apples: Culinary.—White Transparent, Early Julien Keswick Codlin, Duchess of Oldenburg, Lord Suffield, Pott's Seedling, Cellini, Lord Grosvenor, Northern Dumping, Ecklinville Seedling, Stirling Castle, Emperor Alexander, Frogmore Prolific, Golden Spire, The Queen, Gascoyne's Scarlet (a grand new Apple), Peasgood's Nonsuch, Blenheim Orange, New Hawthornden, Lord Derby, Golden Noble, Bismarck, Warner's King, Striped Keeping, Mère de Ménage, Royal Jubilee, Wellington, Lady Henniker, Lane's Prince Albert, Annie Elizabeth, Hambling's Seedling, Newton Wonder, Northern Greening, Norfolk Beaufin, Sandringham, Hambledon Deux Ans, and Duke of York.

Pears.—Beurré Giffard, Early Benoist, Doyenné d'Ete, Jargonelle, Souvenir du Congrès, Clapp's Favourite, Williams' Bon Chrétien, Beurré d'Amanlis, Eyewood, Durondeau, Marie Louise, Pitmaston Duchess, Beurré Superfin, Conseiller de la Cour, Beurré Diel, Doyenné du Comice, Easter Beurré, Zephirin Gregoire, Josephine de Malines, Glou Morceau, Le Lectier, Beurré Rance. Stewing Pears, Catillac and Uvedale's St. Germain.

Plums.—Rivers' Prolific, Dennison's Superb, Old Green Gage, Orleans, Kirk's Blue, Washington, Jefferson's, Coe's Golden Drop, Golden Transparent (Culinary), Belgian Purple, Rivers' Czar, Grand Duke, Prince of Wales, Victoria, Monarch, and Pond's Seedling.

Cherries.—Bigarreau Amber Heart, Bigarreau Frogmore Prolific, Early Rivers, White Heart, Black Heart, Black Tartarian, May Duke, and Morello.

Peaches.—Early Alexander, Waterloo, Hales' Early, Early Grosse Mignonne, Diamond, Crimson Galande, Violette Hâtive, Royal George, Prince of Wales, Princess of Wales, and Sea Eagle.

Nectarines.—Early Rivers, Lord Napier, Elruge Pine-apple, Dryden, and Homboldt.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Late French Beans.—Where seed was sown in beds in cold pits or frames for furnishing a late supply of Beans, air should be admitted whenever the weather is favourable for doing so, and in such volume as to ensure its circulation among the plants. As long as the present mild weather lasts there will, of course, be no difficulty, but it is during frost that much greater care will be required. At night, let the glass be covered with mats, double or single, as may be needed; or, failing these, with dry litter or bracken. Plants left to ripen seed may now be pulled up by the root, tied in bundles, and hung in a dry, airy shed till dry, the thrashing or shelling-out the seed being reserved for winter work. Pods left on Runner Beans may be gathered and spread out thinly in a warm pit or on a greenhouse stage, so as to become thoroughly dry before being put into the seed-room, shelling-out being done in bad weather.

Cauliflower.—Such Cauliflower plants as are not yet forming heads may be lifted on the approach of frost, and planted rather close together in a cold pit or frame, and have plenty of air afforded in the daytime, and protection at night. By such means, and if they were lifted with a ball, useful heads may be secured for weeks or months after the outdoor supply has come to an end. Young Cauliflower plants planted in hand-lights or in frames should be hardly treated, not coddled, coverings being put over the glass only in the event of very hard frosts being experienced. Autumnal frosts do no harm, and it is

scarcely necessary to use the frame-lights or the tops of the hand-lights if these be removeable, unless during heavy rains. Dust quicklime, or lime and soot, on the soil between the plants, and hunt for slugs, and stir the surface once a fortnight.

Onions.—The autumn-sown Onions are now growing somewhat freely, and will need thinning pretty severely, the bed hand-weeded, and the surface loosened with the hoe whenever it sets after a fall of rain, a battered surface not being conducive to progress. If young Onions are often required in salads in winter, a pinch of Onion-seed should be sown in a box at intervals of two or three weeks, the box being placed in a Cucumber-pit or warm greenhouse till germination takes place, and then removed to a shelf near the glass in a slightly cooler place. A good variety for sowing is the Silver-skin, it being mild in flavour, and nice in appearance. If exhibition bulbs are required next year, a piece of ground should now be selected, on which the crop may be grown. Some soils are adapted for growing Onions with but little preparation beyond deeply digging, and leaving the surface rough during the winter; but most soils require to be trenched two or three spades deep, according to depth of staple, and to have incorporated with each layer good farmyard-dung in considerable quantity; and should the subsoil be stiff and retentive, coal-ashes, burnt garden-refuse, and the rougher parts of the garden-dunghill may be put evenly into the bottom of the trenches.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leicestershire.

The Pinery.—The plants, if they are not already placed in their winter quarters, should now be arranged as previously advised, keeping the plants with ripening fruit and those which will soonest succeed them at the cooler end of the fruiting-house; and those in the intermediate stage should be put together at the warmer end. Afford the fruiting plants water but sparingly, but let it be sufficient to thoroughly soak the ball, as dryness in the soil at this stage will stop the development of the fruit, and cause premature ripening. The plunging materials, if these consist of tree-leaves or bark, will doubtless require partial renewal, and so much new material as may be considered necessary to keep up a bottom-heat added to the old, and well mixed with these. The top-heat may range from 80° to 85° by day, and 70° to 75° by night.

Succession-houses.—Those plants which will be started early in the new year should now be at rest, and receive very little moisture at the root, but not kept so dry as to induce premature fruiting; the temperature of the house should be allowed to drop to 70° to 75° by day, and 60° by night; the bottom-heat being kept at about 75°. One damping-down daily will suffice, and there must be no overhead syringing. If these plants are plunged into a firmly-made hot-bed which is not permitted to get warmer than the figures given, not much will remain to be done till the time to start them arrives. Later successions will have nearly or quite completed their growth for the season, requiring much the same kind of treatment as the others, always taking care that they do not get too wet after being dry, and then excited a little, or they will all or many of them throw up before their time. These remarks apply particularly to Queens. Most of the suckers will have finished growing, and moisture and warmth may be gradually reduced, in order to lessen growth at the duldest part of the year, and prevent drawing. Do not keep suckers crowded together, but let them have space, and be placed close to the glass without actually touching it. If any variety is scarce, and strong suckers are available, they may be potted and plunged round the edge of the bed, in the fruiting division, as elsewhere, if a bottom heat of 90° be available. Keep the glass as clean as possible, and put a light covering over the roof on frosty nights, in order to keep up the temperature, and prevent moisture condensing on the glass.

Strawberries.—See that all plants are plunged in leaves or coal-ashes, as well as protected from rain. Where very early fruit is required, a start should be made forthwith, remembering that by introducing plants into mild heat, more plants are required for furnishing fruit at an early date than later. Have the forcing-pits and houses thoroughly cleaned, and select the best-ripened of those growing in 48's, washing the pots, and cleaning the surface of the soil, and the crowns; afterwards dipping each plant overhead into a mixture of water 3 gallons, soft-soap 2 oz., and flowers-of-sulphur 2 oz. The plants

may be stood on boards placed on a firm bed of fresh tree-leaves to start, taking care that the leaves have been well mixed together, and space is left under the lights for the escape of the moisture generated by the fermentation of the leaves. The degree of warmth may not at the beginning exceed 45° by night, and by day 50°. Top-heat from hot-water pipes will not be necessary at this season if a leaf-bed be employed, and the plants may stay in this pit till they show flower. Water must be very carefully applied, for owing to the damp surroundings, the evaporation of water from the soil will be very small in amount.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorset.

The East Indian-house.—The beautiful and rare species *Bollea coelestis*, B. Lalandei, B. Patini, *Pseudestrea cerina*, P. Rozzli, P. Klabochiana, P. Lehmanni, *Batemanniana* Burti, B. Colleyi, and *Hemiteya meleagria*, now making growth freely, should be placed at the coolest end of this division. To be successful with these, the air around them should be kept moist allways, and the compost never allowed to become dry. At Burford the plants are placed upon shallow pans, and a layer of sphagnum moss about 3 inches thick between the sides of the pots, so that in time a bed of living sphagnum-moss forms. Notwithstanding moisture thus afforded, the undersides of the leaves become infested with red spider, which causes the foliage soon to turn yellow and drop off, if not freed from the acarid betimes. The north side of the house, where plenty of light is obtained, is a good place for these plants, for in no case may they be exposed to direct sunshine.

Deciduous Calanthes will soon be coming into flower, rendering it advisable to discontinue affording the plants manure water, clear rain-water being alone afforded when water is needed. When the flowers begin to expand, the amount of water should be gradually lessened, and withheld entirely by the time half of them are unfolded. These plants may be exposed to full sunshine, in order to ripen the new pseudo-bulbs, and that the colours of the flowers may be clear and distinct. As the plants mature, the tips of the leaves turn brown, and although this is unsightly, the brown parts must not be removed. The foliage must not be so placed that it touches the roof-glass, as changes in the night temperature are soon felt by the plants, causing the foliage to turn black and fall prematurely. The temperature for *Calanthes* should be kept at 65° till half of the flowers have expanded, when a drop of a few degrees is beneficial.

Epidendrum bicornutum.—This pretty plant should now be growing freely, and occupying a place at the warm part of the house. Avoid placing it, or *Galeandra devoniana*, near the roof-glass during cold, frosty weather.

Grammatophyllum Ellisii.—Plants which have made their growth may be removed from the warmest to the coolest part of the house, and afforded just enough water at the root to prevent shrivelling during their rest.

Phalaenopsis.—The species *P. Schilleriana*, *P. amabilis*, *P. grandiflora*, *S. Stuartiana*, *P. leucorrhoda*, and *P. Sanderiana*, being now comparatively at rest, although still making roots freely, require careful attention in the matter of affording water at this season, an excess being dangerous to their health. The sphagnum-moss should be allowed to become crisp on the surface, and of a whitish colour before affording water, and dipping the basket, &c., should now not be practised; rather sprinkle the sphagnum and the sides of the basket with a fine rose-can, allowing no water to get into the centre of the growths.

Cattleya-house.—The *Pleiones* (or Indian *Crocuses*) are now making a pretty display in this division, and in order to have them in good condition for as long a time as possible, no water should be afforded at the root, or any moisture allowed to fall on the blooms. *Pleione*-flowers last longest when the plants are used for indoor decoration, the dry air of a room conducting likewise to the giving of the plants a short rest.

Vanda.—The tricolor and *suavis* sections of *Vanda* will soon require repotting, &c.; and during the coming week it will be advisable to let the plants get moderately dry at the root, they being in that state less liable to receive a check, and more easily managed.

Odontoglossum citrosimum.—This plant is fast forming new pseudo-bulbs, and needs a place near the roof-glass of the Cattleya or intermediate-house, where there is full exposure. The more backward plants may be placed in a light, airy position in the East Indian-house. From the time the new pseudo-bulbs begin to form, afford the plants plenty of moisture at the root, till growth is fully made up; encourage early growth, in order to ripen it properly before the winter commences.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maidenhead.

Herbaceous Borders.—The perennial *Asters*, or *Michaelmas Daisies*, are the chief attraction during the present month. The flowers are attractive in a cut state, and they are not injured by slight frosts. These hardy plants require only a moderately good soil and applications of water during dry summer months, and they are sure to give satisfactory results. The stock may be increased by division as soon as the plants have flowered, or if allowed to remain until the spring, they may be readily propagated in quantity from the young growths that are then thrown up. While the majority of the plants are still in flower, examine the stock with a view to the selection of the best and most distinct varieties, that the rest may be discarded. The following list includes a good selection of early, mid-season, and late flowering varieties:—Early: *acris*, dark lilac, very free and compact, 2 feet; *Amellus major*, deep violet, one of the best, early and dwarf, 2 feet; *cordifolius*, soft mauve, graceful, 2½ feet; *Novi Belgii* Harpur Crewe, good white, 4 to 5 feet; *Purity*, white, 5 feet; *lævigatus*, rosy-pink, dwarf and compact, 2 feet; *lævigatus Orion*, a slightly deeper-coloured form than the preceding. Rather later are *Nancy*, pale blue, very good, 3½ feet; *John Wood*, white, 4 feet; *N. B. densus*, soft blue, compact head, 3 feet; *lævia*, deep blue, 3½ feet; *Arcturus*, dark stems with lilac flowers, good, 3 feet; *vimineus*, small starry white flowers, very good, 3½ feet; *Robert Parker*, soft lavender blue, 5 feet; *James*, white, 4 feet; *punicus pulcherrimus*, bluish-white, a strong grower, 5 feet; *ericoides*, small, white, 3½ feet; *cordifolius Diana*, a beautiful variety, bearing graceful sprays of soft lavender flowers, 4 feet. This variety should be planted where slight shade is afforded, in summer the foliage being injured by bright sunshine. Following these are *Flora*, pale rosy-lilac, 4 feet; *paniculatus*, W. J. Grant var., pale lilac, 4 feet; *diffusus horizontalis* and *d. pendulus*, 2½ feet; *Archer Hind*, soft blue, 3 feet; and *Maia*, rosy-lilac, 4 feet. Latest of all are *Tradescantii* and *grandiflorus*, the former having small white flowers and handsome foliage, height 5 feet; and the latter large purple flowers, 3 feet.

Storing Dahlias, &c.—Where it is not convenient to lift *Dahlia* tubers at once, the tops may be cut away to within 8 or 10 inches of the ground, and eventually a fine day should be chosen to lift them. When lifting them, all the soil should be shook away, and the labels securely fastened to the roots with small tarred string or thin wire. It is good practice to temporarily store them for two or three weeks in any spare frames, laying them upside down to allow all moisture to dry out of the stems; they may be afterwards stored in any cool place that is secure from frost. Choice varieties should be kept in boxes, where they may be given special attention. Failing a better position, the general stock may be safely stored under plant stages holding bedding *Pelargoniums* that require little water during winter, where, if well dried before housing, they will take no harm from the slight drip during the winter months. *Cannas*, *Hedychiums*, *Marvel of Peru*, and *Salvia patens* may be similarly stored, but the tops of these should be only partially cut away at present.

General Work.—*Heliotropes*, *Coleus*, or other tender plants, that have become injured by frost, should be cleared away. A beginning may be made to dip and re-plant with spring-flowering or foliage-plants to be used for winter and spring decoration. Summer-bedding *Violas* should be trimmed of the longest flower-growths, and if the plants are allowed to remain, they will bloom freely in early spring. Where blue or purple varieties have been used in mixture with variegated *Pelargoniums*, the latter may be removed, and yellow *Wallflowers* or white *Hyacinth* bulbs be substituted; while *Myosotis dissitiflora*, *Nemophila insignis*, or similar subjects, may be associated with white-flowered *Violas*. All *Daffodils* and early-flowering bulbs should now be put into the ground as soon as possible. Box-edgings may be re-

laid at this season, or during the next week or two, if it is necessary to relieve the pressure of work which occurs in the late spring months.

THE APIARY.

By EXPERT.

The Feeding of Bees.—Winter is not far ahead, and before long the sugar-candy pot will be bubbling in many a beekeeper's kitchen. But those of us who, like the writer, are bound to keep their apiary within moderate limits, must have been obliged after this swarming summer to join up stocks, and they will now perhaps possess more stored combs than they care to keep through the winter, useful as a few such combs will be to them next spring. In that case, candy is not wanted, seeing that as good if not better results can be got by using the spare combs in a manner I will now describe, mentioning however, as a proviso, that, although the quality of the honey is of small consequence, and the presence of pollen in the cells in reasonable quantity is no objection, the comb itself must be such as you would care to retain in your hive brood-nest. Take two empty frames, call them top and bottom respectively; tack a piece of thin board to the side bars of the top frame, so that one face is quite or pretty nearly covered over. Put the bottom frame flat on a table, then the comb frame accurately on top of it, and on the top of that again, the top frame boarding upwards; twist pieces of frame-wire round the frame ends and bottom bars, so that the frame will keep in position. Here then is a snug honey-box with stores in the middle and a winter passage below, so that the bees can move about or cluster as they will. Place it over the brood-nest, and cover with soft quilting material of any kind available. If the brood-nest is very big, the honey-box can be placed transversely; but probably it will be better to place it so that frame-ends cover frame-ends, to which there is no practical objection if the quilting be properly seen to. Having done this last winter, I left the hive alone till the middle of March. On inspection I found that the honey had been consumed; while the comb contained brood on both sides. Three snips of a big pair of scissors set the brood-frame free, and it was at once lowered into place at the back of the brood-nest, which still contained a good supply of stores. After results quite justify me in recommending this method of wintering to such as have combs at their disposal.

Making Hives Secure for the Winter.—Before packing down for the winter, scrape the tops of the hives well, removing every irregularity in the shape of brace-combs or propolis. When all is smooth and straight, give a puff or two of smoke to drive the bees down, and pass a hand-brush rapidly over the top bars. Any scrapings which fell down between the combs can be cleared away when cleaning floor-boards, which latter job I defer till the tops have been seen to; and I would here urge a precaution—do not interchange floor-boards indiscriminately. We have known disease to be spread in this way through the operator being unaware of the presence of foul brood in his apiary. Destroy any quilts that have been propolised and worn out, and arrange top coverings of frames neatly, using some means to keep them close down at the sides. Not fewer than three or four layers of carpet, felt, or clean, dry sacking, should be used when the cork-dust cannot be had. But a few inches deep of the latter material in a box with a bottom of calico, laid on a single piece of carpet or flannel, makes a better winter cover than several layers of carpet only. So long as the bees continue foraging, and prowling about hive entrances other than their own, in autumn, all doorways should be contracted to less than an inch in width, but as soon as the robbing instinct passes away, entrances may be enlarged to 5 or 6 inches, and kept so during the entire winter, only reducing in cases of keen winds and drifting snow. Nothing tends more to keep bees in health than plenty of air in damp or muggy weather. In conclusion we need only urge that roofs be made watertight, stands secure against storms, and all means to keep stocks perfectly quiet and undisturbed during the winter months.

GIRTH OF TREES.—From the current number of *Notes and Queries* we take the following:—"A Willow near the London stone at Chertsey Lock has lately died, after much previous injury by wind and flood, which I believe to have been the largest Willow known. The stump has been measured by Mr. MARSH, the lock-keeper, as 18 feet 4 inches in circumference. D."

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	Oct. 26	Royal Horticultural Society's Committee.
SALES.		
MONDAY,	Oct. 25	Bulbs, at Protheroe & Morris' Rooms. Nursery Stock, at the Nurseries, Sunningdale, Berks, by Protheroe & Morris (three days).
TUESDAY,	Oct. 26	Bulbs, at Protheroe & Morris' Rooms. Continental and other Plants, at Protheroe & Morris' Rooms.
WEDNESDAY,	Oct. 27	Bulbs, at Protheroe & Morris' Rooms. Nursery Stock, at the Cambridge Nursery, Bewlsh Hill, Upper Norwood, by Protheroe & Morris (two days).
THURSDAY,	Oct. 28	Bulbs, at Protheroe & Morris' Rooms. Continental and other Plants, at Protheroe & Morris' Rooms. Nursery Stock, at Hollamby's Nurseries, Groombridge, Tunbridge Wells, by order of the Executors of the late Mr. Edwin Hollamby, by Protheroe & Morris (two days).
FRIDAY,	Oct. 29	Bulbs, at Protheroe & Morris' Rooms. Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—47°.

ACTUAL TEMPERATURES:—

LONDON.—October 20: Max., 62°; Min., 47°.

PROVINCES.—October 20 (6 P.M.): Max., 59°, South-west Ireland; Min., 51°, Aberdeen.

Weather generally fine, foggy in places.

Forest
Reservation.

It is with great concern that we read the following passage in a recent number of *Garden and Forest*:—"Emboldened by the action of Congress in practically revoking Mr. CLEVELAND'S Forest Reservation proclamations, and by the attitude of the administration toward the whole subject of our western forests, the lumbermen now controlling a large block of big-tree forest on the western slope of the Sierra Nevada, in California, are making a determined effort to obtain from Congress authority to cut the Sequoia timber in the General Grant National Park. This particular portion of the Sierra Reservation includes about 1,500 acres, and is covered with an exceptionally fine growth of Sequoias and Sugar-Pines, numbering among its vegetable wonders the great tree known as the 'General Grant.' . . . It is unnecessary to remind our readers that these Sierra Sequoias are marvels of the vegetable kingdom, unsurpassed in grandeur, and probably the oldest living organisms on the face of the globe. Every individual is a monument which should be sacredly preserved for the benefit of future generations. To cut down one of these trees is a crime, and it should be a matter of national humiliation that a considerable part of the Sequoia forest has been allowed to pass from Government control into the hands of lumbermen. There was no excuse for this; there would be less excuse in allowing those portions of the Sierra forest which have already been reserved for the benefit of the people to be opened to entry. The lumber, even, is not needed by the community, which can be

abundantly supplied from the Redwood forests, and no one but a little group of men who expect to make money by this transaction has any interest in the success of this movement."

The West India
Royal Com-
mission.

BLUE-BOOKS, as a rule, rarely come under the cognisance of the general public, and when they do, they do not always prove agreeable reading. They are frequently crammed with details imperfectly summarised, and many of them irrelevant or of subsidiary importance only. Often, too, they are filled up with formal communications recording (let us say by way of illustration) the fact that a clerk in the Circumlocution Office has been directed by his superior to forward to the superintendent of the brick and tile department a scheme for the manufacture of bricks without straw, and to request that the superintendent will favour the superior with any observations on the scheme that may occur to him. The letter is of course acknowledged with more forms and ceremonies, and in due time the superior is made acquainted with the opinion of the superintendent. All this is no doubt very methodical and business-like, but it has no interest for the public, and it is surely a great waste of time and money to print these office details.

A report of the West India Royal Commission now before us is less open to this kind of criticism than similar productions sometimes are. It contains an account of the issue of the Commission, a clear statement of the work it was desired to accomplish, and an equally lucid report of what was done by the commissioners. The main subject of enquiry had reference to the condition and prospects of the Sugar Industry in the West Indies. From well-known causes, to which it is not our purpose to allude in these columns, the growth of Sugar-cane and the manufacture of sugar in the West India Islands is now being carried on under such depressing conditions, that there is reason to fear that the cultivation of sugar will be abandoned, and a very large section of the population thrown out of employment, and left without means of subsistence. The commissioners used all diligence, but we fear it must be said they have not told us much that was not known before. The suggestions they make, so far as they are of a political nature, must be left to the consideration of politicians and statesmen.

In these columns we are concerned chiefly with the question as to what substitutes for Sugar-cane can be provided, and more especially as to what plants can be profitably grown in addition to the cane. There can be no doubt that one of the principal sources of the disastrous condition in some of the West India islands arises from the exclusive cultivation of Sugar-cane. To use a homely phrase, the planters have put all their eggs into one basket, and are now suffering the consequences of their lack of foresight. What then can be done now to remedy this state of things? The answer is by no means wholly unsatisfactory, though time will be necessary to secure the desired ends. The remedy is to supplement sugar cultivation by the addition of other tropical products of which there is an abundance, selecting in each case those which are adapted for particular localities and special requirements. Tropical fruits, Oranges, Pine-apples, Yams, vegetables, spices, perfumes, drugs, dyeing materials, Rice, Arrowroot, endless varieties of fibre-plants, Cotton, Cinchona, Coffee, Tea, Cocoa, rubber, Lily-bulbs, Orchids,

and many other things might be tried according to circumstances. To some extent this has been done, and Jamaica has already a very large fruit-trade with the United States. In some cases trial has been made, but from one cause or another, the venture has not proved profitable. Of course, the cultivation of many of the subjects above-mentioned must be at first experimental, and to secure the success of experiments, experiment stations, directed by competent men, and well provided with all the necessary plants, must be established where they do not already exist.

And this reminds us of the valuable services which Kew has rendered to the colonies since it has existed as a public institution. No sooner was Sir WILLIAM HOOKER installed as Director in 1841, than he began that series of varied labours in the interest of the colonies, which has been carried on by successive Directors with ever increasing energy to the present time. Of late years, in addition to the larger botanic gardens in Jamaica, Trinidad, and British Guiana, which are in direct communication with Kew, and which have always been centres for the growth of economic products and sources whence useful knowledge relating to them was diffused, smaller botanic stations have been established in the scattered islands. To the further development of these we may confidently look for the amelioration of the existing state of things. These stations were established at the recommendation of the authorities at Kew, who devised the scheme of operations, provided the material and furnished the superintendents in the shape of young gardeners trained in the Royal Gardens. In the report before us, the commissioners urge the formation of a special department to supervise, concentrate, and direct into useful channels the work of these several stations, and generally to promote economic botany and agriculture. The department should, according to the suggestions of the commissioners, be directed by a competent officer to be paid by the Imperial Government. This official might organise and supervise educational efforts according to the needs and capabilities of the several islands. Whether such an officer is really needed, it is for those on the spot to determine. It might be thought that one or the other of the existing superintendents, with their long experience and varied information, might suffice, and the garden under their charge be made, to a greater extent than at present, the headquarters of economic botany for the islands. Owing, however, to the distance of one island from another, and the relatively little communication between them, it will be necessary to multiply the stations and increase the number of superintendents. The commissioners estimate the annual cost for the botanic department, scientific agricultural education, and subsidies for steamers plying between the islands and the United States for the conveyance of fruit, &c., at £27,000.

A valuable analysis of the report prepared by the secretary enables the reader to refer readily to any special point, but the most valuable appendix is that drawn up by Dr. MORRIS, the Assistant Director of the Royal Gardens, Kew. Dr. MORRIS, who is specially qualified by early training at Kew, and subsequent experience in Ceylon, Jamaica, Honduras, and other colonies, accompanied the commission in the capacity of technical adviser on botanical and agricultural matters, and he now, within the limits of the work of the commission, furnishes us with an exhaustive treatise on tropical cultivation, and sketches the work already done by FAWCETT, HART, JENMAN, and other botanists in their

several establishments. Chemical analyses by Professor HARRISON, Messrs. D'ALBUQUERQUE, BOVELL, and others, have resulted in an increased production of sugar, and at a diminished cost, whilst selection of canes and the raising of seedlings—the result of comparatively recent botanical discovery—has led to the discovery that some varieties are richer in sugar than others, and less subject to disease. The whole appendix forms a valuable addition to the

the *Index Kewensis* under the original name, hispida. The general appearance of the plant is sufficiently indicated in Mr. W. G. SMITH's drawing (fig. 87) to preclude the necessity of description. We ought, however, to pass on the caution imparted to us, and repeat, "This plant stings." The flowers are of a pale yellow, of a singular form, evidently adapted to fertilisation by some insect, presumably one that knows how to avoid the barbed and venomous hairs on the foliage. These latter would keep off unauthorized intruders.

vision for heating, ventilation, and open tanks through which the pipes pass, so that an adequate supply of moisture is secured. The plants are suspended from the roof, and there are side borders at present utilised for *Dracenas* and decorative plants. No doubt this will form one of the most attractive, as it is certainly one of the most interesting additions to our noble gardens. The new house adjoins the stove-house in the T-range, and is entered from it at the angle formed by the stove and the Victoria-house.

FIG. 87.—*LOASA HISPIDA*: FLOWERS PALE YELLOW.

Some of the barbed hairs are shown magnified 50 diameters, and also one of the glandular hairs of much greater size.

literature of economic botany, and redounds to the credit of the reporter no less than to the establishment of which he is so distinguished an officer.

LOASA HISPIDA.—This is a beautiful annual, for the opportunity of figuring which we are indebted to the courtesy of Mr. LYNCH, of the Cambridge Botanic Gardens. It was originally introduced to the Chiswick Garden sixty or more years ago, and was figured by LINDLEY in the *Botanical Register* (1837), t. 1390, under the name of *ambrosiifolia*; but we must own that the reason there given for the abandonment of LINNÆUS' name do not seem very cogent. We are not surprised, therefore, to find the plant entered in

ROYAL HORTICULTURAL SOCIETY.—The dates fixed for next year's meetings are as follows:—1898: January 11; February 8; March 8, 22; April 12, 26; May 10; Temple Show, May 25, 26, 27; June 14, 28; July 12, 26; August 9, 23; September 6, 20; Fruit Show, Crystal Palace, September 29, 30, October 1; October 11, 25; November 8, 22; December 13. Any gentleman willing to deliver a lecture on any of these dates would greatly oblige by communicating at once with the Secretary, 117, Victoria Street, S.W.

NEPENTHES-HOUSE.—A new house for the cultivation of *Nepenthes* has just been completed at Kew. It is a light span-roofed structure, with ample pro-

NATIONAL CHRYSANTHEMUM SOCIETY.—It is the intention of this society to hold a special Apple competition—open to all, in commemoration of the sixtieth year of the reign of Her Majesty The QUEEN, on the occasion of the Chrysanthemum Exhibition at the Royal Aquarium, Westminster, on November 9 and two following days. There are to be shown twenty-four distinct dishes of Apples, five fruits of each; and nine varieties must be those which were in cultivation in this country in 1837, the remaining fifteen varieties consisting of such as have been introduced during the last thirty years. Mr. R. DEAN, Ranelagh Road, Ealing, will furnish intending exhibitors with full particulars of the competition on application.

THE POTAMOGETONS OF THE BRITISH ISLES.

—The object of this work is to supply a long needed set of good and reliable illustrations of British Potamogetons. Both descriptions (by Mr. ALFRED FRYER) and illustrations (by ROBERT MORGAN, F.L.S.) will include the varying forms and states as well as the generally recognised species. The synonymy, though not aiming at absolute completeness, will be ample for all working purposes. An attempt will be made towards a natural arrangement of the species founded on the changes of form in their progressive stages of growth, rather than on the comparatively limited distinctions afforded by the fruit, illustrations of which will form a special feature. Messrs. L. REEVE & Co., 6, Henrietta Street, Covent Garden, are the publishers.

HORTICULTURAL CLUB.—The first dinner and conversazione for the session 1897 to 1898 took place on Tuesday evening, October 12, and there was a good attendance of members. Mr. HARRY J. VEITCH occupied the chair, and there were present, Revs. W. Wilks, and H. Pemberton, Messrs. Williams, Cockett, L. Pearson, T. Francis Rivers, H. Turner, Gurney Randall, Asbee, Gordon, Geo. Monro, M. Garcia, and Herr Hugo Müller, President of the Pomological Society of Vienna, who was the guest of the Club for the evening; his health was proposed by the chairman. A paper was read by Mr. T. Francis Rivers on "Orchard-houses and Fruit;" an interesting discussion followed, and a cordial vote of thanks was awarded to Mr. Rivers for his excellent paper; this we hope to give in some future issue.

NEW CHRYSANTHEMUM.—At the meeting of the Floral Committee of the National Chrysanthemum Society on the 12th inst., a First-class Certificate was awarded to the variety, Viscomtesse Roger de Chezelles. This is a large sized Japanese bloom, very rich yellow in colour, with petals broad, slightly forked, flat, and incurving. Twelve blooms were shown finely by Mr. W. J. GODFREY, Exmouth.

SAD END OF A MEMBER OF THE KEW STAFF.—Some week or two ago, the pelican, which was a bird with a character, and popular with the visitors, escaped from the gardens. Nothing was heard of it till a few days since, when news reached the gardens that some wretched gamekeeper had shot the bird in Sussex. A later statement tells us that another pelican was shot on the Thames, near Hammersmith. This is more likely to have been the Kew bird than the one shot in Sussex. It seems to be impossible to prevent the indiscriminate slaughter of rare birds, revolting as the practice is to those interested in natural history.

SALIX GRACILISTYLIS, MIQUEL.—This handsome Japanese Willow has attracted much attention at Kew this season by reason of its bold, broadly lanceolate, thickly-nerved leaves, and crowded prominent buds. The catkins measure from 1½ to 3 inches in length, and are very striking. The tree was introduced by Messrs. BARBIER FRÈRES, of Orleans, and a full description of it is given by the late Professor MIQUEL, in the *Ann. Mus. Bot. Lugd. Bat.* (1867), vol. iii., p. 26. MIQUEL speaks of it as a *perdistincta* species. It occurs not only in Japan, but also in North China.

TECHNICAL INSTITUTE, DUNDEE.—Mr. D. T. FISH is to deliver a course of eight lectures on Fruit Culture under the auspices of the Dundee Horticultural Association. The cultivation of the Apple, Pear, Plum, Peach, Nectarine, Gooseberry, Currant, Raspberry, and Strawberry is to be discussed.

JOHN LAING & SONS, FOREST HILL, LONDON, S.E.—These well-known nurserymen desire us to inform our readers that the awards jury of the Victorian Era Exhibition at Earl's Court has just awarded them a Diploma and a Gold Medal in recognition of the meritorious manner in which they have planted the numerous beds in the gardens at that place of resort with flowering plants and shrubs.

NEWCASTLE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.—The monthly meeting of this society was held at 25, Westgate

Road, Newcastle, on Tuesday, October 12. There was a good attendance of members, presided over by Mr. JOHN BULLOCK. Mr. M. LARKE, of North Dene, Gateshead, read an excellent paper on the tuberous-rooted Begonias, embracing their culture both for indoor decoration and for massing in beds. The paper was followed by an animated discussion in which many took part.

STAPELIA GIGANTEA is flowering in the stove at Kew. The species which was illustrated in our columns p. 693, vol. vii., 1877, has not only larger flowers than any of its congeners, but the flowers themselves differ in appearance from those of the ordinary type.

THE LATE MR. WILLIAM SCOTT.—In our last issue we announced the decease of Mr. WILLIAM SCOTT, the director of the Mauritius Botanic Garden, and now give some details as to his career, taken from an obituary notice in the *Stirling Observer*. Mr. SCOTT reached Stirling from the Mauritius about a month ago in excellent health and high spirits. About ten days ago he made the West Highland tour, but on ascending Ben Nevis unfortunately caught a cold, which complicated by an attack of fever and ague, rapidly developed into pneumonia. His parents were highly respected parishioners of Lomnay in Aberdeenshire, where Mr. SCOTT was born on September 21, 1859. On leaving school he entered the service as apprentice gardener of Colonel RUSSEL at Aden House. As journeyman he wrought at Forglen House, near Turrieff, and afterwards at Kippenross. After six months' residence at the Royal Gardens at Kew, he was selected in 1881 for the post of assistant to Mr. HORNE, who was then at the head of the Mauritius gardens and forests. Nine years after this Mr. HORNE retired through length of service, and Mr. SCOTT was immediately appointed his successor. Since then, till his death, he held the post of director of the Royal Botanical Gardens and Forests, many notices of his remarkable successes and accurate professional knowledge having in the meantime appeared in Government despatches, and in the local press. Mr. SCOTT had three gardens in his charge, the largest being Pamplemousses, containing 61 acres, at 228 feet above sea-level. These gardens suffered terribly in the hurricane of 1892, when every leaf was carried away, and, in Mr. SCOTT's opinion, many years will be required to secure for them their former appearance. The second garden is at Curepeep, 1800 feet above sea-level; and the third (which is not open to the public) is situated at Redway, the Governor's residence. In the Mauritius, Mr. SCOTT continued with great zeal the policy of his predecessor in planting forests of Grevilleas, blue Gums, and Casuarinas. The island is said to be comparatively bare of virgin forest, only about 2500 acres of that existing. Already Mr. SCOTT's labours are reaping their reward, for the planters are getting a much improved supply of firewood and of timber for building and fencing purposes. In the interest of the Sugar and Cacao industry Mr. SCOTT busied himself largely. On leaving Mauritius for home, Mr. SCOTT was presented with a sympathetic address from the officers and labourers of the Pamplemousses Gardens.

JUBILEE DRESS OF THE PRINCESS OF WALES.—From far-off Japan we receive the following account:—"The QUEEN'S dress has so often been described and so often pictured, that I will not speak of it; but the gown of the Princess of WALES was described to me by a lady who saw it at the dress-maker's. It was of mauve satin, the shade of a cattleyard Orchid." We spare the reader further details, as not suitable to our columns.

ROYAL TRADESMEN.—Messrs. DOBBIE & Co., of Rothesay Court, Seed Growers and Florists by Appointment, have been permitted to make the addition of the name of ANDREW MITCHELL to the title of the firm.

PRESENTATION AT EASTNOR CASTLE.—Mr. F. HARRIS, who is resigning the charge of Lady HENRY SOMERSET's garden at Eastnor Castle, was the subject of a presentation on the 10th inst., when the garden staff were entertained to supper under the old Vine in the gardens. A gold watch, bearing the

following inscription, was handed to Mr. HARRIS by her ladyship's agent, Mr. W. COLEMAN:—"Presented to FRANK HARRIS by those who have been connected with the Eastnor Castle Gardens during the nine years he has lived there, as a token of respect." Mr. COLEMAN paid a tribute to the abilities of Mr. HARRIS, and spoke to the success he had achieved as an exhibitor of fruit. In a few words of appreciation, Mr. HARRIS acknowledged the assistance he had been given by Mr. BARSON, the foreman, and the staff generally.

SHIRLEY GARDENERS' AND AMATEURS' IMPROVEMENT ASSOCIATION.—The monthly meeting was held at Southampton on Monday, the 18th inst. Mr. F. J. CROOK, Assistant Secretary to the Winchester Gardeners' Association, gave a paper on "Salads," and enumerated a startling variety of vegetables useful for the purpose, stating that gardeners gave insufficient consideration to the subject. The annual outing took place on the 2nd inst., when about thirty members visited the fruit show at the Crystal Palace.

NELSON AND TRAFALGAR.—On October 21, a double number of *Navy and Army Illustrated*, consisting of forty-eight pages, was published in connection with the celebration of Trafalgar Day. This number is a pictorial record of the great Admiral, his life, and achievements. It contains more than 100 illustrations, representing the principal episodes in the great hero's career, or portraits of his companions and contemporaries.

THE REQUIREMENTS OF PLANTS UNDER CULTIVATION.—A correspondent writes:—"Mr. ELWES, in recording the flowering of *Buphane disticha* or *toxicaria*, in his collection, after possessing it for twenty years or more, remarks (p. 270), 'Knowing that the plant was a native of the dry Kalahari desert of South Africa, where the rain is very scanty, the soil very sandy, and the climate excessively dry, I had roasted and starved the plant on a shelf in the greenhouse. When, however, my gardener began to treat it in exactly the same way as we treat *Nerines*, and gave it plenty of liquid-manure during its growing season, the bulb swelled up, became quite hard, and the leaves became much more luxuriant. This year it threw up a flower-spike at the beginning of September.' He then goes on to draw the inference that treating the plant according to natural conditions only resulted in failure, but the adoption of a totally different kind of treatment proved a success. If Mr. ELWES had referred to the *Flora Capensis* he would have seen that this plant grows in four different regions in South Africa—twelve different localities for it being mentioned—and that it also extends to Angola, and the mountains round Lake Nyassa and Tanganyika. Some, at least, of these localities have a very different climate from that described by Mr. ELWES, and it may safely be affirmed that the conditions under which the plant grows in a wild state approach much more nearly to the later treatment described than to the former, which was based upon a misapprehension of the facts. It is perfectly possible for a clever gardener to hit off as it were a successful method of treatment by what is often mis-called empirical means, as in the present instance, but a proper appreciation of the facts would have led to success long ago. There is nothing novel in adopting for this plant the treatment given to *Nerines*. Nature has adopted something pretty similar for ages, as may be seen by a comparison of the localities in which the respective plants grow." [*Buphane disticha*, the old *Hæmanthus toxicarius*, is described with its synonymy in the recently-issued volume of the *Flora Capensis*, by Mr. BAKER, who, as our correspondent rightly says, cites several widely separate and climatically different localities (see BAKER in *Flora Capensis*, ed., Dyer, vol. vi. (1896), p. 242). The first record of its flowering in this country is in *Botanical Magazine*, t. 1257, where it is stated to have flowered in 1809 in the garden of the Bishop of DURHAM, at Mongewell, in Oxfordshire, for the first time, though introduced by MASSON so far back as 1774. Ed.]

PUBLICATIONS RECEIVED.—*Indian Gardening*, a new weekly journal, devoted to gardening and agriculture, edited by H. ST. JOHN JACKSON, and published at Calcutta. We wish it every success, feeling sure that it will, as the promoters say, "fill a want." This first number is full of pro-

CALATHEA SPECIES (MARANTA PICTA, Hort. Bull.)

THIS very beautiful stove foliage plant was shown under the name of *Maranta picta*, at the last meeting of the Royal Horticultural Society by Mr. William Bull. It is a tufted plant, with erect, conduplicate leaf-sheaths, 4 to 5 inches long, each ending in a short cylindrical petiole 1 to 3 inches in length. The blade of the leaf is 9 to 12 inches long, 3 to 4 inches broad, velvety on both surfaces, broadly lanceolate, acuminate, deep green above, with a broad, central, greenish-yellow band running through the centre of the leaf, and branching on each side into alternate, curved, lanceolate lobes cut at the further margin into sharp lobules, like the pinnule of a Caryota, or like the tail of some fishes. The under side is of a rich claret colour.

In Regel's *Gartenflora* (1879), p. 293, is an enumeration of the species, which are arranged in eighteen sub-divisions, according to the nature and form of their variegation. Thus in some the stripes or markings are parallel with the margins and midrib of the leaves. In other cases the markings are transverse, sometimes linear, at other times oval; in fact, showing great variation. The plant before us (fig. 88) does not correspond with any that we find described or figured, but it would be rash to assume it to be new, as the dried specimens in herbaria lose their characteristic markings, and hence it is not easy to refer the cultivated forms to their original types.

HOME CORRESPONDENCE.

ANTHRACITE COAL—Many times you have written recommending the employment of anthracite coal by gardeners in the furnaces. Having moved to the Manor House, Wallington, the landlord allowed me to select certain fireplaces and grates, and quite by accident I selected the slow combustion pattern, that is say, the grate with upright bars and a pull-out frame at the bottom, which is used when an extra draught is required. I found that these grates, which have stone backs, drew with such force that, although the damper at the bottom was in quite firmly, excluding all possibility of air passing, still there was a strong fire. I thought I would like to turn this to account, and I sent into the yard and obtained several scuttles of anthracite coal; this I placed on the fires, and I am very glad to be able to say that it burnt perfectly. Now it is known to all consumers of coal that anthracite is very cheap, not only in its first cost, but also on account of its lasting so very much longer on the fire, and still having a bright glow. I obtained my anthracite coal through Forester of Swansea, but I am not aware that it is of any peculiar nature, neither do I know the name of the pit that it comes from. I wrote to Mr. Forester to tell him of my success in burning the anthracite coal in these grates, and he said it was quite new to him, and he begged me to send him drawings of the grates, which I did. When the fire had exhausted itself in these grates there was hardly any ash left. If you think it of sufficient interest to publish a drawing of these stoves and grates, I shall be very glad to obtain drawings for you, as I consider it rather an important discovery. *Thos. Christy*. [Please do so. Ed.]

FIG. 88.—LEAF OF CALATHEA SPECIES (MARANTA PICTA, Hort. Bull.).

mise, and shows it to be intended as a high-class journal. It contains articles on Horticulture in the Shan States, Horticulture in Mysore, *Cyperus bulbosus* or *seculentus*, *Adiantum Farleyense*, Sabai-grass, &c. —From the Cornell University Agricultural Experiment Station, Ithaca, New York, come the following *Bulletins*:—"Second Report upon Extension Work

WILHELM MILLER; "Notes upon Plums," S. D. WILLARD and L. H. BAILEY; "Notes upon Celery," B. M. DUGGAR and L. H. BAILEY; "Army-Worm in New York," M. V. SLINGERLAND; "Strawberries under Glass," C. E. HUNN and L. H. BAILEY; "Forage Crops," J. P. ROBERTS and L. A. CLINTON; "Chrysanthemums of 1896," L. H. BAILEY and

THE FIRM OF J. R. PEARSON & SONS.—In the review of the horticultural trade for the past sixty years in the issue for October 2, p. 225, Mr. Dean appears to mention our firm as coming into existence in the earlier part of Her Majesty's reign. This is scarcely correct, as our great-grandfather was established here in the nursery business 130 years ago. We believe that there are only three other cases in the trade where a family has carried on business for the same length of time in one spot, viz., Backhouse (York), Dicksons (Chester), and Warner (Leicester). *J. R. Pearson & Sons, Chilwell Nurseries, Notts.*

ABERIA CAFFRA, ETC.—I should like to put it on record in the *Gardeners' Chronicle* that Mr. Thomas Hanbury frequently sends over to this country the fruit of *Aberia caffra*, which he has grown at La Mortola. (See *Gardeners' Chronicle*, Dec. 21, 1895, p. 737, fig. 123). I have now large plants from seed obtained from this fruit. I have also had the fruit in a very fresh state from the Cape. I look upon your No. 564 of October 16 as a most valuable paper. The particulars respecting the planting of fruit-trees will be most welcome to many of your readers. *T. Christy.*

THE KENT MANURE-TRIALS.—Whilst the reports of the manure-trials conducted in Kent by Dr. Dyer are interesting reading, they furnish no indication as to the actual condition of the animal-manure employed in the trials, a matter of some importance, because it is subject to wide variation. The food-strength—or, shall we say, fertilising-strength—of artificial-manure may always be tested by analysis, and the strength or weakness of the sample is as a rule the strength or weakness of the bulk. In the case of animal-manures, any analysis to be exact must be of considerable bulk, and the proportion of plant-food is not easy to determine. If applied to the soil last spring (the soil and season being very dry relatively) in a wet state, or in the condition that is commonly termed fat farmyard-manure, not only would the excess probably of 70 per cent. of water found in it prove of exceeding value in moistening the dry soil, but being in an advanced stage of decomposition, not only would such mineral elements as it might possess be at once available for plant-food, but the fibre found in it would also very quickly become converted into plant-food. All the same, it is well known that such decomposed, moist manures are very deficient in plant-food, and where employed in comparison with good artificials, come out of the test in respect of actual fertility, badly. The moisture in the manure in a dry season has done more good in promoting growth than has the small proportion of mineral food found in it. But if the animal manure is of a fresh description, and applied at once to the soil in its raw state,* whilst the soil thus secures possession of all its plant-feeding properties, yet plants have longer to wait ere these elements can be utilised, both because the manure is much drier, adding little or perhaps nothing to the soil moisture. The dryness of the soil checks decomposition, and thus the whole of a dry season might elapse ere the animal-manure dressing was utilised. That it will be capable of utilisation for a succeeding crop after abundant rains have fallen there can be no doubt; indeed, every one knows that such is the case—artificial manures are readily soluble. Soil must be very dry indeed if the mineral salts found in them do not attract from the soil and the atmosphere enough of moisture to produce fairly quick solution. Thus in dry seasons, whilst excellent yet dry animal-manure containing much fibre, which is latent plant-food, may be in the soil unused by crops, because insoluble for lack of moisture, mineral-salts quickly dissolve, and are thus steadily utilised when wet weather prevails. Minerals, on the other hand, are rapidly washed out of the soil, whilst animal or fibre-manures are fully dissolved and utilised, and are then of greater value than are artificials. The putting into dry soils of so heavy a dressing as fifty loads of animal-manure would, if dry and fibrous, only serve to render the dryness the greater, because exposing the soil so thoroughly to atmospheric influences. If one half, that is the excrementitious portion, were buried, and the long half utilised as mulch, the effect on the crops would be greatly marked. One very grave defect in land-culture, both in market and farm-field culture, but especially so in the former case, is the crowding of an excess of fibre-manure into soil that is very shallow-cultivated. Were the subsoil broken up, and one-half the manure-dressing buried, the average crop-production would be immediately and for a long time doubled. Manure-merchants are thinking only of disposing of their wares, and cultivation is to them of trifling moment. Practically, the cultivator who deepens the root-area of his ground

by trenching or subsoiling, at once doubles the crop-area of his land, without adding to it one single shilling for rent or for manures. I have a lively recollection of the manure-trials conducted during a dry season at Reading a year or two since, and the singularly inconsequential results that followed. The first thing to do in employing manures, artificial or otherwise, is to ascertain by analysis their fertilising strength. Then it is important to know something of the actual condition of the ground. At Reading, for instance, we saw soil unmanured for two years giving as good results as came from plots manured for two years. No wonder if all who came to learn went home as wise as they were when they set out. *A. D.*

THE SHADING, VENTILATING, WARMING, AND LIGHTING OF VINERIES CONTAINING MUSCAT VINES.

—Mr. Smith, gardener at Harewood House, Colin Deep Lane, Hendon, has some sensible, if somewhat startling, remarks on this important subject in the *Gardeners' Chronicle* for September 25, p. 219. The most sensible part of his note is his assurance that it is essential to good flavour that the vinery should be carefully ventilated at this season; for the Grapes should be ripe at the end of the month unless wanted for table at a very late date. This is always admitted. The vinery should have air admitted when its temperature rises to 70°, as a degree higher than that might cause scorching of the foliage. If this errs at all, it is on the side being too cool, a safer thing than the excessively high degree of warmth afforded Muscats by some gardeners. But the shading with a double fish-net over the glass is the most startling receipt for the making of perfect Muscat Grapes that I have come across. It may indeed at times prevent scorching of the foliage; although, due care exercised in ventilating would remove all danger from this source, and it is the only thing necessary under our rather watery sunshine. The removing of the fruiting laterals of Grapes 4 or 6 inches from the glass is also a much safer caution to take care against the scorching of the leaves or the fruit than the use of shading material. The fullest exposure of the Vines to sunlight is another antidote to the scorching of Muscats and other Vines; plenty of light and air combined rendering a Vine less liable to scorching of the leaves than a moist, close method of culture. I entirely agree with Mr. Smith as to the need of early maturity for the production of high quality and sound and long keeping. Other conditions being favourable, a rise of 5° or more to hasten maturity need not injure the fruit when it is approaching perfect ripeness; and with greater warmth in a vinery in moderation, the more aerial movement is caused, and that, too, without, draught. *D. T. F.*

BOILING PEAS (BLUE BOILERS).—Few perhaps are aware that Peas for boiling in a dry state are grown most extensively. Thousands of quarters are harvested and sent to the manufacturing districts—to Lancashire and Yorkshire especially, for boiling. Throughout Lincolnshire especially, on the soils suitable for the production of Peas, very large breadths of certain blue varieties are sown for this purpose; indeed, it is an important and remunerative crop for the farmer to cultivate. The leading varieties grown for this purpose are Harrison's Glory and Bedman's Imperial, the latter an old variety which has been in cultivation for nearly or quite sixty years. These varieties are harvested when ripe in the usual way, thrashed out, and sold to the merchants, who have them handpicked, and then they are marketed, finding a ready sale in the midlands and northern counties, and they may be regarded as a staple article of food in the manufacturing districts. Those who retail these Peas boil them, and then take their position in the market, or some open place about 8 o'clock in the evening, a bell is rung, the women crowd round with basins purchasing them while hot for the family supper. Probably there are many persons with scanty means who are unaware what a valuable and satisfying, as well as nourishing article of food boiled Peas are. They are best soaked for twenty-four hours in water, and then they boil perfectly, and come to the table soft and edible, finely flavoured, and by many as well esteemed as fresh-gathered Peas. It is doubtful if the vegetarian restaurants supply Peas in this way; in our ordinary eating-houses and restaurants they appear to be unknown. Good samples of boiling Peas will sell at from 60s. to 80s. per quarter; the price depends upon the quality. It may be added, in reference to soaking the Peas in water before boiling, that the water should be cold, and sometimes so much of the water do the Peas absorb, that it is necessary to supply more. It is usual to boil in

the second water when this is the case; also to allow the Peas to gently simmer for two-and-a-half hours, and not boil too rapidly. All dry Peas will not boil well, but remain hard. This is the reason that the two varieties named above are so popular for the purpose. Those which boil well of the old stocks left on hand are available for split Peas; those which resist the efforts of the cook to render soft and palatable, are useful for cattle-food. *R. D.*

CHRYSANTHEMUM - FUNGUS.—I enclose some *Chrysanthemum* leaves infested with the fungus your correspondent "M. C. C." so accurately described on p. 256. I first noticed the disease early this year on some young plants of an American variety received from a *Chrysanthemum* specialist; and being suspicious it might develop seriously, I had all leaves carefully removed that were affected. It continued to show itself throughout the season, but there was no serious spread until the months of August and September, when it appeared on almost every plant in a collection of some 400, within a week of showing active signs of spreading. Every means were taken to combat it by spraying and syringing with fungicide, including Paris Green and other copper solutions, but with little or no effect, and so far I have been unable to arrest its progress. Some varieties suffer much more severely than others, notably Modesta, New York, Pride of Exmouth, and others of soft growth. Whether this fungus has been imported with American varieties or not it would be interesting to learn, as it seems singular there should be this sudden outbreak in so many different parts of the country in one season. Perhaps some of our *Chrysanthemum* nurserymen could enlighten us. *F. H.*

BORDEAUX MIXTURE AND THE POTATO DISEASE.—Of the English or Scotch peasants, and even myriads of gardeners and farmers how few have employed the copper mixture as a factor in Potato culture, how few indeed believe in it! But in all localities where the Potato disease largely prevails, and of course specially so in a humid country like Ireland, if any efforts are to be made in the use of the Bordeaux Mixture, the operating force must be the local authority. I startled some Gloucestershire farmers some time since by suggesting that to properly grapple with the Winter moth pest, local authorities should not only have power to enforce the use of proper remedies, but should possess for local use and hire all the needful appliances. It would be only in that way that any great outbreak of the moth-pest amongst the fruit orchards could be stayed and overcome. We want exactly the same sort of thing in relation to the Potato disease. How few can purchase the needful tubs, ingredients, or sprayers. It is all very well to rail at the idleness of the peasant, but let the railers put themselves in his place. Now, were the needful requirements locally furnished, and powers to enforce their use in each authorities' district given, how much might be accomplished all the country over in arresting the spread of the fungus. The small breadths in gardens and allotments could be done by an expert rapidly; and in Ireland especially, the cost, necessarily a trifling one to the peasant, might be repaid several times over in the saving of the tuber crop. In matters of example, local authorities are the most suited to lead the way. *A. D.* [The Jensen system of high moulding is better for the labourer than the copper treatment.—*Ed.*]

SHRIVELLING OF VENN'S BLACK MUSCAT GRAPES.—In this interesting case, referred to in last week's *Gardeners' Chronicle*, p. 274, no certain cause of shrivelling is indicated. "Vine" is, however, probably on the right tack when looking for it in the dryness at the roots, either early in the season (March, as he indicates), or during the summer, or towards the autumn or finishing of the Grapes. Probably very few Vine-growers would approve of watering the borders at intervals of three weeks; and the editorial suspicion that these might have been chiefly or wholly absorbed by the surface-soil, without reaching the main roots, is possibly correct, and may have been contributory to the shrivelling. But as you truly add, more facts are needed as to the character and depth of soil, drainage, fall, width, age of borders, whether outside or in, or both, as is more frequently the case before the causes of the conversion of the Grapes into raisins, during their finishing stages, are likely to be unravelled. While waiting for such particulars, growers could hardly be more profitably employed than in pondering the first portion of the editorial sentence on this interesting case, which seems as follows:—"Unless the border was thoroughly saturated, which could only be ascertained by excavating a small hole here and

there down to the drainage," &c. Now, until quite recently, this was the only means open to fruit-growers for testing the growing needs and physical conditions of their Vine or other fruit borders. It was so slow, cumbersome, risky, as to be far oftener honoured in the breach than the observance. Hence the second and other remedies suggested of uncovering the outlets in the drains themselves, &c. But now the mellow experience of a famous Grape-grower has invented a simple instrument, which I have lately seen at work on some of our best Vine-borders, which reduces their testing and trying to something like the simplicity and despatch of the tasting of cheese. In fact it is founded on similar principles. A half circular tube of steel is thrust into the cheese or border to any desired depth, and turned round and withdrawn with a section of the contents fully exposed for tasting, testing, and thorough complete examination. The soil may then be returned to the spot whence it was withdrawn, with the utmost despatch, and a minimum of disturbance to roots or border. As the result of such examination I found a heavy crop of late Grapes being slowly flooded with running water in October. Also that few of our first-class Grape-growers seem to believe in dryness at the roots at the finish as a factor in the development of the highest flavour, or the laying on of the densest bloom. The inventor of this new test for Vines or other fruit-tree borders, or other soils, is the well-known Scottish Grape-grower, Mr. Alexander Kirk, Norwood, Alloa, where I had the pleasure of making its acquaintance. Mr. Kirk has provisionally patented it, as it is sure to have a great future in horticulture. It is simple and strong, made of steel, has a strong cross-bar as a handle, weighs about 12 lb., and is 4 feet in length. In porous borders it can be pushed in by the force of both hands; in stiffer soils, a wooden mallet sends it down to the bottom of the border with a few blows. A sharp wrench or turn of the cross-bar in an upward direction, and the instrument, with its unbroken segment of soil, is under inspection. The inventor adds: the temperature of the border can also be ascertained by placing a ground thermometer in the sheath of the instrument. This is especially important in early forcing. In the circular which I enclose, by which you will see that this instrument is only a guinea complete, the inventor, who writes with special authority on such subjects, truly says, "That one of the grand secrets in plant and Grape-growing is to know when to give water, and when to withhold it. As a rule Vine and Peach-borders are too often dry at the bottom when least expected; this will cause Grape-shanking and Peach-dropping." Never give a Vine-border a heavy drenching of water until you have tested the soil with this instrument. Over-watering or under-watering will lead to bad results. The system of watering Vine-borders every ten or twelve days is groping in the dark, and cannot be too strongly condemned. I may add, that other famous Grape-growers, whom I have recently seen at home, highly approve of this handy and efficient border-tester. D. T. Fish, 12, Pettes Row, Edinburgh.

SOME NEW FUCHSIAS.—That veteran Fuchsia grower and raiser, Mr. James Lye, of Market Lavingson, Wilt, although he has left his half-century home at Clyffe Hall, and has taken up his residence at Easterton, near the same town, is still on the war-path in his old operations. He exhibited splendid plants at Bath recently, and has just sent me, to show that he is still raising new ones, bunches of half-a-dozen that exhibit very superior form, and must be exceedingly floriferous. Mr. Lye has never worked to obtain the huge flowers continental growers have sent us—varieties that would be useless for exhibition or travelling. He has aimed to secure stout sturdy growth, short jointed, and carrying in profusion bloom that is very massive, and hangs well. Capability for good travelling is a special feature of Mr. Lye's seedlings, and it is indeed a matter of no small importance when plants have to be carried by road or rail some 20 or 50 miles. For all ordinary bedding purposes, these sturdy varieties are the very best also. Clipper is a rich red, sepals well reflexed, corolla deep claret-red. Snowdrop has large globular buds that open fully, and expose a long petticoat of white petals, barrel-shaped, and slightly streaked red; Mrs. Hobhouse is a handsome white, having a long tube and broad sepals, with rosy-red corolla; W. H. Mould, white tube and sepals, which are long and well reflexed, corolla cerise-red; Eclipse, also white, but more massive, with rosy-carmine corolla; and, finest of all perhaps, Jubilee, with massive tube and wax-white sepals, with broad, rosy-red corolla. A. D.

YEW.—I have been much interested in the leading article on Yews which appeared in a recent issue of the *Gardeners' Chronicle*. I have here forty different sorts planted side by side. Among them are several seedlings, both green and variegated, between the common and Irish Yew. One variegated variety is more vigorous than the common Yew, and it will make a very large tree. Another variety is a great improvement on the present variegated Irish, growing broader and of beautiful form. William Paul, Waltham Cross.

NEW INVENTION.

A CONTRIVANCE FOR ELEVATING ORCHID-POTS.

AN exceedingly simple stand is sent us by Mr. Wm. Murray, the skilful Orchid-grower to Norman Cookson, Esq., Oakwood, Wylam-on-Tyne. It consists of two metal rings of different sizes, and united by three thin rods or pillars placed triangularly. The smaller ring, of course, is placed at the top, and the stand has therefore much the same shape as an inverted pot, the base being largest. It differs, however, very widely from the pot, for it affords no check to the circulation of air among and under the plants. In a pot the air there accumulated must become impure from comparative stagnation, and the present stand is recommended as preventing this. A plant upon such a stand would be practically suspended. Moreover, these stands are likely to remain clean a long time, and they will not break. Of course, they can be had in any size or height. As a plant-elevator, we consider it a capital one, and theoretically it should possess decided advantages over pots, although the latter have been used so long, and given such comparative satisfaction.

Obituary.

E. J. BAILLIE.—It is with great regret that we have to announce the death of Mr. E. J. Baillie, so long connected with the firm of Dicksons, of Chester. Mr. Baillie died on Monday last. In our next issue we hope to publish an account of his career, which was one not of limited, but also of general usefulness.

MR. ISAAC DAVIES.—The death of Mr. Isaac Davies, senior partner in the firm of Davies & Son, nurserymen, Brook Lane, Ormskirk, took place on Sunday, the 10th inst., at the ripe age of eighty-five years. The deceased belonged to the old school of nurserymen, and carried on a very lucrative business for many years at the above place. He was the raiser of many good Azaleas and Rhododendrons, Pelargoniums, Calceolarias, &c. Azaleas Daviei and A. Avalanche were of his production, as were Rhododendrons precox, multiflorum, elegantissimum, and the beautiful and fragrant Countess of Derby, Countess of Sefton, Lady Skelmersdale, Duchess of Sutherland, Miss Davies, Mrs. James Shawe, and many hardy varieties, such as R. Lothair, Monarch, Resplendent, and La Brillante. He thoroughly believed in doing things well, and was a good all-round plantsman. A. O.

REV. C. S. P. PARISH.—The death occurred on Monday of the Rev. Charles Samuel Pollock Parish, who passed away in his sleep at his residence, Roughmoor, Somerset, at the age of seventy-five years. Deceased, who was a fine scholar, and was very much interested in botany and the doings of the Somerset Archaeological Society, took his degree of B.A., at St. Edmund's Hall, Oxford, in 1841. In 1852 he became Indian chaplain at Moulmein, Burmah, and held that position until 1876. Two years later he retired, and held no further permanent duty. Mr. Parish was an ardent Orchidist, making large collections in Burmah, and was the discoverer of many new species, most of which were described in these columns by the late Professor Reichenbach. A Vanda, a Cyrtopodium, and numerous other Orchids bear his name.

MRS. THISELTON-DYER.—On the 13th inst., at 118, King Henry's Road, N.W., after a long illness, Catherine Jane Thiselton-Dyer, widow of William George Thiselton-Dyer, M.D., of 7, Berkeley St., W.

SOCIETIES.

ROYAL HORTICULTURAL. SECOND DAY'S CONFERENCE.

PROGRESS IN VEGETABLE CULTIVATION DURING QUEEN VICTORIA'S REIGN.

(Continued from p. 277.)

OCTOBER 8.—

ASPARAGUS.

Until quite recently, English gardeners and their employers appeared to be quite satisfied with the kinds grown when the Queen came to the throne, such as Giant and Battersea; but the greater facilities for reaching the Continent have resulted in the desire to cultivate the sorts which produce the massive sticks so well grown in France. The most popular strain of the latter is the best selection of Argenteuil; and when the English cook has learned to imitate more closely the methods of the French chef, we shall doubtless find as delicate and delicious Asparagus in London restaurants as in those of Paris.

In like manner has the increased taste for Globe Artichokes been formed, a delicacy which was seldom grown fifty to sixty years ago.

The increased use also of Sugar Peas, Waxpod or Butter Beans, Celeriac, Chloory, Endive, Cardoons, Egg-plants, Silver or Seakale Beet, and other kindred subjects, may be traced to the same cause.

We do not appreciate all the ways of railway companies, but they have undoubtedly been the means of introducing us to some of the more delicate and delicious vegetables of the Continent.

BEET.

Salads are much more popular now than sixty years ago, and as Beet perhaps comes next in importance to the Cucumber and Lettuce, the natural result has been a marked improvement in the varieties grown. In the early days of the Queen's reign, "Dwarf Red," "Large Red," and "Turnip-rooted," were the sorts in use. Seeing how difficult it is to obtain seed which will produce absolutely uniform results in colour of leaf, &c., it was a happy idea on the part of the seed-seller of those days to protect himself by labelling the packets with such comprehensive names as "Large Red," "Dwarf Red," and "Turnip-rooted." It is quite certain that even now the former description would be very applicable to strains frequently seen growing. In 1841, "Whyte's Black" was introduced, a variety almost black in the flesh, but inclined to be coarse in texture, as well as strong in growth, and with considerable variation in the colour of leaf. Notwithstanding these faults, it is still to be found in nearly all seed-lists, and presumably, therefore, has its admirers. Of late years a large number of improved types of this class have been seen, and those who fancy Beets with flesh almost black have no lack of choice.

Later introductions which remain popular were "Nutting's Dwarf," "Pine-Apple," and "Dell's Black-leaved." Of the first and last various selections have been made, resulting in uniform and excellent types.

Within recent years "Cheltenham Green-top" has also come to the front, although I understand it has long been grown in the neighbourhood from which it takes its name. It is an excellent Beet, although disliked by some on account of the colour of the leaves. The "Turnip-rooted," so useful for shallow soils, has undergone great improvement, the flat type, called Egyptian, being almost superseded in English gardens by the introduction in 1891 of our Globe, which is as perfect in form and clean in growth as a Snowball Turnip. Many types of Globe Beet have also been introduced from America, but generally speaking, the colour of the flesh is not up to the English standard.

A strange development in the leaves of the Beet has lately been observed, and we may soon see in our flower gardens a variety which produces a beautifully variegated foliage in addition to a very fine well-flavoured root. A white Beet called Bassano was also grown in the thirties, but it never became very popular. In recent years efforts have been made to popularise a yellow-fleshed kind, but although I can vouch for the excellent flavour of this Beet, the general public do not appreciate it.

THE BRASSICAS.—CABBAGE.

First and foremost in point of general utility comes the Cabbage. Although our forefathers had not so long a list of names to select from as gardeners now have, there were several good Cabbages in 1837. Chief among these were Early Battersea, Early York, Large York, Emperor, Sugar-loaf, &c., names which still retain a place in all seed lists, and are certainly valuable for spring sowing. It is reasonable to suppose that the crops of those days suffered from "bolters," and with none but these and similar sorts to grow the probability is that an even bed of Spring Cabbage would be the exception, as these sorts are peculiarly liable to bolt. Of late years much has been done to avoid this tendency, and we now have such Cabbages as Ellam's Early, Early Offenham, Imperial, and our own Flower of Spring and Early April, which when obtained true to name may be relied upon in any season to form solid hearts without bolting.

The improvement in the Cabbage has been entirely due to selection. The advent of the Nonpareil was a distinct gain to horticulture. Amongst others Shaw of Newbury, did much to make this Cabbage popular, and as it is one of the best for spring sowing, it will be long before it ceases to be grown. Enfield Market is popular where a large growing

kind is required. Almost every market-gardening district has its own particular selection, as seen in The Raleigh, Higham, Evesham, East Ham, and Fulham varieties.

Rapid strides have been made in the improvement of early Cabbages for summer use, and although many of the earliest are of Continental origin, we on this side can claim no inconsiderable amount of credit on account of the careful selection given to them. Earliest of All, Express, and their kindred types of Cabbages which we could not now well do without, but on account of their tendency to bolt they must give place for August sowing to the sorts previously named.

The Hardy Green Colewort was introduced in 1852, and a selection from it, Rosette Colewort, appeared a few years later. These are very important crops for consumption towards the end of the year, and are delicious in flavour.

Red Cabbages have been so far improved that instead of relying on an August sowing for heads to use the following summer and autumn they can now be obtained in the same year by sowing in spring.

Savoy Cabbages, on account of the limited period in which they are required for use, have not had so much attention devoted to them, although it is now possible by the use of recently introduced early and later kinds to extend the supply from August to April if required.

BRUSSELS SPROUTS

amongst Brassicas stand second only to the Cabbage, Broccoli and Cauliflower in importance. This plant was well known in 1837, but since that time wonders have been accomplished in its improvement by means of selection, and we now have dwarf, medium, and tall varieties of great excellence. Strymger's Giant, Dalkoth, and Reading Exhibition were among the earlier improvements, while the Dalmeny and Albert Sprouts first offered about 1858-9, had but a short-lived reputation.

A dwarf type originating on the Continent, and covered with close firm buttons, has of late years given grand results, the best known strain being the Dwarf Gem. As is well known the sporting tendency of the Brassicas is responsible for some very peculiar forms, and it is I think, not at all unlikely that a Brussels Sprout with red buttons may eventually have a place amongst our favourite vegetables.

BROCCOLI

were represented in the earlier days by the Cape, Grange's Autumn, Portsmouth, Sulphur, Dwarf Russian, Purple Sprouting, and Knight's Protecting. In 1843, that popular sort, Snow's Winter White, was first offered, and although various and inferior strains have been offered under this name, it is safe to say that in many cases the seed now sold is altogether superior to the original type. The following year Walcheren, which perhaps should be classed amongst the Cauliflowers, was brought to notice, and has done good service. After this came Adams' Early, Wilcox's Late White, Dilcock's Bride, and White Sprouting. In later years, Broccoli with heads of closer and whiter texture have appeared, including Leamington (still one of the best), Perfection, and Late Queen. Great improvements have been made in Purple Sprouting Broccoli by selection, and it is now possible to grow three distinct types, the earliest of which is available for use at Christmas, the ordinary type following, and lastly a late selection of more compact growth and better coloured sprouts. The hardness of these strains is an important feature, and their popularity must continue.

In the late Broccoli it has been difficult to retain lateness without in some degree sacrificing colour and quality, but I am pleased to note that a late Broccoli, which continues good in quality longer than any variety with which I am acquainted, and with heads which are in every way equal to an autumn Cauliflower, is already in existence, and will certainly become deservedly popular. By these late, as well as the extra early selections, there is now no difficulty in having a succession of good Broccoli and Cauliflower throughout the year.

CAULIFLOWERS

are scarcely to be surpassed for delicacy of flavour when properly cooked. Three types were grown in 1837, the Early, Late, and Asiatic. These were followed by the Stadtholder and Walcheren, Snowball, Erfurt, and Autumn Giant. As Cauliflower seed can seldom be successfully grown in England, we are, of course, indebted chiefly to our Dutch, German, and Italian specialists for most of the improvements made; and with the finest types of the Dwarf Erfurt section, such as Snowball and First Crop at one end, and the early and late selections of the Italian Giant varieties at the other, we can extend the supply over a very much longer period than was possible sixty years ago. A head of Cauliflower 36 to 38 inches in circumference of perfect quality was a thing unheard of in 1837, but it is by no means uncommon to-day.

KALES

The great diversity in colour and form of this section of the Brassicas at the present day would surprise any gardener who knew only the few sorts existing at the commencement of the Victorian era. The hardness of this useful vegetable has always been its most important feature, and it is to be hoped that the newer selections will retain this essential characteristic.

During the fifties Mr. Turner introduced the hardy and most useful Cottager's Kale, and it appears to increase in favour. Mention must also be made of the Variegated Kale, a highly ornamental plant, as well as useful for cooking purposes. In mid-winter the charming colours of the leaves render them invaluable for decorative purposes.

THE CELERIES OF 1837

were the Italian, Red and White Solid, and Turnip-rooted, and although at this date there are many superior sorts, Celeries vary so little in character that there is less scope for great improvement than in many other garden vegetables. Much, however, has been done in improving the solidity and flavour, and amongst the Reds may be noted Clayworth Prize, A1, Standard Bearer, Sulham Prize, and Leicester Red, with Solid White and Wright's Grove White as the best of the white section. Probably the most distinct variety of English origin is White Gem, a small early sort of great value.

Attempts have been made to popularise the continental self-blanching sorts, but although they may be useful for soups, they are practically of no value where tender fine-flavoured Celery is prized, for except in appearance they differ but little from unblanched English Celeries.

CARROT

In Carrots the progress made has been as great as in other vegetables during the period under review. Although there were several varieties grown in the early years of the Queen's reign, they were either very long, such as Altrincham and Surrey, or of the horn section. Improvements on some of these quickly appeared, James' Scarlet Intermediate at once meeting with approval, and for market purposes this will doubtless long continue to be grown. Our French neighbours are adepts at the improvement of the Carrot, and the English trade is indebted to them in this respect to a larger extent perhaps than for any other vegetable. The French Forcing Horn and Nantes have met with warm approval, the finest types of the latter being particularly free from the objectionable yellow core existing in most sorts. It is only necessary to refer to the magnificent specimens of New Intermediate and Early Gem, and similar varieties which are so frequently seen on the exhibition table for evidence of the great improvement which has been made in this popular vegetable.

THE CUCUMBER

was represented by numerous sorts at the time of the accession of the Queen. Chief among them being Early Frame and White and Black Spine, besides the so-called Long Prickly and Short Prickly Ridge Cucumbers. Snow, Cuthill, Mills, and Constantine were among the earliest improvers of this popular esculent, and by 1842 many varieties were available.

Kelway's Victory and Phenomenon, Sion House, and Victory of Bath appeared during the fifties, and a few years later Berkshire Champion and Manchester Prize. It was then that Thomas Lockie took the Cucumber in hand, and Blue Gown (and its sport Tender-and-True), Royal Windsor, and the deservedly popular Lockie's Perfection were the leading varieties raised by him. Meanwhile other sorts, including Telegraph and Cardiff Castle, obtained a leading place, and it will be a long time before Telegraph is superseded for general cultivation.

I have not enquired from the Messrs. Rochford how many years the Rochford Cucumber has been in their family, but it is probably more sought after by growers for market than any other variety. In recent years the palm for raising improved varieties must certainly be given to Mr. Mortimer, whose wonderful exhibits at the Drill Hall and elsewhere have been greatly admired. Sutton's A1, Peerless, Progress, and Matchless are results of his painstaking work.

Notwithstanding the almost endless varieties now procurable, it is generally admitted that none of them supply the ideal type required for cultivation on a large scale. For productiveness no sort equals the best strain of Telegraph, but the somewhat pale colour, especially when the plants are bearing a heavy crop, lessens its value for market purposes; and if the council of the Royal Horticultural Society should see their way to undertake a series of trials at Chiswick, I would gladly offer a prize of £5 5s. for the seedling Cucumber, raised since 1896, which shall combine the productiveness and excellent form of Telegraph, with the dark colour of Rochford's Cucumber.

THE LEEK

In 1837 was represented in this country by the common and Flag types, although it is on record that in the previous year four Scotch Leeks were produced in Edinburgh with a circumference of 9 inches or more. A Scotch gardener now living informs me that although he came to England in 1854, it was several years before he saw Leeks grown here. The Musselburgh was one of the first improved forms, followed by Aytton Castle and Henry's Prize. The greatest triumph, however, is found in the Lyon, and the better selections of this good variety, such as Prizetaker, appear to present as perfect a form of Leek as it is possible to obtain or desire.

In this connection may be mentioned the excellent work done by the Messrs. Dobbie, who have introduced one or two very fine selections of Leek as well as of several other vegetables.

LETTUCE

The number of varieties, both Cos and Cabbage, has wonderfully increased during the past twenty years, and they embrace many types and shades of colour.

In 1837 several of the leading varieties of the present day were in use, including, amongst the Cabbage varieties, Brown Dutch, Brown and White Silesian, Drumhead, Grand Admiral, Hummersmith, and one or two others; and in the Cos, White-seeded and Black-seeded Bath, Florence, Green, White, and Spotted.

By 1842 Paris White and Green were announced, and the various selections of this type are among the best Cos Let-

tuces at the present time. More recently a very large amount of great excellence, named by my house Mammoth, appeared, and is very popular. White Heart, intermediate colour between Paris White and Green, deserves a popular introduction of recent years. With regard to Lettuce, the number of varieties now available is enormous. All the Year-Round was amongst the first introductions, and so good is it that it has been honoured several distinctive names. Wheeler's Tom Thumb, Perfect Gem, Standwell Green, and others are excellent largely in use; while more recently, Commodore Favourite, and Daniel's Continuity are improved to a great merit, the two latter standing longer than others without running to seed.

Recently my house has introduced the Intermix variety resulting from a cross between the Cabbage Lettuce, which is highly prized by many.

THE MELON

has advanced during the past sixty years by leaps and bounds. Every year witnesses the advent of new varieties, and the Fruit Committee of the Royal Horticultural Society can testify to the constant succession of aspirant honours.

In 1837, gardeners depended upon the Cantaloup, fleshed, Green-fleshed, Lord Sondes, and Queen Pocket. In 1842, Windsor Prize Green, and one or two scarlet-fleshed kinds, were distributed. Ten years later, Beechwood, Bromham Hall, Victory of Bath, and standard varieties were grown, followed at short intervals by Scarlet Gem, Blenheim Orange, Hybrid Cashmere, and Green, Hero of Lockinge, the latter still retaining its place as the best Melon for frames. So easy is the task that it has acquired the reputation of being essentially an amateur's Melon.

In connection with improvement in Melons, much work has been done by Mr. Owen Thomas of the Gardens, Mr. Wythes of Sion House, Mr. Chas. Ross, and many others. In 1894 we had the pleasure of introducing a handsome white-fleshed variety, raised by Mr. T. named Royal Favourite, and other noteworthy Melons also emanated from the Frogmore Gardens.

ONIONS

were represented sixty years ago by Blood Red, D. Silver-skinned Globe, James Keeping, Lisbon, White Brown Spanish, Portugal, and some of the Tripoli varieties. While most of the types have undergone more or less improvement, special attention has been given to the class. The Reading was a valuable selection, and followed by Improved Banbury, named after a town which has long been popular for its Onions. The late Mr. J. of that place introduced many fine types, such as R. Park, The Wroxton, Anglo-Spanish, and others. B. Cross, a comparatively recent introduction of fine quality also hailed from the same town.

The justly celebrated Allis Craig (with Cranston's sior, a very similar Onion), has caused quite a revolution in this vegetable. One celebrated grower last season exhibited twelve specimens weighing no less than 37½ lb., an enormous weight for this country, which would have startled growers of the olden days who had to be content with specimens weighing only a few ounces each.

Until quite recently it had not been possible to obtain the fine Spanish Onions of the grocers' shops, and all specimens grown in this country are not often so large as imported bulbs, some very fine Onions can be grown in the seed in heat in January and transplanting in March.

THE PARSNIP

has certainly been much improved since the Guernsey Hollow Crown were the only available sorts, although very great increase in the number of varieties can be seen.

As late as 1852 the only one quoted in a leading work was Hollow Crown. The Student, obtained by Professor Buckman, by continual selection from the Parsnip, and distributed by my house first in 1860, regarded as a popular variety; and has been since successful at shows. Quality in a Parsnip is almost a matter of selection, and in that way the fine types cultivated have been obtained. Carter's Maltese is a distinct advance, and is still widely grown. Quite recently at the Reading Show, where the general opinion was extensive and fine a collection of vegetables was never staged in competition, some of the collections contained remarkable specimens of a new variety called Tender-an. This is certainly distinct from other kinds, and its quality which has not hitherto been reached in this vegetable.

SPINACH

No great advance was made in this vegetable until years ago, when the Victoria and other similar strains were introduced. It is true that many varieties bearing mental names have been grown, some standing rather than others before running to seed, but the difference only slight. With the advent of the Victoria, however, the duration of the crop was greatly prolonged, and at present this variety has been surpassed, and we now have both in the round and prickly-seeded sections, the Spinach which remain good weeks after others have gone to seed.

Time will not permit of my referring to Parsley, B. Vegetable-Marrow, and some other vegetables, and pass on to

THE TOMATO

which has increased in popularity to a greater extent more rapidly than any other vegetable referred to in paper.

A proof that it was not much cultivated in the early years of Her Majesty's reign is shown by the fact that in a wholesale list published in 1852 the only Tomato mentioned is the common Red. It is within the last quarter of a century that such an enormous impetus has been given to the growth of Tomatoes, in consequence of the more cultivated taste of the masses of the people, and it is now found in almost every garden from the cottager's upwards. The Queen's gardener, Mr. Thomas, has identified himself with its improvement, and Frugmore Prolific is one of the best sorts grown at the present day.

The introduction of the Perfection type was the prelude to that of many others, and now the number is legion. New selections are plentiful enough, as our own trials of over 200 lots this year go to show. The question which is the best Tomato admits of a multiplicity of varying answers.

To mention in detail anything like the whole of the varieties which deserve notice would take up too much time, but for earliest outdoor use, Conqueror, Earliest of All, and Early Ruby, are popular kinds. Fine shapely fruit, and plenty of them, are produced by Isid Gem, Eclipse, Best of All, Duke of York, and Ham Green Favourite; and in yellow varieties, Golden Nugget as a small-fruited kind, and Golden Queen may be relied on to ripen early and produce good crops.

Strange developments, in which the fruit (seemingly) partakes of the character of the Peach, are observed in certain kinds, and the crossing of the Peach-Tomato with Perfection has resulted in some charming types, amongst the best of which is one introduced by my house last year under the name of Peach-blow. Certainly no gardener in 1837 ever dreamt of the fruits now commonly grown.

With white, yellow, pink, ruby, and scarlet kinds, not to mention the varying sizes and shapes, there is a wide choice for the most fastidious, both as regards external appearance and flavour.

GARDEN TURNIP.

A brief reference must be made to the garden Turnip. In the early days as many yellow as white varieties were offered, although the demand for the former has certainly not increased in proportion to that for the white-fleshed kinds.

Amongst the many improvements may be noticed Veitch's Red Globe, Snowball, Dobbie's Model, and Go den Ball, while the Red and White Millans are varieties which arrive at maturity quicker than any other Turnip. These should not be confused with their prototypes the Red and White Strap-leaved, which have almost had their day.

Several important sorts have been imported from the Continent in addition to the Millans, but much selection and improvement has been necessary to make them worthy of a place in English gardens.

POTATOES.

It will obviously be impossible for me, at the close of this lengthy paper, to attempt to describe at all adequately the improvements effected in the Potato during Her Majesty's reign, and as I have already in my paper on "Potatoes," published in vol. xix., No. 3, of the *Journal of the Royal Horticultural Society*, dealt somewhat fully with this subject, I must content myself now with the fewest possible remarks. As long ago as 1836, Messrs. Peter Lawson & Sons published descriptive list of 146 varieties, and amongst some 45 of the principal of these I only find one which is still cultivated, viz., the Early Ashleaf. There are, besides these, some familiar names, such as Early Shaw and Dons, but the remainder must have passed out of cultivation at least twenty-five years ago.

In 1852, the old Walnut-leaf Kidney, Early Oxford, Forty-fold, and York Regent were grown—all sorts of royal merit in their day, but now seldom met with. That excellent Potato, Paterson's Victoria, was widely cultivated up till 1850, but it would be difficult now to find an acre of this variety true to name. The fact that almost all these have disappeared from sight does not of itself necessarily prove that they were worthless, or even inferior to others grown at the present time; for it is generally admitted that the majority of Potatoes will not maintain their full vigour of growth and constitution beyond a certain time, the limit varying with each sort. This is not to be wondered at when we remember that each year's growth is but the prolongation of the life of the plant, which apparently had completed its work when the haulm died the preceding autumn.

At the same time, I have no doubt whatever, that even if we could reproduce such favourite varieties as the Regent, Paterson's Victoria, &c., in all their former excellence, and plant them by the side of the best Potatoes of to-day, we should find very great progress had been made, not merely in productiveness and power of withstanding disease, but also in favour—a point in which the older sorts are often supposed to have excelled. Besides this, we have in Ring-leader, Al, Early Puritan, &c., first-early sorts which are ready for use long before the so-called early Potatoes of twenty-five years ago, and also several second-earlies, such as Beauty of Hebron, Supreme, and Windsor Castle, which certainly were not equalled by any of the older varieties in their own section. Whether these will still retain their good qualities unimpaired twenty-five or fifty years hence, no one can say, though in all probability, as they themselves are instances of the survival of the fittest, in so far that they were chosen from thousands of less promising seedlings—several of them will doubtless greatly exceed the limit of age reached by older sorts.

In the late and maincrop section nothing has yet approached the Magnum Bonum in popularity, and it is certainly at least as good now as when introduced by my house twenty-one years ago. There are many other very similar varieties, but on the onset scrutiny I have failed to

detect any point in which they differ from the Magnum Bonum, and I have generally found when any difference has been suggested that the sorts in question were not grown alongside under the same conditions, or else that the seed had been obtained from different sources, a change of seed often producing a marked contrast in two rows of the same variety.

I must not leave the subject of Potatoes without mentioning such names as the late James Paterson, Mr. Robert Fenn, the late James Clark, and Mr. Archibald Fisdlay, all of whom have devoted many years, if not a lifetime, to the improvement of the "noble tuber," and to whom the whole horticultural fraternity and the community at large are so greatly indebted.

We have now passed in review all the leading kinds of vegetables, and I think, imperfect as this paper has been, we must all feel that the progress in vegetable cultivation during Her Majesty's reign has been little less than marvellous.

What the progress in the next fifty or sixty years may be no one can foretell; but on behalf of the seed trade I can only express the hope that it may be accompanied by a corresponding decline in the demand for older and inferior sorts, for the labour and anxiety of keeping the rapidly increasing number of varieties true to name is such as none but those acquainted with the details of seed growing can for a moment conceive.

The Discussion.

Mr. SHERWOOD said, having been in the wholesale seed-trade for forty years, he had followed the reading of the paper with great interest, and he bore testimony to the excellent manner in which Mr. Sutton had handled his subject. It might perhaps be asking Mr. Sutton to disclose trade secrets, but it would have been interesting to know the difference between the volume of trade done by Mr. Sutton's firm sixty years ago and the present time. For his own part, he thought they would all be astounded at the extraordinary demand that had sprung up for seeds during the past sixty years. That showed that the people not only wanted good vegetables, but plenty of them.

Mr. GEORGE BUNYARD said he could go "one better" than Mr. Sherwood, as he had been connected with the retail seed trade for forty-two years. For that reason he had followed the paper with more than ordinary interest, as he considered it astonishing that Mr. Sutton had been able to rake up all those old varieties which had long since been discarded. With regard to the garden Pea, Mr. Sutton said of the No Plus Ultra:—"Of its class, as a tall late Marrow-Pea, it is doubtful if any later introduction has ever shown, comparatively, a greater advance on previous kinds." He would say that in the Alfred the Great they had got all the qualities of the No Plus Ultra, with two or three more Peas in the pod and a more vigorous growth. Mr. Sutton had spoken of the difficulty of selection after Peas had been hybridised. He (Mr. Bunyard) knew that many good Peas had been utterly lost because people got tired of following up the selection. As to the old Peas, the increase in length of pod combined with shortness of haulm in the Woodford Marrow, had been marvellous. Great progress, indeed, had been made in the cultivation of all Peas, especially in preserving them during a hot dry summer. As to Runner Beans, a most remarkable thing had happened through hybridisation. In many cases if white seeds were sown, they reverted to their original form; and if red seeds were sown, they reverted to white, showing, he imagined, their hybrid character. With regard to Red Cabbage, very few people understand how excellent they are when cooked. It was a most delicious vegetable. True, its colour is somewhat objectionable, but anyone who had once tried it would be quite willing to overlook that point; it, of course, required a considerable amount of cooking. As a general rule, he would discountenance things being over-grown. The true test of a vegetable lay in the hands of the cook, and the smaller the vegetable the more likely it was to get cooked right through. In dealing with Tomatoes he noticed that Mr. Sutton had omitted the Conference Tomato, raised in connection with the Chiswick Conference some years back. He would like to bear testimony to the marvellous work done by Messrs. Sutton in regard to the Potato; but he could not help thinking that one great mistake had been made in sacrificing, in many cases, good flavour for a big crop. The Windsor Castle was one of Messrs. Sutton's triumphs, being one of the finest Potatoes ever grown. They owed a debt of gratitude to the Americans for introducing the Early Rose; but, taking things all round, he thought there was no Potato for field or garden culture equal to the Beauty of Hebron and the Puritan. Turning to another view of the question, Mr. Bunyard spoke of the false policy of buying cheap vegetables, characterising it as the greatest folly that could be perpetrated. He constantly saw vegetables advertised for sale which could not be grown for the money. Very few people had any idea of the great care and attention necessary in making a proper selection, not after the first or second attempt, but after a lapse of years. There was a tendency on the part of all vegetables to revert to some former type, and that required the greatest watching. He would, therefore, counsel people not to buy cheap seeds at any price. In conclusion, he said that Mr. Sutton had omitted to mention that great Potato-raiser, their friend Mr. Chas. Ross, of Welford Park Gardens.

Mr. Fyfe, of Messrs. Dobbie, said that many Peas were sent to Chiswick without any definition, and he would suggest that in the next year's publication of the Royal Horti-

cultural Society, people should be asked to send in proper descriptions, so that the Superintendent could have the older varieties grown side by side with the new. That would be only a fair test.

The chairman said there was one tendency at the present day which ought to be checked, and that was allowing old friends to appear under different names. At Chiswick they had some thirty varieties of Beet sent under different names, but upon examination there were found to be only five different sorts. As to new Melons, at least nineteen out of twenty that came before them were worse than their parents.

Mr. SUTTON, in reply, said much valuable work was done at Chiswick, but trials to be of value should be greatly extended. It would be better to have a Pea trial once every four or five years, and to do it exhaustively, than to but half do the work year by year. With regard to the Conference Tomato, it was one of the very finest types. As to the Potato, it was necessary to have a good crop, but they should also be determined to have the finest quality possible.

THIRD DAY'S CONFERENCE.

CULTIVATION FOR MARKET DURING HER MAJESTY'S REIGN.

Mr. Wm. Marshall, chairman of the Floral Committee of the Royal Horticultural Society, presided at the third day's Conference, when Mr. Asabeo, superintendent of Covent Garden Market, read a paper on the above subject. Mr. Asabeo said the Jubilee year had led to many interesting comparisons between the state of things existing at the present time and sixty years ago; and the annual show and gathering of the Royal Horticultural Society seemed a most suitable opportunity for reviewing the gardener's work during that period. He then traced the history of the growth of the garden from the commencement of history, remarking that originally they must suppose that every man was his own gardener. As the world became peopled, towns sprung into existence, and with these the market gardens, which supplied the wants of the community. Further great changes were brought about by the introduction of steam, which had altogether altered the conditions of life. The market gardener, driven from his suburban holdings at Battersea, Chelsea, Peckham, Deptford, and elsewhere, had to seek for fresh fields. The writer then gave an interesting description of the old-fashioned gardener, who religiously refused to depart from the hard and fast rules laid down by his forefathers, and proceeded to deal with the modern aspect of affairs. Dividing his paper into three main heads—vegetables, fruits, and flowers—he said, with regard to vegetables, that the cultural details of sixty years ago, with very few exceptions, remained the standard of the present high perfection. It was in the direction of earlier and improved varieties, and increase in quantities rather than in methods of culture, that comparisons would most tell. The cultivation of the Asparagus had shown the most remarkable progress. Many thousands of acres of this wholesome spring delicacy had been laid down. In the Worcester district alone there were 4000 acres, each acre producing 40,000 stalks, or 400 bundles.

CULINARY

exhibited another example of extended cultivation; and with regard to Peas, the most important summer vegetable, great strides had been made, especially in the Essex district, which had been fostered by the Great Eastern Railway.

ONIONS.

The introduction of the Spanish Onion had had a considerable effect on the improvement of varieties. In 1896 over 6,000,000 bushels of Onions were imported into this country, so that it could not be considered that we were overburdened with our home supply of Onions.

POTATOES.

The number of acres in cultivation in Great Britain in 1896 was 563,741, representing 3,562,235 tons. Lincoln was the largest Potato-growing county, possessing 57,638 acres, and growing 400,709 tons last year; Yorkshire had 51,495 acres, yielding 326,849 tons. On one day last season 1100 truck-loads of Potatoes arrived at the Great Northern dep't. There was still a very large importation of early Potatoes from the Canary Islands, Jersey, and Holland, valued at about £1,000,000.

BROCCOLI AND CAULIFLOWERS.

Coming to these valuable vegetables, a large quantity of Cauliflower was imported from Italy. Of the English varieties, Veitch's Autumn Giant was the best, and its popularity was largely due to its coming in at the beginning of autumn.

RHUBARB.

The present system of forcing was better than the old methods. In the season, 50 tons were brought into the London market in a day. In the United Kingdom there were 32,006,000 square feet of glass used for the forcing of 735 acres of Rhubarb, and the glasshouses, if they were 15 wide, and placed end on end, would reach 400 miles. After the Rhubarb had been pulled, the roots could be returned to the open ground for recuperation.

SPINACH.

is largely cultivated now; and as to Mushrooms, these required watchful supervision, with possibly much disappointment before success could be gained.

SALADS.

except for Mustard-and-Cress, we were almost entirely in the hands of the French producer for our early supply. He

looked forward, however, to a cheapening of glasshouse materials and frames to enable us to compete with the foreign and Channel Islands' producers.

FRUITS.

Fruits came next, and the speaker said that Kent deserved its title—"The Garden of England." With respect to Apples, the English producer was brought face to face with the American producer, and varieties should be grown for selling in the English market before the American fruit could arrive. The best market Apples were, Cox's Orange and Blenheim Orange Pippins, Lane's Prince Albert and Northern Greening. As to Pears, the best were Williams' Bon Chrétien, Pitmaston Duchess, Hessel, Louise Bonne, Catillac, and Winter Nellis. The best Plum was appropriately named Victoria, and Rivers' Early was a most valuable market variety. As to Dutch Plums, these were not in it as to quality with the English Plum, and the French Plum was over before ours was ready. Passing from Cherries, which were largely grown in Kent, the writer said that the Cornish and Southampton fields had done much to drive away the French Strawberry, and these were being assisted by the South Western Railway Company. British Queen Strawberry had no equal, but its cultivation was difficult. Sir Joseph Paxton was a good packer and a brisk flavoured variety, Sir Charles Napier was too soft, The President was a good old midsummer fruit, but the Royal Sovereign was the best of the newer varieties. Currants, both black and white, should be more largely grown. The Raspberry, a fruit that is much grown in the fields in Kent, and elsewhere, was a difficult crop to handle, and more Raspberries seemed to go into the jam factories than into the market.

FOREIGN IMPORTS.

Of small fruits which can be grown in this country enormous quantities were imported. In 1896, 6,177,193 bushels of Apples came from abroad, valued at £1,500,000. Of Pears there were imported 483,823 bushels, valued at £206,674; 560,246 bushels of Plums, valued at £241,782; 219,367 bushels of Cherries, valued at £105,246, or a total of 13,641,871 bushels of raw fruit, representing a value of £5,540,069, or an increase of £2,000,000 since 1871. He believed that if we could depend upon our climate, or had sufficient capital to enable us to wait on effort so as to extend our fruit culture, we should be amply rewarded; but the uncertainty of our climate was very much against extended fruit culture.

Mr. Asbee then displayed a box containing three dozen Californian Pears, and some Californian Plums, which he said were excellent in quality, but he doubted whether they could be put on the market at popular prices. He then advocated more effective methods of carrying on their work on a large scale, and alluded to the great efforts that had been made at Worthing, where there were now 650 glass-houses rated as agricultural land, and paying as such £8500 a year. If they took Covent Garden as a centre, a radius of fifteen miles would include most of the glass-houses in the country. The Lee Valley contained the most, and next came the Thames Valley, and Finchley, and then Bexley and Swanley in the more remote districts.

CUCUMBER.

The present system of cultivation has had the effect of driving the Dutch article from the market, and if people only understood the value of this as a vegetable as well as a salad, its consumption would be very much greater. Mr. Asbee next dealt with

FLOWERS.

He said nothing so much marked the advance of our working and middle classes in material progress, and in improved and refined taste, as their increased expenditure on flowers. In all conditions of life, and under all circumstances, this was seen, and flowers were now shedding their delicious perfume everywhere. Millions of potted flowers were sold annually; the trade in cut blooms was increasing enormously, and in this matter the English grower stood unrivalled. The trade in the Narcissus from the Scilly Isles had grown tremendously since 1885, and during the season it was not an uncommon thing to see 1600 boxes of these flowers arrive at the London market in one day. Cut flowers added to the pleasures of life, and their growers might on that account alone take a high standing among their fellow citizens.

In conclusion, Mr. Asbee said there was no doubt that the industry would increase, but here he would say a word of caution. The agricultural crisis through which we were passing had been due not only to the decrease in the values of produce brought about by foreign competition, but partly to fictitious value attached to farms through the competition of the retired mercantile man and other capitalists, who regarded farming as a healthy and a profitable investment for their capital. He saw signs of a similar feeling with reference to market-gardens and cultivation under glass; and although there was still room for further extension, he felt it his duty to advise a cautious policy and a due acquaintance with the details of the work before entering upon any rash outlay which might lead to loss and disappointment.

The Discussion.

Mr. Roupell expressed the pleasure with which he had listened to the paper, and he considered it a very great research. There was, however, one omission, and that was, the paper contained no allusion to the invasion from the Antipodes. Tasmania, and the other Australasian colonies, were preparing to extend their cultivation of fruit, and a list had already been supplied

of what the former country was able to do. He had had from the colony of Victoria a very handsome offer, if he could introduce to the colony a good dessert Apple, which could be put on the London market early. He had suggested one or two names, but our early varieties were not adapted for keeping. The sample sent out should be a good early Apple, and most pleasant to eat when taken from the tree. It should therefore be an Apple with some of the character of the King of Pippins, or the new Allington Pippin, that should meet the want. He was convinced that the supply of a good Apple created a demand, and that people when they had been accustomed to pay 4d. and 6d. a lb. for good Australian fruit, would not hesitate to pay a better price than they had been in the habit of paying for good English fruit later in the season. For that reason he should look with hope rather than despair to the prospect of our having Australia to compete with us. He was sometimes amused by the remarks made by amateurs and gardeners in the horticultural press, as to the high quality of their produce. He wished those writers could pay a visit to the establishments of P. Kay, Ladds, or Rochford. Such a visit would take the conceit out of them. He had visited the establishment of Peter Kay, and was astonished at the Grapes, the bunches being as big as horse's heads. He thought the Royal Horticultural Society might yet do a great deal for market-growers, by encouraging them, and giving facilities for exhibiting their produce at the fortnightly and annual shows.

Mr. George Bunyard said, "Mr. Asbee had advised a large increase in the plantation of Currants. Unfortunately, during the last few years a dire calamity had seized the black Currants, and the mite *Phytopus* had increased to such an enormous extent, that large plantations had to be entirely given up. Red Currants were, no doubt, very useful, but the importation of a large quantity of cheap wines had almost done away with that old English beverage, the Currant-wine. With regard to the black Currant, the trouble was that they had not been able to find anything that would kill the mite without killing the trees. As much young wood as possible should be kept on the plant. Much discredit had been cast upon this wonderful industry of fruit-growing by amateurs and others who made grievous mistakes in their methods of treatment, and did not forget to air their opinions in the gardening and daily papers. There was no risk if people would take a wise view of the question. A man should not put all his eggs in one basket, and he would find his profits remunerative. A good haul should not be expected every year. He suggested that farmers and fruit growers should combine more than they did for mutual protection and mutual benefit in fighting the excessive competition on the part of continental growers. As to Peaches, there was no doubt that the large sizes would always produce fine prices, but they should be sent to market in the best condition, and it would pay any grower better to keep his rubbish at home rather than put it upon any market. With regard to pot-flowers, the Jubilee had seriously interfered with their sale. A fever of patriotism came over the people who would only buy red, white, and blue kinds, and he had a great number of pots on his hands, which in other years were always sold out.

Mr. Asbee, replying to a hearty vote of thanks, said the Australian fruit did not touch our Apples, as their seasons in no way clashed. With reference to the Californian fruit on the table, it was grown by Mr. A. Block. Californian Pears could be sold in the London markets two weeks after they left the trees. The cost of transit for the box before then was 4s., and the cases of Pears (about three dozen), could be sold for between 8s. and 12s. per case.

The Chairman did not think the Pears' keeping quality was very good. One day, when opened, they were green, the next day they were fit to eat, and he supposed on the following day they would be rotten.

Mr. Asbee said all Pears were liable to rapid deterioration. The Conference then ended.

Scientific Committee.

OCTOBER 12.—Present: Dr. M. T. Masters (in the chair); H. J. Veitch, Rev. W. Wilks, Dr. Russell, and the Rev. G. Henslow, Hon. Sec.

Acorn Cups Malformed.—Mr. French of Felstead sent specimens of this not uncommon phenomenon. It appears to be due to an arrest of the flower, probably by some insect attack, when the scales of the cup become enlarged and free, as in the Artichoke gall.

Melons Diseased.—Specimens were received from Mr. J. Fraser Smith, of the Gardens, Cullen House, N.B., who writes as follows:—"The disease attacked my crop last year, and has done so again this, in both a sudden and deadly manner. An entire crop of twenty plants has perished in a few days. The disease first shows a spot on the leaf, then a part of the stem gets affected, and in two or three days the whole plant collapses. It is only at a certain time of the year, for the first crop in both years, which was grown in the same house, finished without any signs of it—i.e., about the early part of August; while the second crop, about half-grown on the opposite side of the path, has all gone, as also a later batch planted on the same side as the first ones. Out of thirteen plants ten went off in one day. Two young Cucumber plants have also died in the same way, after they were 4 feet high." The following report has been received from Mr. Massee, of Kew:—"The Melon disease is caused by *Scolecotrichum melophthorum*, Prill., a parasitic fungus. The disease is common in France, but I am not aware of its having previously been observed in Britain. Burn all diseased plants, for if they be allowed to

rot on the ground, a recurrence of the disease would almost certain next season. Under any circumstances would be advisable not to use the same ground for Melon growing for at least two years, as the fungus-spores probably abundant in the soil."

Parrot Tulips Seeding.—Mr. Wilks brought ripe pods of this variety, which he had crossed with the pods from other kinds of Tulips growing in his garden. It has been stated by growers that the Parrot Tulip had not been known to bear seed at all, and Mr. Henslow observed that some bulbs received from Mr. Barr, in every case the pods were abortive. It is proposed to raise plants from the seeds thus obtained.

Abies bracteata Cones.—Fine specimens were received from Mr. A. Harding, The Gardens, Orton Longueville, Leicestershire. They were borne by one of the finest specimens of this species in England. The tree is a native of South California, growing in Santa Lucia, and is in danger of becoming extinct. The cones are remarkable for their long bracts.

Calceola toona Fasciated.—A remarkable specimen, consisting of a spirally-coiled, flattened branch, two of the ends being welded together, was exhibited by Dr. Masters. The specimen came from Dr. Franceschi, Santa Barbara, So. California.

Abies balsamea.—A specimen was received from the Noble of a young plant which had developed a globe-tuber-like excrescence below the soil. Similar cases have occurred some years ago in the same grounds, but the cause is not traceable at the present state of growth, though possibly be due to some injury by insects at a very early stage.

Juniper Berries, Gymnospermous.—Dr. Masters exhibited some berries of the common Juniper, received from Schröter, of Zurich, remarkable for the three coherent berries not having become fleshy enough to close in upon the seeds so that the latter remained visible, free, and strictly "gymnospermous," as in the previous condition of the ovules.

Trapa natans, fruit.—He also showed specimens of Water Chestnut from the Lago di Muzzano near Lugano, having four knobs upon them, which do not occur in ordinary form of this fruit. Specimens of another variety, *Verbanensis*, were shown from the Lago Maggiore.

Spruce Fir-cones, var.—He also showed cones of a variety *Picea Excelsa* having smooth-rounded scales, instead of the usual form. Dr. Schröter, who gathered it from Switzerland, referred it to *Picea medioxima*; but Dr. Masters observed that this variety is a dwarf alpine or arctic species, and regarded the specimen as a variety only of the Spruce.

Anthurium Spathe, Monstrous.—Colonel Beddome sent specimens having three spathe, and the spadix commencing to branch, exhibiting a semi-proliferous condition.

Plants Exhibited.—M. Lemoine sent a spray of *Tamarix kashgarica*, interesting as being a late-flowering species from Central Asia; *Panax sessiliflorum*, with large, dense bunches of black berries, probably from Japan; the Bagu odorant having a delicate but very evanescent odour of lemon, and double and semi-double sports of *B. sans florens*.

Galls on Roots of Oak.—Mr. Wilks brought remarkable specimens forming a large mass on the roots of Oak or Chestnut. They are also found on the roots of the Deodar. The galls are polygonal and wedge-like, so forming together a globular cluster about the root. They are produced by *Cynips* (see *Gardeners' Chronicle*, 1841, p. 732, and 1874).

DEVON AND EXETER GARDENERS' ASSOCIATION.

OCTOBER 13.—The first paper of the present session, given on the above date, was one on "The Qualifications, Duties of a Gardener," the essayist being Mr. J. Mayne to the Hon. MARK ROLLE, Bilton, Devon.

To be a thoroughly qualified and competent gardener, the essayist, the youth who chooses this profession should begin at the beginning. There was a desire to begin under glass, which was a mistake, as the kitchen garden was proper place in which to lay a foundation of the practical knowledge every all-round gardener should have. After years he might be moved into the flower garden for twelve months, and then to the various departments of glass, say not less than one year with the plants, and another the fruit department. His spare hours should be mostly in reading gardening books and magazines to extend his knowledge, and in recording in a diary the operations he has engaged in during the day. Such a record, for purpose of reference, would be found of great service in after years, if kept up, would show the approximate dates of doing certain kinds of garden work, as sowing, pruning, fruit-gathering, planting, transplanting, and other duties incidental to the different seasons of the year.

His experience as a journeyman, if he attends to his duties and takes an interest in his work, will soon qualify him for a foreman's place. As a foreman, he should make himself competent to take the head-gardener's place in the absence of the latter through sickness or any other cause.

As a head-gardener, punctuality as regards hours of labour and ceasing work, unless in times of pressure, should never be departed from. Discipline among those under consideration for them, impartial treatment, full control of the determination to lead, rather than be led, should be every gardener who wants to be in the front ranks of the gardening profession. The head gardener should, as

practicable, do the thinning of fruit himself; Grapes, of course, excepted, in large establishments, where it would be obviously impracticable. He should do the packing, or, at least superintend it when fruit or flowers may have to be sent to the owner at a distance. He should cultivate the art of decoration, acquire skill in laying-out ground. He ought to make himself acquainted with the various methods of heating garden structures. He should make a point of daily practice to inspect the houses to ascertain the temperature the first thing in the morning and last thing at night during the winter and spring.

Mr. Mayne advocated moving about to various parts of the country when young, and he thought that two years was long enough in one place as foreman or journeyman under ordinary circumstances, and that a change to another place in another county was an advantage. One of the chief requirements in a head gardener was to study the likes and dislikes of his employers in what the garden produced, studying to have abundance and succession of those things most required and appreciated.

The paper was carefully prepared, comprehensive, and practical; and at the close, an interesting and useful discussion, opened by Mr. Slade, gardener to Lord Poltmore, followed. The usual votes of thanks closed the meeting.

FUNGUS FORAYS, 1897.

Those who remember the past in connection with these annual excursions, cannot help, in this eventful year, recurring to the period when the fungus hunters were most numerous, and the forays at their best, when the Woolhope Club was in all its glory under the genial influence of the late Dr. Bull, and when the crops of fungi were so large, that now-a-days they would seem to be phenomenal.

For some years past there have been comparatively few fungi, and a much reduced number of hunters. One by one the old mycologists have departed from this to a happier hunting-ground, and the few who remember the "good old times" are sad in the remembrance. This year, so far as our experience goes, there has been evidence of a partial return to the prodigality of the past. More fungi have made their appearance in the woods; the weather has been delightful for the forays, but the novelties have been few or none.

The WEST KENT NATURAL HISTORY SOCIETY held its annual Cryptogamic Field Meeting on Saturday afternoon, Oct. 2, passing along the old route from Orpington to Saint Paul's Cray Common and Chislehurst. The attendance was better than for the past year or two, and the number of species collected somewhat increased, whilst the number of individuals has not been exceeded for many years. There were no novelties to be recorded, but amongst those who attended, there appeared to be a reviving interest, which was somewhat stimulated after tea by a practical demonstration, which the writer of this notice was requested to give. From the specimens on the table, the general structure of the larger kinds was indicated, and the principal features requisite to be borne in mind in the discrimination of species. Unfortunately, the influence of one hour of such teaching once a year, is liable soon to pass away.

The WESSEX FIELD CLUB held its annual Cryptogamic meeting in Epping Forest on Saturday, October 16; and, although it was a fortnight later than it should have been to have achieved its greatest success, it was eminently satisfactory. It is an unfortunate circumstance that of late years the Foray of this Club has been fixed at too late a date. The Woolhope Club almost invariably selected the first week in October, and experience has proved that one year with another—this time is the best. On the present occasion the greater part of the day was devoted to collecting; but, as the spoils did not arrive at head-quarters until dusk, and with half-an-hour of the important function of tea drinking, it will not be surprising to learn that nearly all the collections remained in the baskets, or were piled in picturesque heaps upon the tables. Under these circumstances, no unhappy referee could do anything towards arrangement, or the discrimination of species, so that, from a scientific aspect, the labour of the day was "love's labour lost."

The same remark applies here as was recorded above, that fungi were far more numerous than they had been for years, but there was no opportunity for ascertaining whether the various baskets contained anything new or rare. We recognized, however, *Amanita nidula*, which was first found at Epping some years ago, and *Boletus durissimus*, which is rare everywhere. By favour of Mr. and Mrs. Johnson, the headquarters of this meeting was Warron Hill, where upwards of a hundred foragers were kindly welcomed to "high tea." During the evening the usual meeting was held, and the conductors were called upon to report, which, on account of the circumstance above noted, they were unable to do with satisfaction to themselves or the club. Subsequently, Dr. M. C. Cooke was called upon to read a paper on "British Mycology During Sixty Years." This history commenced with the publication of "Berkeley's Fungi" in *Hooker's Flora Supplement*, and ended with the Jubilee year. It was shown how the number of recorded species had increased, with some attempt to determine the causes of this increase. And, as of more real importance, it was suggested how the knowledge of structure, diffusion, and life-history had gradually increased and was still increasing, so that not only a greater number of species had been recorded than had ever been recorded before, but we had a more intimate knowledge of

the possibilities of fungoid life than was even suspected half a century ago.

After the reading of this paper, the Chairman and several of the speakers thereupon alluded in laudatory and flattering terms to the great influence which the writer of the paper had himself exerted on the progress of British mycology. M. C. C.

EDINBURGH FIELD NATURALISTS AND MICROSCOPICAL.

THE annual fungus foray of this Society took place on Saturday, October 2, in Newbattle Woods, near Dalketh, under the leadership of the Secretary. The Marquess of Lothian kindly granted permission to the members for this purpose, and sixty-five species of the larger fungi were collected by twenty members in less than two hours.

Among the Agarics collected may be mentioned *A. (Mycena) purus* and *galericulus*, *Hygrophorus puniceus*, *Marasmius promatus*, *Paxillus involutus*, and *giganteus*, *Intense* and numerous clusters of the wood parasite, *Armillaria mellea*, were observed; the genera *Coprinus* *Lactarius* and *Russula* being as usual well represented. *Polyporus sulfureus* and *P. lentus* were gathered, but not a single *Boletus* was found in the woods. Specimens of *Hydnum repandum* were collected, and several species of *Clavaria* and *Lycoperdon*; and among the larger *Psizae*, *P. badia* was found.

On Saturday, October 16, a Cryptogamic excursion by the same society was held in Roslin and Polton Glens, under the guidance of Dr. Watson and the Secretary. The Cryptogamic flora of these localities was examined, and among the mosses collected were *Hookeria late-virens*, *Tetradon pellucida*, and *Neckera complanata*, all in fruit; and of the less common fungi, *Fistulina hepatica*, *Phallus impudicus*, and *Craterellus cornucopioides* were obtained.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

- 0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

TRAFALGAR-DAY DECORATIONS.—As we go to press, Trafalgar Square presents a very animated appearance, being thronged with visitors. Under the auspices of the Navy League, NELSON'S Monument has again been decorated, rather less lavishly than last year, but with taste and appropriateness. A

large crown girds the column at about half its height. The crown weighs about 8 cwt., and is 6 feet in height. It is supported by an iron band, from which depend four garlands of Laurels, each about 60 yards in length, which entwine the column, also the lions, and thence to the ground. There are four exceedingly large wreaths of Laurel from various branches of the Navy League, and about the plinth of the monument there are festoons of evergreens, principally Laurel. The display of floral wreaths is not large, and the flowers used consist of *Chrysanthemums*, *Rhododendrons*, white *Carnations*, *Tuberose*, and little beside these. A very large anchor presented by the proprietors of *The Gentlewoman* in the name of the daughters of England, is pretty and rich looking. The anchor itself is composed of yellow *Chrysanthemum* blooms of various shades, over Oak leaves, and a wreath round the shank of the anchor consists of purple-coloured foliage of Maple. Across this runs the word NELSON formed by red-coloured *Chrysanthemums*. With the exception of one other wreath, there was little lettering on any of the devices. A combined wreath and anchor from the Woking branch of the Navy League is most singular. It is formed of dry, dead leaves, surmounted by a piece of blue ribbon. The whole was stitched on to a framework of wire-gauze, or similar material.

MARKETS.

COVENT GARDEN, OCTOBER 21.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

TRADE NOTICE.

MR. JAMES WILLIAMS, for the last six years gardener at Foxley, Hereford, has taken the nursery establishment of the late Robert Lamb, Caythorpe, Grantham.

NOTICES TO CORRESPONDENTS.

ARAUCARIA IMBRICATA SEED: *Araucaria*. Prepare pots (32's) by well crocking them and filling them with sandy loam, and push the seed into the surface, almost level with it to the number of thirty per pot, placing the pointed or germ end uppermost. If the soil be moist do not afford water till it has become somewhat dry, and then afford a good application. The pots should be stood in a case or frame placed in an intermediate house or pit, and a sharp look-out kept for mice. The seeds do not keep long, and they should be sown forthwith.

AZALEA INDICA GRAFTING: *A. M. B.* The grafting of these plants may be done during autumn, winter and spring, if you have stocks as thick as wheat-straw of *A. japonica*, *A. Sir Charles Napier*, or *A. alba*. The stocks must be established in small pots, and grafting may be performed as side, cleft, or splice, the end of a shoot with four or five leaves being selected as the scion. Keep in a case on a mild bottom-heat till taken. In order to raise stocks, cuttings of nearly ripe wood should be taken when almost ripe, and struck in pans of sandy peat coated with sand in a close warm case, or seeds of the desired varieties may be obtained from artificially-fertilised flowers sown on the surface of pans filled with sandy, sterilised peat, and kept in a warm pit till germinated. Cuttings, however, give the quickest returns.

CORRECTION.—An error for which others are responsible was made in our last issue, when we attributed the paper on vegetables, read at the Crystal Palace, to Mr. Martin J. Sutton, instead of to Mr. Arthur W. Sutton.

DAHLIAS: *Constant Reader*. Put the old roots in a flat hamper or box, or on the ground in a hothouse in early February, covering them slightly with leaf-mould or other light soil. The roots will soon push up a number of shoots, which may be pulled off when 2 to 3 inches long, and without trimming, placed to the number of six round the edges of a small 18-sized pot, filled with sandy leaf-mould and loam, plunging the pots in a hot-bed of 75°, and be kept moderately close for a fortnight, when they will be found to be rooted, and must be put into a less warm place. In a week or ten days pot them off singly. If you have many cuttings, pots may

be dispensed with, and the striking done on a bed in a frame. This demands that a cutting when rooted be taken up and potted forthwith.

DAHLIA FLAMBEAU: *S. W.* You would be likely to obtain it from any of the Dahlia nurserymen.

DRACENAS DISEASED: *S. G. H.* Do not continue to propagate from diseased plants, but burn them all, and start with perfectly healthy plants.

FIGUS ELASTICA: *Constant Reader*. Take cuttings of ripened wood two years old, cut into 6-inch lengths, and strike in a close case, frame, or under a bell-glass in bottom-heat of 80°; or notch and layer the shoots of an old plant.

FERN FRONDS DISCOLOURED: *C. B. G.* We are at a loss to account for the discoloration, which is not uncommon this year on Polypodium and other species. We have heard of a number of *Athyria* have been similarly affected. It may be attributed to using raw manure with the leaf mould, and consequent development of fungus, which permeated the fronds through the roots; or the cause may be drip, cold water, or cold draughts.

GRAPE: *T. S.* It appears to be an American variety, with the name of which we are unacquainted. It is a very nice-eating, good-looking Grape.

ICE-HOUSES AND ICE-HEAPS: *Subscriber*. An enclosure made with a fence, 5 feet high, of boards fitted close together at the edges, will keep ice till July and August, if the heap of it put within the wooden enclosure is well-pounded, and there are at the least 30 to 40 one-horse cart-loads. The platform on which the stack is formed should be rather above the surrounding level, and slope slightly to the outside. If the weather remains frosty, it is a good practice to throw scalding water over the heap, so as, in a measure, to close the surface with a coating of ice, and thus prevent the ingress of air. The heap should be properly thatched to the thickness of 1 foot with reeds or straw, and the sides of the fence cased with sawdust, kept in position by means of thatched hurdles or rough boards. It is best to form ice-heaps under the shade of trees, or on the north side of a wood, and whenever the heap is opened for obtaining ice, the bare spot should be well secured from the air by means of clean straw.

INSECTS: *H. J. S.* Millipedes—devourers of decaying vegetation. The holes in the Carnation-stems may have been caused by weevil-grubs.

MARKET GARDENING: *A. R. A.* The town has a brisk trade in fruit, vegetables, and flowers in the season (July—October); at other times of the year we should suppose the trade would be dull, although the town is growing, and the resident population has increased greatly of late years. The climate is mild, and hard frosts rarely occur, as is shown by the exuberant specimens of Fig-trees, *Euonymus japonicus*, Myrtles, &c., met with in the town and inland. Hardy fruit, especially Plums, Pears, Apples, and Strawberries, come from Sandwich, Faversham, and other parts of the county; the wind-swept promontory being quite unsuitable for orchard-planting, although with tree-screens of *Pinus maritima*, *P. pinaster*, *P. austriaca*, Willows, pyramidal Poplar, and Sycamore, it would doubtless answer very well.

NAMES OF FRUITS.

* Applications to name fruits are so numerous at this season, as seriously to hamper us in the exercise of our editorial duties. They entail an expenditure of time, labour, and money, of which our readers can have little idea. We are most desirous to oblige our correspondents as far as we can, but we must request that they will observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones, just approaching ripeness, and they should be properly numbered, and carefully packed. We do not undertake to send answers through the post, or to return fruits. Fruits and plants must not be sent in the same box. Delay in any case is unavoidable.

W. E. P. 1, Cox's Pomona; 2, Hollandbury; 3, Tower of Glamis; 4, Hanwell Sourcing.—*J. Laure*. 2, Queen Caroline; 3, Hanwell Sourcing; 4, New Hawthornden; 5, Claygate Pearmain.—*W. J.* A poor specimen but no doubt Alyssum maritimum variegatum.—*W. C.* The white flower and fruit is Araucaria (Phyanthus) sericifera; the rose-coloured flower is Mandaranda erubescens. Thank you, we have seen fruits of Stauntonia latifolia, and three specimens were figured in the *Gardeners' Chronicle*, February 19, 1876.

PERMANENT EGGING FOR RHODODENDRON BELLADONNA: *S. W.* Of dwarf shrubs, Rhododendron ellipticum, R. hirsutum, Azalea Davisii, A. mollis, Berle Darwini, Menziesia Irish Heath, in variety, Cornish Heath Erica vagans, E. cinerea in variety, E. Tetralix in variety, E. herbacea, Gaultheria procumbens, Pernettya mucronata, Leptospermum prostratum herbaceous plants, Aubrietia in variety, Campanula carpatia, Heuchera sanguinea, Plumbago variegata, Gentiana acaulis, &c.

SONERILA BERTOLONIA: *Amateur*. You will succeed in striking these plants from leaves in the same manner as Gloxinias are increased. You may undertake the raising of new varieties of the beautiful plants from seed, which, when the flowers are artificially impregnated, is abundantly produced and it is better to do this than to wait for natural fertilisation, which is sure to occur if the plants are not protected when the blooms are about to open the authors being specially formed for securing cross-fertilisation in this way.

SULPHURING A VINERY: *Constant Reader*. Do not for even when the Vine is at rest, it may be seriously injured by the fumes of burning sulphur. If you are determined to employ sulphur, you ought to put the Vines entirely outside.

TEMPERATURE: *J. B. Wilts.*—Recent calendar articles in these pages afford just the kind of information of which you stand in need.

VICTORIA REGIA: *G. D.* It is commonly treated as an annual in gardens, the seeds being sown in spring in a potful of loam, sunk to the bottom the water be not more than 1½ foot deep, of a tank or tub.

THE

Gardeners' Chronicle.

SATURDAY, OCTOBER 30, 1897.

"THE SCOTS GARD'NER."

MORE than one edition of this epitome of gardening as it was practised in Scotland in the seventeenth century, has been published, and it cannot therefore be considered a rare work. But the first edition, "published for the climate of Scotland by John Reid, Gard'ner," and "printed by David Lindsey and his partners at the foot of Heriots Bridge, 1683" (Edinburgh), is comparatively rare. This is a small quarto of about 150 pages and four plates, and is very well printed, though a curious mistake occurs in the paging, without, however, affecting the continuity of the letter-press. The binding is very much like that in use in England a hundred years later, only cardboard is not employed for stiffening, but the same kind of white flaky material used in England about the middle of the seventeenth century.

The book is divided into two parts—the first, "Treating of Contrivance;" the second, "Treating of the Culture of Plants." There is also an appendix, "showing how to use the fruits of the garden," and a very short Calendar. While English works of a kindred nature abound with quotations from Greek and Latin authors, this is remarkable as containing not one classical quotation. It is also free from references to planetary influences and other superstitious observances. The style is condensed, particularly in the second part, consequently a large amount of matter is contained in a small space. A few Scottish expressions are used, such, for instance, as "Aprile," "Aple," "Plume," "Turneeps," "Currans," "Mell," "delve," "stove" instead of "stew," and "sharers" instead of "slices," all still in general use in Scotland.

The first part is divided into eight chapters, of which four treat respectively of the House, Drawing by Scale, Levelling, and Measuring. The other four show "How to make Avenues and Walks;" "How to Plant Thickets and Orchards;" "How to Make the Kitchen-garden," and "How to Make the Pleasure-garden." These are the more interesting, but in the chapter devoted to the House, it is shown that the latter was used as a centre from which the Scots garden designer worked. The gardens all but surrounded the house, on the east and west sides of which were "Cherrie-gardens; a proper place also for Gooseberries, Currans and Strawberries. . . . On the south side the house there is the pleasure or flower-garden, called *parterre*; at the two sides thereof kitchen-gardens; then another walk ending in a semi-circle, leading out to the lawn or deer-park." Reid

notes that "the kitchen-garden is the best of all gardens." It was surrounded by a wall with border and walks all round, and was intersected by a walk from the house, and sometimes also by a cross-walk. "The bordures of your kitchen-garden round by the walks may be boxed with Thyme, Lavender, Hysop, Rue, &c., the next with Parsly, Strawberries, Violets, July flowers, &c. Cherrie-gardens and physick-gardens, with Sweet Brier, often cut, or Box cut three times per annum, as Aprile, June, August."

Pleasure-gardens were divided into "walkes and plots," with a "bordure round each plot." "For the orderly planting of flowers there may be three wayes."

(1). In borders of mixed plants.
(2). Also in borders, "but set five rowes of each kind cross the bordure, so as twenty-five of each sort may stand in a geometrical squair. As if you set a squair of Tulips, a squair of Boar's-ears, a squair of Crocuses, a squair of July flowers, a squair of Anemonies, and a squair of Coualsips, and so a squair of Tulips, another of Boar's-ears, &c."

(3). "Plant every kind in thickets by themselves—six rowes in the bed, the dwarfish may be eight rowes." Of wildernesses which were introduced into Scotland about this time, no mention is made, but in a plan showing the method of laying out gardens, &c., round the house, there is distinct evidence of French influence in the arrangement of avenues and drives.

The second part contains seven chapters, the first of which treats of the several methods of propagation in a manner characterised by much clearness and in detail. The following paragraph on raising plants from seeds is interesting: "Abeit I use for the most part to plant and sow every species by themselves, yet you may sometimes use mixtures, as Carrots and Radish, in one bed, because the Radish may be gone e're the Carrots require much room. Among new set Liquorish sow Onyons, Radish, Lettice, and you may sow Radish, Lettice, Parsly, Carrats, Parsneeps together, gathering each in their season; the Parsneeps will stay till winter. And drop Beet-Rave or Parsly in your Onyon beds to stay winter after Onyons are gone. Also Beet-Rave, Skirrets, Beans at considerable distance in the intervalls of new planted Artichocks, also at a great distance among Cabbages, or in the edge of the furrows of other beds." He also advises to "Sow the strong and hardy deeper than the small and tender, and sow ebbet at spring than before winter, and deeper in light than a stiff soil." In the same clear manner the author treats of cutting suckers, layers, grafting, budding, and ringing.

The next chapter is devoted to the cultivation of the soil, &c., where the "English fashion of spades" for trenching is recommended, and the different kinds of soils with manures, burning, draining, watering, and making composts are fully treated. For the latter purpose he had a pit, into which he laid "All kinds or sorts, with stratus of earth, as horse, neat sheep, pigeons, and poultrie dung, Ferns, weeds, leaves, soot, ashes, sticks, sawdust, feathers, hair, horns, bones, urine, scouring of poudes, ditches, blood, pickle, brine, sea-water, the cleansing of house, of office, &c. Let them ly by a year at least, but not above two; then take them out, and their stirre, air, mingle and work them with fresh earth, or by themselves, till they become sweet." Of manures, it is noted that—"All hot dungs and manures are proper for cold,

stiff, and moist grounds; so all rotten and cold dungs and manures are proper for dry and hot grounds. All manures that retaine moisture are for poor, sandy, and gravelly soils." Examples are added of many kinds of manures, and of "lyming," and of the crops to be grown by their help.

In the section treating of hot-beds, "barley-straw, or the same mixt with bran, because it keeps heat long," is recommended." Of watering he observes:—"If you fear dry weather, differre not too long, but water while your ground is yet moist; differre not if you mind to water at all. When you do begin, continue it so long as you find occasion." Roses for watering-pots were unknown. This is the way the Scots gard'ner watered small seeds:—"I have often made use of a handful of small straw or hay, drawn as thatch, tyed in the middle, and at one end poured water with a cup, and shaken the same that it appeared like a gentle bedewing rather than a glutting rain."

The third chapter treats of forest trees, their propagation, methods of pruning, transplanting, &c., with list of trees. We have a larger list of trees now, but in practical matters we have advanced nothing. For example, it is advised that large trees be trenched round, the roots cut in, good soil firmed round them, and the tree left for two years, when it is in a condition fit to transplant with success. Again, holes are to be prepared for all kinds of trees by taking the soil out "a year before you plant, and in summer stirr and turne their earth, that no weeds grow thereon." In planting, it is recommended "not to plant deep, for they that do but cheat themselves." The best season to plant is in early autumn, as soon as they give over growing." Regarding pruning, full directions are given as to the best methods, and to cut close in to the stems, the best times being (1), October and November, and (2), in June.

Chapter IV. is of hedges or inclosure, and the chapter following on fruit trees is extremely interesting, as showing the advanced state of hardy fruit culture in Scotland over 200 years ago. This is what the author remarks on dwarfing stocks:—"To make dwarfe Apples, graff or bud on the Paradise or any that hath burry-knots, Codlings, Redstraks, &c., dwarfe Pears on the Quince; but no Pears holds well on it (that I have tryed) save red Pear, Achans, and Longavils (Longueville), but you may re-graff for varieties dwarfe Cherries on the Morella." A few years previous to this, Evelyn Worlidge and others note that the cultivation of dwarf trees budded on the Paradise for Apples and Quinces for Pears was then a novelty, but they do not mention double grafting. On transplanting fruit-trees it is remarked, "Plant not deep, but tempt the roots by baiting the surface with dungs to make them run ebb within the reach of the sun and shoures." In pruning, hard cutting, when young, is recommended; also, not to allow too many branches to remain, but to rub off superfluous buds, and to thin about mid-summer. To bring strong-growing barren trees into a fruitful condition, some of the strongest branches are to be cut clean out the centre of the tree at mid-summer; and root-pruning every third year is stated to be effective for the same purpose. In this chapter mention is made of the "Frontinak" Grape when grown against a south wall in some years ripening its fruit.

Chapter VI. is "Of Fruits, Herbs, and Roots, for the Kitchen," "the tenderest whereof are

Melons, and are not worth the while!" The Artichok is "a fine and lasting fruit!" Peas were set "in lines five rows in the bed." Thick sowing is discouraged: "Make the holes nimbly by the lines with a dibble $1\frac{1}{2}$ inches deep and 2 inches distance from another." Strawberries in like manner were planted "5 rows in a bed," but each "stock" was kept separate. "Sellery is like Parsly, grown 8 rows in a bed." It was also blanched in beds where it was planted "3 inches in the rows," but each of these 3 feet apart. "Coleflower" it is observed "is a fine very Cole," and late heads were preserved by taking up the plants and hanging them in a dry room. Among the "Roots," Potatoes are mentioned, and it is worthy of remark that Chambers and others who mention this esculent say that it was unknown in Scotland before the eighteenth century. Reid out the tubers into pieces each with an eye, and planted in March "5 rows in the bed." Potatoes were boiled then peeled, then "Chop and bruise them well, powre on butter, and set them on a coal; and if you please, strew a little cinnamon on them." "For want of butter take sweet milk." Some sensible remarks on hoeing and weeding close this chapter.

The seventh and last chapter is "Of some Physick Herbes, Shrubs, and Flowers." Many of the "herbes" were common weeds, but "Tobacco" is mentioned. The list of shrubs is pretty full for the period; and, indeed, a longer list of these and of forest trees is named than occurs in the very rare work by the Sixth Earl of Haddington, written fifty years later. There is also a good list of flowers; and the author states that July flowers were cultivated both in beds and in pots, and were propagated from seeds and by layers, which latter method he preferred, though he also notes, "I have raised many double by seed of my own reaping." Concerning Auriculas, he says:—"Bear-ears by offsets in the spring, or when the flower is past (viz., July); they affect a good natural earth well mixt with rotten neats dung. The finer sorts loves a little shade in summer, if in pots or cases you may transport them to such at pleasure."

"Great varieties may be raised from seed sown in pots, the soil aforesaid mixt with willow earth in October; take head of deep interring bairs-ears, sow them as purslain; set the potts and cases with them at the south side of a wall till Aprile, at which time they spring, and must be now retired a little, as is said; transplant in July to flower next spring, and neglect not to earth-up such as are apt to work out of ground, namely bears-ears."

Among other flowers named are "Stock July flowers, Hepatica, Holihoeks, Constantinople flowers (Lychnis chalcidonica), Pinks, Sweet Williams, Throatwort, Bell-flowers, Tulipas, Anemonies, Ranunculoze, Cyclamin, Chalcicums, Irise, Bulbose, Narcissus, Jacinths, Hellibors, Crown Imperial, Liliacs of several sorts, Pionies, Cynosorches, Tuberoze, Amaranthus, many annuals, &c."

The appendix treats on the gathering and storing of fruit, on making wines and cyder, and concerning the various methods of using vegetables as salads, pickles, and different ways of cooking. The following paragraph occurs:—"The French fruit succeeds not well with us—in England are good Apples, but Holland for ston-fruit, especially Peaches and Cherries, and Scotland for Pears."

Of "Aples" he states there was in cultivation "hundreds for both," "table and kitchen," and of Pears "multitudes." The calendar consists

of twelve pages, a page for each month of the year. It is apparently distinct from the rest of the book, as it is paged separately, and follows the conclusion. It is, however, obviously the work of the same author.

In laying down this unique work, the reader is at once surprised at the great practical knowledge its pages discover, and filled with regret that the author did not expand some of the chapters to a greater length, and especially those treating of the various trees, shrubs, flowers, and vegetables in common use at the period he wrote. *R. P. Brotherston.*

CHRYSANTHEMUM GOSSIP.

MESSRS. J. VEITCH & SONS (LTD.).—Although not regarding themselves as specialists in Chrysanthemums, like Mr. Jones, Mr. R. Owen, Mr. Godfrey, and others whose names will readily suggest themselves to the admirer of the flower, the newest in point of introduction, as well as a choice selection of old favourites, can always be found at the Chelsea Nursery, and these as well cultivated as it is possible, considering the closely-packed surrounding area, prevalence of fog in the autumn and winter, and the proximity to the Thames. The chief of these evils is fog, which glues, as it were, the florets together, setting up "damp," and destroying the beauty of a bloom, that falls a victim to it in a very short space of time. No variety is immune, although some, owing to the closeness with which the florets are arranged, their lack of substance, and the tangled masses of them, are more than others liable to suffer from this cause.

Our steps were first directed to the light, dry, narrow, span-roofed house, containing the plants carrying specimen blooms; and here, arranged on temporary staging, is exhibited the collection of novelties of this year, and those of '96 and '95. The plants are early this year, but the flowers were lacking size, as compared with previous years, for which the abnormal weather of the latter half of the year may be held accountable. *Liscarde Gentils*, as its name indicates, is of continental origin, belongs to the so-called "hairy" race of "Mums" of the Japanese section. The florets of this variety are linear, and the "hairs" are found on the margins and points only, and mostly have a downward direction; it is a white flower. *S. C. Probin* (1897) is a fine large incurved Japanese variety, which opens of a faint pinkish tint, which increases in depth of hue in the basal florets; the centre, however, is white.

In *Royal Standard* (Jones) we have a reflexed Japanese, a flower of a bright shade of chestnut, the reflex of the florets being what is called, for lack of a better word, old gold; it is an introduction of 1897. A sport from *Vivian Morel* has central florets of sulphur-yellow, and the basal ones tinged with yellow; it is new, but not considered sufficiently distinct for general purposes. Some plants of *Modesta* with large good blooms upon them were noted.

A seedling from *Viscountess Hamilton*, and named *Mr. F. Brewer* (R. Owen), with a sulphur-coloured flower, having florets of considerable width, is a striking novelty in incurved Japanese; *Elthorne Beauty*, likewise new, is a nice rosy-lilac coloured, reflexed Japanese, which is sure to find admirers. *Amiral Avellan*, a profuse flowerer, was excellent as ever; one of the best yellows. *Lady Byron* (1896), we should class among the best snow white varieties, of regular build, an incurved Japanese; *Lord Justice Lopes* (1897) is an incurved Japanese of the palest shade of lilac. The making of fine flower was noted in *Mrs. A. F. Beavan*, an incurved Japanese of a lilac tint generally, and possessing a white central floret having a flattish contour; it is new. *King of Bucks* (Owen, 1897) is a fine rich brown flower; the Australian, *C. B. Haywood*, a fine bold looking white flower with wide florets, was in very good form. *Mrs. T. Blake* is another fine flower, weighty, and of excellent form; it is said to come best from the first crown-bud. *Emily Silabury*, a reflexed Japanese,

white of an opaque sort, was admirable. As novelty of R. Owen's raising is *Duke of Wellin*, a flower of reddish-orange tint, having broad, inc florets, has the making, as the foreman told us, a fine large flower, and we are quite satisfied with the verdict. The last true novelty of 1897 thus mentioned is *Oceana*, of Australian origin, a plant which was producing some good flowers of a yellow colour.

Of known varieties noted may be named *M. C. de Leché*, a fawn and yellow-coloured Japanese outer florets showing rose-pink, and having yellow edges; *Charles Davis*, from an early bud, yellow in bud and from the late bud bronzy-fawn; *Mrs. Harn Kloss*, a chestnut-brown flattish flower, of Davis's raising; *Souvenir de petite Aimé* and *Mutual Friend* (American, of 1895), the latter a fine, large, white-flowered variety, with florets that turn inwards at the tips.

Good flowers were remarked of *Madame Carnot*, *White Carnot*, the latter a late flowerer, and late being those selected. Some nice blooms of *Seward* were visible; this fine brown-colored variety shows a great aptitude for damping at Chelsea. *Mr. D. Ward*, a hairy flower of brownish-bronze, appeared on some of the plants in capital form, of remarkable fullness.

The large span-roofed house, in which in former years the bulk of the collection used to be housed is now given up to bush-plants carrying numerous small flowers, which are not so liable to be injured by damp as were the specimen blooms. We remarked good examples of well-furnished bush *John Swinton*, *Vivian Morel*, *Chas. Davis*, *Souvenir de Petite Amie*, *W. Tricker*, *W. Seward*, *Etoile de Lyon*, *W. H. Lincoln*, *Hamlet*, and *Coquette de Castille*. In the *Camellia* house we found equally good bushes, far superior to anything of the kind found here in previous years; and amongst the best of these were *M. W. Holmes*, *Lady Selborne*, *M. Douglas*, *Cloth of Gold*, *Mandarin*, *Mdlle. B. P.* and *Source d'Or*. These bushes naturally grow of great decorative value, affording a succession of medium-sized flowers, extending over several weeks and being well clothed with leaves down to the base, or nearly, are excellent for room decoration.

BASSET DOWN HOUSE.

THIS Wiltshire residence and manor owes its name to a family of the name of Basset, who owned a large part of the county in the thirteenth century. In the year 1657 Basset Down formed part and parcel of the demesnes of Studley Grange (which at that date was subdivided into four portions), and which prior to the dissolution of the monasteries, belonged to the Cistercian Abbey of Stanley, near Chippenham. It was consequently tithe free, as all land belonging to the Cistercians was; and it is tithe free to this day, paying a *modus* instead of tithe to the Rector of Lydiard Tregoze. The present property came by inheritance into the possession of Dr. Nevil Maskelyne, Astronomer Royal, at the end of the eighteenth century, and afterwards to his only child, Mr. St. John Maskelyne. The present proprietor is N. Story Maskelyne. For many years Mr. Story occupied himself in beautifying the place, and in moving earth from the south side of the house, so as to let in the sun and carrying to the north side in order to raise the level. For this purpose he employed gangs of men, who, at that date (from 1820 onwards) were sadly in need of work during the winter seasons, the Basset family furnishing him with men who otherwise would have been on the rates, and the pleasure glades and grass-walks on the hill were gradually dug out during many successive winters, the labour going to farming and other work when the men returned. But it remained to the present owner to continue and finish what his father had begun, bring it into a harmonious whole. He it was who formed the rockery near the mansion, and the interesting wall made of sarsen stones collected from the adjacent Downs. Some of the shrubs planted by Mr. Story have become of great size. *Thuyas* of the variety *var. plicata*, forms a fine specimen at the side of the house, and there are fine old specimens

uya orientalis, and of Juniperus virginiana here. plicata (Lobbi) and Cupressus Lawsoniana, about the year 1880, and of which several fine trees were noted, show how well the chalky marl district suits them. Some fine examples of nris var. aurea standing on the rockery and in the border, appeared as if bathed in gold at the

is Brinkworth, and by the aid of the telescope the observer on a clear day may obtain glimpses of the Welsh mountains and the Badminton Monument. Blunsden Abbey is another conspicuous object, and the tower of Cricklade Church is seen in the far distance, with Purton visible between the trees. Worthy of note is an avenue about 200 or 300 yards long, consisting

Land. The specimens of Sequoia gigantea planted on a slope do not look happy, the land being doubtless too dry for them. The Scots Fir does well in this exposed situation, and all over the place the common Box grows to a large size. Some old Cedars of Lebanon—reputed to be 300 years old—are of majestic appearance, and very fine aged Walnut trees were met with.

In 1814, £100 was offered and refused by Mrs. Maskelyne, widow of the Astronomer, for three trees, as during the time of the war Walnut timber was of great value as stocks for muskets.

In old maps of the property, an avenue of Walnuts is shown in the "Cowleaze," leading up to the house, which were cut and sold by the widow of Edmund Maskelyne, Esq.

The Mrs. Maskelyne of the present day is an admirer of all sorts of hardy flowers, which she has planted extensively in the garden, which in the summer months must provide many pleasant floral surprises for the visitor. The old and beautiful single Roses are much cherished here. The rockery, too, in its season, presents an effective feature, for it is plentifully planted with bulbs of all kinds.

A part of Basset House dates from very old days, but the north and north-east side are comparatively modern, being erected in Queen Anne's reign, or somewhat earlier, as the date 1658 occurs on an iron fire-back, whilst the south side was rebuilt in 1882.

The usual appurtenances of a country residence are seen—namely, a kitchen garden, an orchard, &c.; but excepting that these, like the rest of the grounds, show careful management on the part of Mr. Bezzant, the gardener, there was little more of general interest to chronicle. J. B.

CYRTANTHUS SPIRALIS.

ALTHOUGH described and figured as long ago as 1816 in the *Botanical Register* (t. 167), this remarkable species does not yet appear to have made much advance towards popularity. At the period referred to, it was considered to be "an extremely rare plant," and after more than eighty years, the same remark still holds good. The most peculiar feature about the plant is undoubtedly the foliage, which is of a glaucous hue and spirally twisted, the latter fact being appropriately indicated by the specific name. The flowers are scarlet, and, as may be seen from the sketch (fig. 89), are by no means small. Indeed, they are considerably larger than those figured in the *Bot. Reg.*, but this is no doubt owing to the cultural skill of Mr. F. W. Moore, of the Royal Botanic Gardens, Glasnevin, who exhibited a specimen on September 9, 1896, at the Royal Horticultural Society's meeting at Westminster. The plant is a native of Cape Colony, where it usually flowers about November. John Weathers, London.

HORTICULTURE IN MYSORE.

THE famous Lal Bagh at Bangalore has long been known as one of the finest in India, and is under the superintendence of that talented horticulturist, Mr. John Cameron, who has been there for more than a quarter of a century, and it is due to his fostering care that these beautiful gardens have reached their present state. Mr. Cameron has issued an interesting report for the past year, from which we reproduce a few extracts on another page. It will be noticed that Vine-culture is carried on at Bangalore and Seringapatam most successfully. The famous Muscat of Alexandria, which is held to be one of the finest Grapes in cultivation in Europe, is successfully grown in Bangalore. Indeed, table Grapes of excellent quality, such as the Black Hamburg, White Frontignac, and the well-known Hubshee, or Black Grape of Aurangabad, have been grown at Bangalore for years, and it was, says Mr. Cameron, partly due to this fact that the Mysore State wished to extend the operations of viticulture generally in the Maharajah's dominions.

The experiments with fodder-grass in the discovery of a new ornamental plant have been identified as *Thysanotus*.

FIG. 89.—CYRTANTHUS SPIRALIS: FLOWERS SCARLET.

my visit last October. In the border near the purple Clary (*Salvia Solarea*) was a conspicuous object in flower, as was the dark purple *Aubrieta græca*.

The house and grounds occupy a site on the side of a hill, and terraces, and avenues, and serpentine paths surround it, with a very pleasing effect.

At a height of about 200 feet above sea level, the grounds are over an extensive valley; to the left

of Limes and Mountain Ash planted about fourteen years ago, with an undergrowth of old English Yews, the whole being most luxuriant in growth. Basset is a wonderful place for Beech and Elm, and fine specimens are common. The Oaks are but few, and these were of stunted proportions, showing that the soil is not to their taste.

A fine specimen of a Thorn, some 10 feet high, is interesting as having been brought from the Holy

perennial grass, and grows luxuriantly in the moist districts of the Malnad; and would, Mr. Cameron thinks, afford a large out-turn of forage. It is indigenous to the sub-tropical Himalayas, where it attains a height varying from 4 to 12 feet. Cattle, he tells us, are very fond of the whole herbage, and the culms remain green throughout the year. Mr. Cameron is also experimenting with some new trees, among them a new species of *Zizyphus jujuba* from Mauritius, which should prove an acquisition, if it can be acclimatised. *Indian Gardening.*

COLONIAL NOTES.

JAMAICA.

"THE Botanical Department of the island of Jamaica is fully described by Dr. Morris. It has done excellent service in the development of various industries, and has no doubt helped the sugar industry, also by attention to the best methods of cultivation, and by endeavouring to improve the canes. It has also imparted knowledge of cultivation to the peasantry. These efforts should be continued, and there seems no reason to alter the constitution of the department or its relation to the local government, but a competent agricultural chemist is required to be constantly employed in conjunction with the botanical department in analysing the soil and its products.

"For more than 100 years valuable economic plants have been systematically introduced and distributed through every part of the island. For this purpose, and for affording information regarding their cultivation, the island has maintained a Department of Gardens and Plantations under capable and experienced men, who have carried on experiments, and, while supporting the old, have encouraged the starting of many new and promising industries. The average expenditure for industrial purposes on the Jamaica gardens, which are established at various elevations from sea-level up to 5000 feet, during the last thirty years has not been less than £5000 per annum. Further, the Government has fortunately been administered during that period by progressive and able Governors, who have consistently adopted a policy whereby it was possible to extend railways (185 miles), establish telegraph lines (685 miles), improve communication by main roads (1879 miles), and provincial roads (3600 miles), practically reaching every part of the island. A weekly steam communication has been maintained round the island, completing the circuit in 120 hours; while the steam communication with Europe and the United States, especially the latter, is of the most frequent character, and, with one exception, carried on without the payment of subsidies.

"The capacity for further development is undeniable, for only about one-fourth of the cultivable area is actually under crops. If, as is possible under suitable circumstances, the value of either the sugar crops or the fruit trade was doubled, Jamaica would then be in as prosperous a condition as regards the money-value of its exports as it ever was in the days of slavery. But as regards the general comfort of the inhabitants, their social condition, and civic efficiency, Jamaica was possibly never better situated than at present.

"Practical demonstrations and lectures are regularly delivered in certain districts by the officers of the Botanical Department. These include such important points as the cultivation and preparation for market of Coffee, Cacao, Oranges, Kola, and Grapes; the methods of dealing with various kinds of soils by digging, draining, liming, and manuring. It is stated that, although these demonstrations are chiefly intended for small settlers, it is gratifying to find that they are attended also by owners of estates. The Botanical Department issues a monthly *Bulletin* dealing with agricultural and horticultural subjects of local interest, and gives hints with regard to the treatment of insect and fungoid diseases of plants, and the cultivation and curing of all a 'ricultura'.

products likely to be suited to the island. Further, an industrial school is attached to the Hope Gardens, where the boys attend school for two hours daily, and at other times receive practical instruction from the superintendent in pruning and budding, and in the details of the routine work of the garden. Much good is likely to arise from this practical teaching, and especially if arrangements are made to retain the boys who show special aptitude as apprentices in the gardens, after they have attained the age at which they must leave the school. Apprentices from Lagos were lately trained at Jamaica for service on the West Coast of Africa. These are now engaged in agricultural work in their own country." *Report of the West Indies Commission.*

BRITISH GUIANA.

"The gardens at Georgetown, it may be mentioned, are amongst the most attractive and beautiful of any in the tropics. The Superintendent has contributed valuable information respecting the resources of the colony, and he has distributed numerous plants for experimental cultivation amongst all classes of the community. He has also taken an active part in the agricultural experiments carried on in conjunction with Professor Harrison to improve the sugar-yielding properties of the cane, and the application of suitable manures. The most promising canes are distributed from time to time amongst planters, and the appreciation of the work done in this direction was prominently brought under the notice of the Commission.

"The following table indicates the number and value of the plants sold from the Botanic Gardens during the last fourteen years:—

Year.	Plants.	Value.
		Dols.
1883	11,285	824.28
1884	12,360	1,431.31
1885	10,831	1,632.07
1886	No register of numbers	1,160.10
1887	7,778	743.29
	11 Warden cases, and 13 tons Sugar-cane	
1888	6,518	718.17
1889	6,196	665.08
1890	7,258	1,423.29
1891—2	5,685	964.42
1892—3	6,962	1,436.03
1893—4	4,608	1,093.19
1894—5	5,424	975.59
1895—6	6,222	699.88
1896—7, Jan. ...	19,765 and 23 loads and 4 barrels Sugar-canes	600.42
	110,892	14,427.12

"The large quantities of seeds, seedlings, and cuttings disposed of every year are not included in the above.

"When the interior lands are in course of being settled, it will be found desirable to establish branch-gardens in certain districts for the purpose of supplying seeds and plants to those starting new industries, and to furnish them with selected fruit-trees, such as grafted Oranges, Grape-fruit, Mangoes, &c. These would not be obtainable by any other means. The men in charge of such branch establishments should be competent to advise as to the selection and treatment of soils, and to afford hints in regard to the requirements of new or little-known plants. Later on, one or two agricultural instructors might be added to the staff, and these would devote themselves, as in Jamaica, to the work of visiting and instructing settlers, and giving practical demonstrations in grafting and pruning Orange and other fruit-trees, Coffee and Cacao, and in simple and inexpensive methods of preparing crops for market. The progress made under the stimulating influence of such agencies would soon repay the cost. There is ample evidence of this in the rapid development of new industries which has taken place in other countries." *Report of the West Indies Commission.*

THE ROSARY.

ROSES OF BRITISH ORIGIN.

THIS subject is already a comprehensive one, it is extending every year. We no longer depend upon France for our hybrid perpetuals, by Chinas, and Teas, for the Roses we derive from British rosarians are quite equal to any of the essential creations or "introductions." Amongst latter, for example, it would be impossible to cover finer productions, in their own special class than Mrs. Sharman Crawford or Mrs. John La Duke of Edinburgh, Prince Arthur, or Duke Albany; Muriel Grahame, Devonensis, or Sou de S. A. Prince. Neither France nor Germany given us a grander Rose for garden-decoration. Viscountess Folkestone, though doubtless Kaiserin Augusta Victoria (which has not its fragrance or same marvellous facility in flowering) is more perfect in formation. But, on the other hand, if its form is superior, and its petals more closely compact, it is more exacting in its demands. It absolutely requires, according to my experience, a dry, warm season for the revelation of its floral capability, and this, at least in our somewhat trying Scotch climate, where moisture is superabundant, and supply of sunlight often extremely limited, is a serious limitation. But where atmospheric influences smile upon its development from bud to perfect expanded blossom, Kaiserin Augusta Victoria is a glorious flower, of noble dimensions, and tender Primrose-hue.

WALTHAM ROSES.

Roses of British origin cannot adequately be discussed without some appreciative reference to the which have been originated at Waltham Cross. It is interesting to remember that all of the varieties whose names are inseparably and most honourably associated with that of the veteran rosarian, William Paul, have been given to the world during Victoria's reign. One of them, whose great merit have often emphasised, bears the name of the late Duke of Albany, who may be said to have inherited from both of his illustrious parents his love of horticulture. Duke of Edinburgh, which has yet been entirely superseded, was raised at Cheshunt when Mr. William Paul and his elder brother the late Mr. George Paul, were equal partners in the firm bearing their name. Of Waltham Cross Roses, the most famous are probably the following varieties, viz. Beauty of Waltham, sent out in 1859 and still much admired for its shape and brilliant complexion; Crown Prince, a beautiful and very fragrant dark hybrid perpetual, which has always been a favourite with the French rosarians; Duchess of Albany, a valuable, deeper shaded derivation from France; Duke of Albany, already characterised; Gordon, a clear-complexioned modification, in probability, of Madame Victor Verdier; Gr Mogul, which has the formation of A. K. Waltham, though not so reliable; Marchioness of Lorne, most accommodating, and richly odorous Rose, which in a very cold eastern exposure, succeeds admirably here; Pride of Waltham, Star of Waltham, W Lady, and Medea, the finest of British yellow of greater substance than Madame Hoste, and more impressive in form than Perle des Jardins. Duke of Bedford and Countess of Rosebery, though introduced by Mr. Paul, were not raised by him. At his later achievements are Sylph and Sappho, Queen Mab, and Duke of York, Enchantress, and Empress Alexandra of Russia, whereby his reputation fully sustained.

CHESHUNT ROSES.

The Roses raised at Cheshunt have also been numerous, and it may truly be affirmed that the majority of these have proved of the greatest value either for effective exhibition or garden cultivation. It would be almost superfluous to speak of the merits of such varieties as Mrs. Paul, the grand the Bourbons, surpassing even the venerable Sou de la Malmaison in general effect; while Mrs. Paul is supposed to be derived from Madame Isaac Paul is a notable example of the law of variation.

of Teck and Cheahunt Scarlet, both brilliant acquisitions, though not, perhaps, so impressive as their predecessor, Duke of Edinburgh; Charles Gater (whose name is commemorative of Mr. George Paul's foreman), a hybrid perpetual of loveliest velvety hue; Glory of Cheahunt, and Duke of Connaught; Carmine Pillar, a splendidly decorative climbing Rose; and Reynolds Hole, described to me in a letter by the Dean of Rochester as "uncertain, coy, and hard to please, but exquisitely lovely when in good humour."

BENNETT'S ROSES.

Of the late Mr. Henry Bennett's creations, the most important are Mrs. John Laing, H.P., and Viscountess

tively by Mr. J. Cranston of Hereford, and the Messrs. Turner of Slough, of whom the latter have been the introducers of the Japanese Crimson Rambler, whose success has been extraordinary. Mr. Benjamin R. Cant has given us Prince Arthur, a great improvement on General Jacqueminot. To Lord Penzance we are indebted for his beautiful and fragrant Hybrid Briars, of which the most precious are Lady Penzance, Brenda, Flora Molvor, Meg Merrilies, and Jeannie Deans; while from the Messrs. Cooling, and Mr. Alexander Hill Gray, of Bath, we have received Lawrence Allen, and that graceful, miniature form of William Allen Richardson, Allister Stella Gray, which I find more fascinating than its parent Noisette.

easily burned, while the latter equally demands a warm climate, as it is difficult of expansion by reason of the number and close compactness of its petals. Miss Ethel Brownlow and Mrs. James Wilson, two admirable and highly contrasted Teas, the latter having the habit of Catherine Mermet. Helen Keller, of beautiful roseate hue, and Mrs. W. J. Grant, of which the latter is very fascinating when the flowers are half blown, a lack of fulness being manifest when their entire dimensions have been attained. Muriel Grahame, introduced but not originated by the Irish rosarians, which has been derived from Catherine Mermet, and bears a very conspicuous resemblance to The Bride. Marjorie, though not of strong growth or very prolific, is one of the sweetest of modern hybrid Teas. Marchioness of Londonderry is, by reason of its ivory white colour and commanding dimensions, a most impressive Rose; it is extremely susceptible to the influence of rain. The Marchioness, for this special reason, is not so well adapted as her beautiful sister, Margaret Dickson, for garden ornamentation, and therefore is essentially an "exhibition Rose." David R. Williamson.

VITIS COIGNETIÆ (?).

OUR illustration (fig. 90) shows a leaf and tendril of a fine species of *Vitis*, useful chiefly as a decorative plant in this country, so far as we yet have any experience. The leaf and tendril are figured from a plant shown by Messrs. J. Veitch & Sons, Ltd., Royal Exotic Nursery, Chelsea, at a meeting of the Royal Horticultural Society on October 12 last. The plants were growing in pots, and they possessed ripening foliage of fair size, and of a ruby colour.

The plant has hitherto been regarded as difficult of propagation; but from the following note, taken from Möller's *Deutsche Gärtner Zeitung*, we learn that the Vine is quite hardy in Germany; planters in this country need have no doubts of its hardiness. If that be the case, it is a much hardier plant than any variety of *Vitis vinifera*, which the frosts of an ordinary German winter kills to the ground, and sometimes to the depth of 6 inches or a foot in the absence of a heavy coating of snow, or a thick mulch of tree-leaves, Fern, &c. In our country, it would be a winter of remarkable severity that would injure unprotected shoots, if these were well ripened. The plant has always presented difficulties to the propagator; but according to Mr. Rettig of the Jena Botanic Gardens, eyes of ripe wood taken early in the new year and split in half, and placed in pans filled with loam covered with sand, and plunged in a hot-bed of 80°, strike without the least trouble.

It should be stated that the Vine shown by Messrs. Veitch under this name is not the same as that grown by Mr. Anthony Waterer, nor is it the same as that originally introduced from Japan by Madame Coignet; the leaves of which latter are more leathery, and thickly covered with fawn-coloured down on the under surface.

AUTUMN FLOWERS AT BELVOIR.

POLYGONUM VACCINIFOLIUM.—We have in this Himalayan plant one of the prettiest imaginable things for autumn flowering. It is good for planting on the rockery and stony banks. Although introduced in 1845, the plant is still far from common in gardens. I had almost called it the prettiest member of the Polygonum family, but others might disagree with this opinion concerning a group of plants which differ so much from each other as Polygonums do. One has only to contrast the little wiry *P. aviculare* of our fields and roadsides with the stately and graceful *P. cuspidatum*, in order to realise the great difference there is in stature and general appearance of the various species. *P. vaccinifolium* is a dwarf species, having thin, wiry stems which creep over the rocks, and hang gracefully over ledges; and the plant is now—October 20—covered with small 3-inch spikes, bearing flowers of a bright pink colour. It is a "good doer," and has the additional merit of not straying far from the spot where it is planted, and not over-running its boundaries like *P. cuspidatum*.

FIG. 90.—*VITIS COIGNETIÆ*, (?) HORT. VEITCH; SMALL LEAF DEEP ROSE-COLOURED ABOVE, GLABROUS BENEATH.

Folkestone, H.T., to which, as invaluable varieties for garden culture (the former being also indispensable for exhibition), I have already referred; Princess of Wales and Princess Beatrice, very beautiful Tea Roses, but difficult to grow adequately, and very sparing of their blooms; Heinrich Schultheiss, the parent of Mrs. Harkness, obtained by the eminent firm bearing that name; Captain Hayward, a crimson H.P., of great effectiveness in the garden, but not very full; and Clara Watson, which for many years I have regarded as the grandest of the hybrid Teas—this year I had it nearly 6 inches in diameter.

ROSES OF VARIOUS ORIGIN.

Among other notable Roses of English origin are the Crimson Bedder and Mrs. Harry Turner, raised respec-

tively by Mr. J. Cranston of Hereford, and the Messrs. Turner of Slough, of whom the latter have been the introducers of the Japanese Crimson Rambler, whose success has been extraordinary. Mr. Benjamin R. Cant has given us Prince Arthur, a great improvement on General Jacqueminot. To Lord Penzance we are indebted for his beautiful and fragrant Hybrid Briars, of which the most precious are Lady Penzance, Brenda, Flora Molvor, Meg Merrilies, and Jeannie Deans; while from the Messrs. Cooling, and Mr. Alexander Hill Gray, of Bath, we have received Lawrence Allen, and that graceful, miniature form of William Allen Richardson, Allister Stella Gray, which I find more fascinating than its parent Noisette.

IRISH ROSES.

Many Roses of distinction have come to us from the Royal Nurseries of Messrs. Alexander Dickson & Sons, at Newtownards. Of these, the most attractive are Mrs. Sharman Crawford, an exquisite pink Rose of upright habit, fine form, and great floriferousness. Earl and Marchioness of Dufferin, of which the former requires a cool season, as its petals are

CRINUM POWELLII.

This bulbous plant affords a welcome variety in the herbaceous border, both in regard to the foliage and the flowers, and will be grown extensively when it is better known. Its flowers, which are fragrant, are freely produced in September and October in this garden on stems 3 feet in height, with ten to fifteen flowers in each corymb, and they are of a deep pink colour outside, and pale pink within, appearing at some distance like a cluster of large pink Lilies, opening in succession for several weeks. The plant is undoubtedly hardy, it having withstood the severe frosts of 1895 without serious injury; but as a precaution, the ground around, and the bulb itself, should be covered early in November with a heap of half-decayed leaves, when, if the frosts are severe, the plant dies down only so far as the covering. Our plants are growing in a light mixture of leaf-soil, sand, &c., overlying a strong deep clay. Will any of the readers of this kindly afford me the history of this plant? [A cross between *C. longifolium* and *C. Moorei*. Ed.]

PHYSOSTEGIA VIRGINIANA SPECIOSA.

Dracocephalum of some gardens. A native of North America, this plant grows to a height of 4 to 6 feet, and is very distinct from the other occupants of the herbaceous border; the stems are furnished with numerous spikelets of flowers, which are in colour lilac and white. It lasts in flower for several weeks; and if it cannot be regarded as a showy plant, it is pretty, and its general effectiveness is enhanced by the crimson-purple colour of its stems.

PHYSALIS ALKEKENGI.

We find this plant affords a welcome bit of bright colour at this season, which continues until severe frost cuts down the plant. It is a plant of easy culture, reappearing regularly every spring when once planted and left undisturbed. The patch should have a light top-dressing annually in the spring, and some amount of thinning of the plants performed a little later. For indoor decoration, this species, and the variety *Franchetti* with bigger calyces, make capital subjects, and keep in good condition for a long time without water. *P. Franchetti* has not been a success hitherto at Belvoir, for although the plant grows freely, it does not ripen its fruit out-of-doors. Whether it requires more heat in summer than the old variety is uncertain, but it appears to be quite as hardy, and is worthy of extra care and attention in order to secure its fine large fruits. *W. H. Divers, Belvoir Castle Gardens, Grantham.* [In the more southerly shires, *P. Franchetti* ripens its fruits perfectly in fully exposed spots in the open, and even when the plants are crowded together they flower abundantly, and set well. Ed.]

GRAPE VINES AT NORWOOD, ALLOA.

THE residence of Thomson Paton, Esq., is well known for the public-spirited munificence of its proprietor in all that concerns the interests of the town and neighbourhood, such as the establishment of public libraries, reading-room, baths, technical institutes, &c., and the fame of its Grapo-growing, general fruit and flower culture, and landscape furnishing under the able management of Mr. Kirk, Mr. Paton's gardener. Having seen and heard so much of his Grapes, the writer was naturally eager to see them at home for himself. Hence he soon found himself passing through the pleasure-grounds which cover some 20 acres, en route for the kitchen garden of about 1 acre, well stocked with fruit-trees and vegetables, and containing the famous vineries, two orchard-houses, two Melon-houses, Pine, Peach, and Nectarine-houses, &c. There are four vineries, each 24 feet long by 14 feet wide. These were planted in 1888. Each vinery is planted with seven Vines. The early vinery was furnished with three Black Hamburgs, two Madresfield Court, one Buckland Sweetwater, and one Foster's Seedling. The Grapes here were all cut except Foster's Seedling,

which were fine in bunch and berry. The leaves and such young wood in the early house were all that the most sanguine could desire.

The second vinery is mostly devoted to so-called varieties of Muscats, among which were Bowood and Tynningham Muscats, Muscat of Alexandria, Muscat Hamburg, and one rod of Mrs. Pearson; the major part of the crop here was already cut, but those that remained sufficed to show the splendid character of the Grapes and the size of bunch, and especially of berry.

In the third vinery were fine examples of wood, leaf, bunch and berries. It was also filled with a most suggestive and interesting variety of sorts. There were three Gros Colman, one black Hamburg, one Golden Hamburg, one Madresfield Court and one Trebbiano. It is interesting to note that white and black Grapes are here interworked on each other with the best results, without changing their colour, or greatly modifying their character.

The new Grape Lady Hutt grafted on Colman was finishing four bunches over 6 lb. in weight; while Appley Towers also on Colman were carrying bunches 5 lb. in weight and as black as sloes. The Duke of Buccleuch grafted on Trebbiano, was carrying fine bunches over 5 lb. in weight; Mrs. Pearson grafted on Colman was also very fine here; while Black Hamburgs in this vinery were models in bunch, berry, colour, and quality.

The fourth vinery is planted with two Lady Downes, one Alnwick Seedling, one Alicante, one Gros Guillaume, one Gros Maroc, and one Cooper's Black, the last two being considered synonymous. In density of bloom, form, and quality they are equal. In this house is also to be seen a very promising amber-coloured Grape, Kirk's Seedling Duke, grafted on Lady Downes; likewise a black Duke. Madresfield Court is a superb Grape in bunch and berry, grafted on Lady Downes. Muscats, Hamburgs, with fine bunches, and abnormally large berries, grafted on Alicante; Appley Towers and Black Hamburg are also grafted on Alnwick Seedling, and are superb in size and quality; and the Duke of Buccleuch is at its best, and a grand best it is, on Gros Guillaume.

Two points strike visitors to the Norwood vineries. Mr. Kirk, their skilful manager, is a fervent believer in the mixture of Vine-blood. Nothing can be too good or fresh in scion or stock with which to reach perfection in bunch, berry, colour, quality, size of leaf, strength, and hardiness of wood. The second point is, that all his blends, crossings, and mixing of Vine-blood seem eminently, and to the mere visitor, all successful; but doubtless, to Mr. Kirk each cross has its own special message and meaning, some of which he will probably find time to reveal to his brother growers at an early date.

Meanwhile, the general lesson that seems to lie on the surface of all these crosses, appears to be this:—The more we cross our vines, the bigger and better our Grapes; though some affirm that skill and care, rather than grafting and crossing, are the parents of the victories reaped in vine-culture at Norwood, and doubtless these are main factors of success here as everywhere over the wide field of horticulture. Others, again, affirm Kirk's manure does it all. Having learned the wants of his vines in the school of long experience, and assisted by his son, a chemist in London, who more likely to make a perfect food for his favourite vines or other plants? Hence, Kirk's Vine-food or manure has proved itself a well-balanced and powerful fertiliser, rich in organic matter, ammonia, potash, and phosphates. But the fruits of these Vines, their vigour, their produce, and the prizes they take, are the results of skilful culture, crossing, and feeding combined. Near the vineries are some nice Pine-stoves, a house of fine Tomatos (the Comet), another of a good Brown Turkey Fig, Cucumbers, and two houses of Orchids, one mostly *Odontoglossums*, and the other *Cattleyas*, *Dendrobiums*, &c.

Passing from the higher to the lower gardens through the well-furnished flower-gardens, borders, and shrubberies, we come to the lower range of glass near the mansion. Here is an early Peach-house 24 feet long and 14 feet wide, furnished with fine

trees of Waterloo and Royal George Peaches, and the back wall with Lord Napier Nectarine, in robust health, and that carry fair crops every year.

The late Peach-house is 30 feet long by 26 feet wide, the extra width furnishing space for utilising to the full the front roof trellis and the entire back wall of the house without injury or excess of undue shade to either. The front trellis is furnished with fine Peach-trees of the Dymond, Barrington, and Sea Eagle Peaches, some choice fruit remaining at the time of my visit; the back wall being clothed with Humboldt and Pine-apple Nectarines.

Passing through a large greenhouse, well furnished with Azaleas and other useful hard-wooded plants, we enter a beautiful orchard-house, 30 feet by 24 feet, and sufficiently lofty to give it a specially light and elegant appearance, filled with Pears, Apples, Plums, and other fruits, grown in 11 and 12-inch pots. The plants were in perfect health, carrying from a dozen to fifteen and twenty good fruits apiece.

Passing through this attractive orchard-house, we enter the large conservatory attached to the mansion. It contains a huge *Dicksonia antarctica*, said to be the finest in Scotland, and many other choice specimens, and was glowing with Begonias, Cannas, and other showy flowers and plants. Near this is a well-stocked plant-stove, crowded with choice greenery, Palms, Ferns, variegated plants in 6-inch pots, such as *Pandanus*, *Crotons*, *Dracenas* for house, room, and table decoration.

But my time was exhausted, though by no means the charms and resources of this chastely-disposed and tastefully and profitably furnished demesne. But having gone to Norwood primarily to see the Grapes, and help others to see them so far as possible by proxy through your pages, and having seen them, to my great pleasure and profit, my present duty ends with heartily thanking Mr. Kirk for his great courtesy and kindness. *D. T. Fish, 12, Fettes Row, Edinburgh.*

FLORISTS' FLOWERS.

THE AURICULA IN AUTUMN.

A GENERAL consent on the part of growers asserts the fact that Auriculas in pots have on the whole done remarkably well this season. Somehow or the other, variable as was the weather, it appears to have suited the plant. My own plants are in full leafage, though a few of the basal leaves are turning yellow, showing that the time is coming when they will enter their rest period. All through the hot dry weather, the plants if looked after in the matter of water, remained clean and vigorous; but very little seed was obtained even from fertilised flowers; the dry hot atmosphere of even a north house in such weather appears to have dried up the pollen. A good growth followed upon the longest day, but few autumn trusses, so far have put in appearance, and there has been scarcely any boxes of plants. Some varieties deteriorate rapidly unless potted soon after blooming, and have every attention; but these have remained in good growth, and so I am justified in stating that the plants have done remarkably well on the whole.

He who would be successful as a cultivator of Auriculas must be prepared to give his plants proper attention at all seasons of the year. Just now, while the weather is fine and dry, water is needed; the pots are becoming filled with roots, and if the drainage be good, and it should always be so, water soon drains away. This is an essential condition of good health. Deficient drainage, and a water-logged soil, injure and destroy more plants than does anything else. Given clean pots, a suitable soil, healthy plants, perfect drainage, and fresh air, and the culture of the Auricula is by no means difficult. All that is desired is a round of necessary attention to keep the plants in the way they should go. It is the usual practice to keep the decaying leaves removed. I do it at this time of the year in the interest of order later on. When frost sets in, I allow the decaying leaves to remain on the surface of the pots all the winter. I may be wrong in doing

so, but they appear to me to be a kind of natural protection, and I have seen in the case of many hardy plants in the open how their decaying leaves afford them protection during the winter. Then in spring, as soon as there are signs of the beginning of the annual forward movement, the leaves removed, the surface soil stirred, and in some instances replaced with fresh, water given if necessary, and then they seem to sail ahead majestically along the sea of promise.

A treacherous grub, which appears to suddenly put in appearance, and which after nibbling at a few of the outer-leaves, makes for the heart of the plant and eats its way to the centre and devours it, needs sharp looking after; the months of September and October appear to be its chief feeding-times. No quarter to this grub should be the rule of the Auricula-grower. Green fly is active, just now particularly so. It is astonishing how this pest increases under any relaxation of energy in keeping the plants clear of it. A camel's-hair brush can be used to disturb the marauders, subjecting them to a forcible ejection; if they make headway, a fumigation with the XL vapour, which I have always found an excellent insecticide, or by means of tobacco-paper or rag, should then be applied.

As the plants fall away to their winter's rest, water may be gradually withheld; but I am by no means in favour of keeping the soil about the roots

land's gardens at Syon House, where a succession of gardeners have been fortunate in securing pods in quantity, and also at Osberton in Mr. Bennett's time. Mr. Bennett laid stress on getting the wood well ripened, and to ensure that, he almost parched the plant. The failure to fruit is due in most instances to a lack of knowledge of the method of fertilising the stigma. In the flowers of the Vanilla, besides the petals and sepals, there is a column to which the anther and stigma are attached at the summit (see fig. 91). The anther is a dilated organ attached to the summit by a curved process, and contains the pollen-masses within a cavity on its lower surface. The anther by means of its curved neck, is directed downwards, and rests upon the so-called rostellum, which lies between the anther and the stigmatic surface, and thus prevents all contact between them. To effect fertilisation, the rostellum has to be removed by means of a pair of pointed forceps, which must be introduced sideways between the anther and stigmatic surface, so

Forget-me-Not, the plants forming little tufts, as in *Spergula pilifera*, from whence springs up an abundance of delicate sky-blue flowers. It comes true from seed, blooms uninterruptedly from May until frost, and is admirably adapted both for borders and for pot-culture. (See fig. 93.)

MESSRS. HAAGE & SCHMIDT, ERFURT, OFFER—

Campanula mirabilis (Alboff).—The most beautiful of all Bell flowers, discovered by Mr. Alboff in the Caucasus. Horticulture has to thank Mr. William Barbey's generosity for the introduction of this magnificent plant. It belongs to the section of *C. medium*, but has little resemblance to any of the *Campanulas* cultivated up to the present day. Being densely branched from the bottom, it forms a low pyramidal bush of about 2 feet in diameter; each branch, even the smallest, produces a great number of large flowers of a pale blue or lilac colour. The plants, when in full bloom, present a regular flowering pyramid of at least a hundred blossoms open at the time. The singular leaves are hard and leathery, garnished with thin and sharp teeth at their edges. The radical leaves, forming a rosette, differ greatly in shape of those appearing on the stems; the former are oval-spatulate, the lower ones of the latter are stemless, oval-oblong, the upper ones round-heart-shaped.

Delphinium speciosum var. *glabratum* (Stapf).—Handsome new hardy perennials Larkspur from the

FIG. 92.—ANGELONIA GRANDIFLORA ALBA.

FIG. 93.—MYOSOTIS PALUSTRIS TOM THUMB.

so dry as some people advocate. I do not think anyone ever lost an Auricula through the moist soil in the pot becoming frozen during the time it was severe; but I have had the fine root-fibres destroyed by keeping the soil too dry. Only let there be a porous soil and free drainage, and there will then be very few indeed of pots with waterlogged soil.

It is not too late to re-pot young stock, provided that the balls of soil are not too much reduced in making the shift. Such seedlings as need pricking-off from seed-pans should be transplanted without delay, so as to enable them to become active before Christmas. At this time of the year slight shifts should only be given, say, to a pot only one size larger. I am in favour of two pottings—the first as soon as possible after blooming, trimming the roots where necessary, and transferring the plants to a small-sized pot; and then early in September re-potting to a larger size in fresh soil, without disturbing the balls of roots. They have the autumn to make fresh roots, and by the spring are well established in the fresh soil. R. D.

as to pull it away in the direction of the former. The pollen-masses are then drawn out and pressed down on the latter, and the operation is completed. Doubtless many of our readers would be pleased to read Mr. Wythes' methods of cultivating the plant at Syon.

CONTINENTAL NOVELTIES.

MR. ERNST BENARY includes among his novelties the following, of which we condense the descriptions from his Catalogue:—

Angelonia grandiflora alba (Benary).—The *Angelonia grandiflora* is a graceful greenhouse-plant, of aromatic odour, and bearing lilac flowers, which appear the same season as the seed is sown. The first variety, which I have now obtained, is more beautiful than the type, its numerous pure white flowers standing out in contrast with the elegant dark-green lanceolate foliage. This plant is especially adapted for room or conservatory decoration, being a good winter bloomer, and it also makes a charming ornament for the table. (See fig. 92.)

Myosotis palustris Tom Thumb (Benary).—This is quite a pigmy form of the widely-known Marq

Himalaya mountains. The green leaves are radical, palmately-lobed, the lobes toothed and out; inflorescence corymbose, 2 feet in breadth by 3 feet in height, branches spreading; flowers silkily hairy, 1½ to 2 inches across, and of a beautiful dark azure-blue colour. Similar in growth of the plant, and also in the shape of the flowers, to the *Delphinium cashmerianum*, this new Larkspur differs essentially by its larger inflorescence, and by the more opened, star-like, and longer-spurred flowers.

Primula capitata (cashmeriana) alba.—New white-flowering variety of this earliest-blooming Primrose, reproducing itself true from seed. The flower-heads are much larger than those of *P. denticulata* alba.

Primula floribunda grandiflora Isabellina.—While the type of this extremely free-flowering Himalayan *Primula* produces flowers of a rich canary-yellow, our new well-fixed variety bears flowers of a soft and very pleasing pale sulphur, contrasting beautifully to the green foliage. If sown in a greenhouse in January or February, the seedlings will commence blooming in June, and will continue so without interruption during the summer and winter months. Splendid plant for the culture in rooms or in a cool-house.

Rudbeckia bicolor superba.—This new annual variety represents a welcome addition to the collection of these popular annual and perennial plants, so extensively used for cut flowers at present. Growing about 2 feet in height, it forms a many-branched, dense bush, and produces its long-stemmed flowers

THE FRUITING OF VANILLA PLANIFOLIA.

MANY gardeners grow, or at any rate they used to grow, this plant commonly in the stove, but it was rather rare to see a pod. Exceptions, however, should be made—that of the Duke of Northumber-

in the greatest abundance. The disc is brown, the ray-florets are yellow, with large velvety-brown spots at the base—a colouring which may be compared to that of *Obeliscaria pulcherrima*, or that of the dwarf French Marigold "*Legion of Honour*."

MR. F. C. HEINEMANN, ERFURT, CATALOGUES THE FOLLOWING—

Heinemann's New Emperor Salpiglossis.—It forms only one single leading stem, which often grows as thick as a finger, and bears on its end a bouquet of the most beautiful flowers. Every one of them is richly veined with gold, and considerably larger than those of the old "*grandiflora*" type. The throat is wide open and short. The edge of the flower is not so deeply incurved as with the old variety, which gives it a more round shape.

Sky blue, pillar shaped Forget-me-not.—A *Myosotis* striking by its very unique structure. All branches that form the plant grow perpendicularly. By this compact growth every plant forms a regular pillar or column. This habit makes the variety particularly useful as a pot plant for market sale, or as edging for flower-beds and any other decorative purpose. There are new varieties of *Gloxinia*, *Pansy*, crested *Begonia*, &c.

HORTICULTURAL EDUCATION.

WE have sought, says Professor BAILEY, in a recent *Bulletin*, not so much for new facts as for some way of driving home the old facts. We have tried to set forces at work which would silently extend themselves when we had left them. Fortunately, we have been greatly aided by the hard times and the multitudes of bugs and special difficulties. These things have driven people to thinking and to asking for information. The agricultural communities are thoroughly aroused, and now is the time to teach. When one is thoroughly prosperous in his business, there is little chance—as, in fact, there is generally little need—of teaching other methods. The efforts to reach the people, in the progress of our work, may be classified under five general heads. These efforts have all been experiments in methods of extension teaching as applied to horticulture. We have tried to ascertain the value of: (1.) The itinerant or local experiment as a means of teaching; (2.) The readable expository bulletin; (3.) The itinerant horticultural school; (4.) Elementary instruction in the rural school; (5.) Instruction by means of correspondence and reading courses. In the local experimental work, something over 100 different experiments have been planned and prosecuted in different parts of western New York. These comprise experiments in tilling the land, in pruning trees, in fertilising the soil, spraying, combating insects and fungi, and the like. The fundamental purpose in these experiments is to teach by means of object lessons and not to collect scientific facts, although the latter often come as a very valuable incidental result. The horticultural schools have been about forty in number. These are meetings which last two or more days, at which time certain instructors take up definite lines of instruction, giving by far the greater part of their attention to underlying principles and not to mere facts or methods. The fundamental difficulty with our agricultural condition is that there is no attempt to instruct the children in matters which will awaken an interest in country life. We have therefore conceived that the place in which to begin to correct the agricultural status is with the children and the rural schools. For the purpose of determining just how much could be expected from this source, many rural and village schools were visited during the past year, the instructors talking to the children about any object which presented itself at the time. The result was that all the instructors were impressed with the readiness with which the children assimilated the information, their keen desire for it and a notion of it, and the almost universal impression that teachers took in this kind of work. We are convinced that the greatest good has been rendered to the agricultural community by awakening an interest in nature-study in the teachers and children.

THE ONION CROP OF 1897.

THE Onion crop of 1897 in the United States is far short of a full one, and materially smaller than that of 1896, which in turn showed a considerable deficiency.

Exhaustive investigations recently made by our contemporary the *American Agriculturist*, in every important Onion growing section of that country showed the commercial crop of 1897 to be 2,300,000 bushels, compared with what may be called a full yield of 3,000,000 bushels, that figure being reached in some recent years. The crop now being secured and marketed, has turned out rather better than seemed possible a month and more ago, yet it is by no means a large one.

In some of the most important sections of the Onion belt, it is little more than half a yield, but this is partially offset elsewhere by increased acreage and good crops. The high prices last winter and early spring stimulated the acreage for the present crop.

The Onions secured excellent early growth as a rule, and progressed well until midsummer, when weather conditions turned unfavourable, checking development which was never fully recovered. This was notably the case in the Connecticut valley, in Orange county, and Central New York, and in parts of Ohio, the West being less disturbed, and yielding fairly well from the scattered acreage.

The acreage, finally harvested, does not differ much from that of 1893, in spite of the tendency last spring to increase the area under the Onion crop. A good many fields which originally had a fair start, later deteriorated so rapidly that growers abandoned them or put the land into other crops. As a result, the acreage finally harvested was considerably less than at one time seemed probable. As a whole, the rate of yield per acre was smaller than last year. Occasional sections where weather conditions were favourable, and extra care given the crop in the way of fertilisation, cultivation, &c., show a very good rate of yield; some areas give 500 to 600 bushels to the acre as lifted, yet when the Onions are weighed out this figure will be greatly reduced, bringing down the aggregate commercial crop considerably; the latest returns show that as a rule the Onions of 1897 possess excellent keeping qualities.

Comparing the opening of the season with that of last year, prices paid to growers in the country show thirty to fifty per cent. advance—this fact is nearly universal.

The undertone in the Onion market for choice grades is one of decided firmness. *J. J. Willis, Harpenden.*

THE WEEK'S WORK.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maidenhead.

Clearing and Re-planting Flower-beds.—The summer bedders being now mostly flowerless should be cleared away, and more especially those in beds which have to be re-planted with others for winter and spring decoration. As fast as the plants are cleared off, the beds should be deeply dug over, and if thought to be necessary, a small quantity of decayed manure incorporated with the soil. At the time of writing, the earth in some of our beds is so dry that a soaking of water is necessary before re-planting, a very unusual thing at this date. Large beds, or those which occupy the middle area in flower-gardens of considerable dimensions, have a pleasing effect if thinly planted with small *Retinosporas*, such as those known in gardens as *R. pisifera*, *R. p. var. aurea*, *R. plumosa var. aurea*, *R. p. var. argentea*, *R. ericoides*, *R. squarrosa*, and the forms of *Cupressus Lawsoniana* in variety. The bed or beds so planted may be edged with a broad band of *Violas* or other dwarf-flowering plants mentioned below, and a ground-work of the same added where the *Conifers* are very sparingly employed in the beds. There are many other kinds of shrubs that are admissible in these winter beds, such as small plants of *Rhododendron hybridum*, well set out.

Andromeda floribunda and *A. variegata*; *Mahonia aquifolia*, *M. laurels*, *Phillyrea angustifolia*, which, if kept in small masses, may be continued in flower.

They may be continued in flower.

patches of distinct colours, as the Blood Red, I rose Dame, Belvoir Castle, yellow, look better mixtures. Other subjects for the spring garden *Violas*—these especially, and *Pansies*, *Myosotis*, *stiflora* and *M. alpestris Victoria*, *Daisies*, *Po* these, *Aubrietias*, especially high-coloured varieties like *Leichtlini*; *Silene pendula*, rose-coloured, *S. alba*, and *Saponaria ocymoides*, should not be ready for being set out as strong plants. They being of dwarf stature, are well suited for narrow or small beds, in conjunction with *Narcissus*, *Hyacinths*, *Squills*, *Tulips*, &c. *Saponaria* being in flowering, should, if possible, be afforded a position where it will not be necessary to clear the place away whilst still in their flush of beauty.

Hyacinths are trustworthy spring-flowering plants and should now be got quickly into the ground, large masses of colour are desired, beds may be thickly with bulbs at 6 to 8 inches asunder. These the soil of the beds, after digging, should be raked down and trodden moderately firm, and heavy, a good dressing of coarse sand should be raked into the surface to go in with the bulbs. In planting the bulbs, a blunt-ended dibber with a bar to regulate the depth of the hole, is the hand tool to use. The bulbs should be put with the point quite 4 inches deep. The most pleasing arrangement, however, is to associate *Hyacinths* with *Pansies*, *Violas*, *Myosotis*, &c., as then the beds have a better furnished appearance during the winter, and the display is continued after the bulbs are over. When this method of planting is practised, the ground plants should first be got in, and the bulbs put about 10 inches apart between them.

Tulips.—These should be planted forthwith. Remarks on mixtures applied to *Hyacinths* also apply here, although beds filled entirely with *Tulips* at 4 to 6 inches apart are very effective when of large size. When used in mixture with *Pansies*, *Violas*, *Aubrietias*, &c., we have pleasing contrast and a long season of display. The *Van Thol* seed are the earliest to bloom, and are also dwarf, they may be planted thicker than the larger-flowered varieties. *Canary Bird*, *Kaiser Kroon*, *Proserpine*, *Joost Van Vondel*, *Purple Crown*, *Duke of York* and *Prince of Austria*, are good varieties for beds, the two last being the latest to flower.

Other species of Bulbs.—*Daffodils* in variety are much used for spring bedding, namely, *Sir Walter* and those of the bicolor section, as *Horseshoe*, *Emperor*, and *Empress* are bold and free-flowered varieties, but the selection may be infinitely varied. *Snowdrops*, *Crocuses*, and *Scillas* should be planted thickly near the margins of beds and borders, and the early-flowering *Erythronium Dens Canis* is an effective plant in similar positions, its handsome foliage being an additional point in its favour. The roots of tuberous *Anemones* should be in the ground this month, giving them, if possible, a position where they may remain undisturbed for some years.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Birkford, Dorking.

Orchids now in Flower.—A few years ago *Orchids* were very scarce during the autumn months but the following list of plants now in flower will show that an advance has been made:—*Cattleya labiata*, *C. aurea*, *C. Bowringiana*, *C. Lord Radcliff*, *C. Mantini*, *C. Wendlandiana*, *C. bicolor*, *Laelio-Cattleya albanensis*, *Laelia Perrini*, *L. P. nivalis*, *L. P. alba*, *L. pumila*, *Dendrobium Phalaenopsis*, *Dearei*, *D. sanguinolentum*, *D. chrysanthum*, *Pleuro maculata*, *P. lagenaria*, *P. Wallichiana*, *Catasetus*, *Bungerthii*, *C. longifolium*, *Pilumna fragrans*, *Oidium aurosum*, *O. obryzatum*, *Vanda Kimballii*, *Habenaria militaris*, *H. carnea*, *H. c. nivalis*, *C. thum*, *C. Lawrebel*, *C. concolor*, *C. barba bellum*, *C. Sedeni*, *C. cardinale*, *C. purpureum*, *C. insignis*, *Sanderia*, *Paphia cristata*, *Zygopetalum maxillare*, and *Masdevallia macrura*. Some plants of *Cattleya Bowringiana* are already producing clusters of young roots from the base of the new made pseudo-bulbs, and such plants that require potting, although in bloom, should be attended to once. If repotting be delayed until the flowers be faded, the points of the new roots may be injured. *C. labiata*, too, should be repotted immediately the roots are observable. When *C. aurea* has passed the flower, keep the plants on the dry side until root action commences, and then afford fresh rooting material. The same remarks apply also to the other hybrids mentioned. Repot *Laelia Perrini* and other varieties immediately they have flowered. *Zygopetalum maxillare* thrives best if secured to a post.

of Tree Fern stem, and kept in a warm corner of the Odontoglossum-house, never allowing the plant to become the least dry at the root. *Dendrobium Phalaenopsis* requires a light position in the East Indian-house, and after the spikes of flower have been cut, water at the roots should be withheld. The same position will suit them when at rest, and their immediate surroundings should be kept quite dry. *D. Dearei* and the rich-coloured *D. sanguinolentum*, although in flower, are developing new growths. Suspend the plants on the shady side of the hottest house, and afford copious waterings each time the compost appears dry. *D. chrysanthum* suspended to the roof of the intermediate-house, should be kept perfectly dry at the root until growth recommences. *Pilumna fragrans* is best in the cool-house, and should be watered with care. *Oncidium obryzatum* also thrives best with the *Odontoglossums*. *O. aurosum* may be removed to the intermediate-house immediately cold weather occurs.

Vandas.—The present is the best season of the year to look to the roots of *Vandas* of the tricolor and *suavis* section. The plants do not like strong sunlight, and now that the sun is daily decreasing in strength, and the external air is cool and moist, a suitable atmosphere can easily be maintained in the house. This is a great help towards the re-establishment of the plants without loss of foliage. To re-pot them now is also favourable to the production of fresh roots. The old roots that will be buried in the new compost will quickly make numerous laterals, and they have plenty of time to become thoroughly well rooted before they have to withstand the heat of summer. It is principally those plants that have lost a number of their lowermost leaves that will need attention. In removing the plants from their pots, take care not to break or crack the large succulent roots unnecessarily. Shake the old compost away, and cut the bottom of the stem off so far as to allow the lower leaves, when the plant is transferred to the new pot, to be just on a level with the rim. Place the plant in its proper position, and make the drainage secure with a few pieces of crock, and over these a layer of sphagnum. Spread out the lower most roots carefully, and work in amongst them and the remaining roots some clean-picked sphagnum-moss, intermixing with this plenty of broken crocks. Fill up to the rim of the pot, and surface the whole with fresh healthy sphagnum. Press the materials down firmly, and tie each stem to a strong stick, to hold the plant in its proper position; this is important, as any swaying about will cause the lower leaves to turn yellow and fall off. Plants that are well furnished with leaves down to the rim of the pot should not be disturbed; but if the sphagnum-moss has become sour and decomposed, it may be removed, and fresh moss substituted. Following root-disturbance, no water should be afforded for several days; then the plants may be watered thoroughly, which will be sufficient to keep the moss damp for a considerable length of time. Each time the moss on the surface becomes dry, it may be sprinkled over to keep it alive. Give the plants a cool intermediate temperature, keep their surroundings moist at all times, and shade from strong sunshine, especially after repotting.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Ledbury.

Peaches and Nectarines.—If fruits are required early in May, trees should be forthwith got in readiness for starting; to force in the first week of November, and to have fruit to come in at the end of May, or the commencement of June, starting may be delayed till December 1, or a fortnight later than that date if the trees have been often forced. Getting in readiness means, that the trees be unfurnished from the trellises and pruned, then cleaned with Gishurst's compound, to which a small quantity of strong tobacco-water is added, using it at the full strength recommended by the makers, and applying it with a scrubbing-brush for the hard branches and shoots; and with a paint-brush, and at half-strength, for the soft, young shoots. See that the old ties are removed and burnt; be sure that the mixture is well rubbed in, and that no branches or shoots are missed by the operator. It is a very good plan, if the trees have been badly infested with black aphid or brown scale, to wash the trees twice, it being a saving of labour at a later date to make sure that the trees are quite clean now. As soon as the trees have got dry, they may be trained anew to the trellises, using tarred string or withes in securing the largest branches, and raffia for the weaker shoots; or, in case the trees are secured to a wall, make use of clean shreds and nails or studs and raffia. Be

careful to allow sufficient slackness in each tie, to permit full development of the shoots without constricting the rind, and to distribute the bearing-wood regularly; and leave a few young shoots to fasten over bare branches, thereby covering the latter with foliage, and improving the appearance of the trees, as well as affording protection from the sun, the lack of which is sometimes the cause of loss of branches. As soon as the trees are trained, let the border be cleaned up, and if the uppercrust is found to be sodden, or it has been much trampled upon, fork it up lightly, removing some of it, and affording a dressing of heavy loam and lime-rubble; but if the trees have been root-pruned, this will not be necessary, and a pointing of the surface where it is trodden down will suffice. Finally afford a slight mulch of long stable-litter, and lime-wash the walls. When the trees are started, afford the border a thorough application of tepid water, and close the house. At the commencement a temperature at night of 40° to 45°, 5° higher doing no harm if the outside temperature is high; by day 50° to 55° will suffice. Sprinkle the trees in the morning, and again at half-past 2 p.m. At this season progress is slow, but there is no need to hurry the trees—in fact, to do so will defeat the end in view; but the trees may be pushed on rapidly when the days are lengthening.

Later Peaches containing trees whose foliage still hangs on them should be kept well ventilated, the leaves being partially removed by drawing the hand lightly upwards, or a new birchbroom or housemaid's handbrush may be employed in the direction that the shoots run.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Winter protection.—It should be the aim of everyone in charge of a garden, be it large or small, to provide plenty of protective material during the autumn months, and to have it in readiness for use whenever it may be required to protect plants from frost. Bracken if cut early when ripe, and dried, and then stored in a shed, or made into a stack and thatched with straw, is of great use for this purpose. Bows of Hazel or Ash may be placed over the rows of Parsley to support garden mats, or light hurdles thatched with straw used instead. A good thick layer of coal-ashes should be spread over the crowns of Parsnips, Seakale, &c., in order to keep frost out of the soil, and allow roots to be lifted when required. This form of protection is a capital one for the preservation of the stools of Globe Artichoke during the winter. It should be placed cone-like round each plant, one barrow load being sufficient to cover one stool.

Herbs.—The border should now be cleaned up and put in order for the winter; beds of Mint, Tarragon, and such like herbaceous subjects should be weeded, decayed shoots removed, and a liberal dressing of short manure applied. New beds on a fresh site may now be made on fairly rich soil; or if the land be poor, some decayed manure may be dug into it when planting the roots. Place the roots thinly in fairly deep drills drawn 1 foot apart, and put a mulch of short manure over all as a finish. If the roots are not taken up for re-planting, it will still be necessary to chop round the outside of the clumps of Tarragon, Mint, and Marjoram, and fork out all straggling roots from alleys, and by the side of paths, the roots spreading so much generally as to become a nuisance if let alone. Shrubby herbs, as Thyme, Sage, Hyssop, Horseround, Winter Savory, &c., may have a dressing of short manure lightly forked in between the rows if to be left on the same site; but it is a good plan to re-plant these at the least once in three years, or the beds may become patchy, and the plants die out entirely, being smothered by their stronger neighbours.

Leeks.—Although Leeks are accommodating, and the hardest of winter vegetables, they require attention if blanched stems of a good length are required, and failing which, they are only of use for flavouring purposes. For this purpose it is customary to plant in trenches, and treat the plants similarly to Celery; but for kitchen use, stems 8 inches are long enough, and these are secured with less labour. If the Leeks were planted as advised, namely, in deep drills, that would be ultimately levelled by the hoe in killing weeds, the plants may now be earthed-up by simply drawing the soil up to them if they are planted sufficiently wide apart to admit of this being done; but if thickly planted, the desired blanching may be ensured by placing leaf-mould, cocoa-nut fibre, or coal-ashes, between the rows, care being taken not to break the leaves in doing this.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton Hoe Park, Luton.

Bouvardias.—Plants which have been flowering since September should be afforded weak liquid manure-water, and if they have a stunted appearance, a sprinkling of Clay's or other safe artificial manure may likewise be given in addition. Let them be exposed to full sunshine, and the temperature of the house be kept at about 55° at night, and 60° by day. The spring-struck *Bouvardia*, which will form the next lot of flowering plants, should be copiously syringed until the first flowers have opened, when it must be discontinued. Desirable varieties are the following:—President Cleveland, flowers coloured scarlet; Mrs. Robert Green, and Priory Beauty, with pink flowers; and Vreelandi, with white ones, are good for flowering till late in the winter.

Souvenir de la Malmaison Carnations.—The house or pit in which these plants are grown may be, for safety's sake, fumigated with tobacco, or vaporised with XL All for the destruction of aphides at fortnightly intervals. Afford air abundantly excepting in very moist or foggy weather, and warm the hot-water pipes somewhat at such times and admit only a small amount of air. The plants will now require great care in affording water, and it is safer to err on the dry, than the wet side through the next three months.

Euphorbia Jacquiniflora and E. (Poinsettia) pulcherrima.—These plants thrive at this season if the warmth is maintained at 65° by day, and 60° by night, affording liquid manure-water liberally if they are pot-bound. The plants may be syringed on fine days, the house being closed early; but after colour appears in the bracts, syringing should cease, damping between the pots mornings and afternoons being done instead.

Zonal Pdaragoniums.—These plants should be afforded warmth of 50° at night, with a slight rise of say 8° to 10° by day, to such as are flowering, and an occasional application of clear soot water. Let the pots be washed and kept quite clean, and the decaying flowers removed.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Wintering Pot-Strawberries.—Many ways of wintering pot-Strawberry plants are recommended and practised, but, in my experience, the most natural, simple, and effective method of doing this is to plunge the pots below the rims in sifted coal-ashes, sawdust or leaf-mould. It is necessary that the site selected be high enough to prevent water accumulating about the pots at any time, and the aspect should be south or west. For many years I wintered pot-Strawberries in improvised frames (without covers) in which I used to grow my Wallflowers for transplanting to the flower-beds in October, and to harden off summer bedding-plants in the spring. These frames were about 7 feet wide, of varying length, and consisted of two 6-inch boards—sides and ends—secured to pointed wooden stumps driven into the ground at about 4 feet apart. Such frames are easily made, and they have a tidy appearance. The bottom, too, was hard, and the situation dry. The pots should be stood closely together on coal-ashes, so as to keep worms out of the pots, the plunging material being firmly packed in between the pots and carried above the rims to the thickness of about 1 inch. This covering will save the pots from being cracked by frost. Thus wintered I always obtained satisfactory results from my forcing Strawberry plants. It is unnatural as well as injurious to Strawberry plants to subject them to the "drying-off" process during the winter months, as is actually done by stacking the pots on their sides in rows, two or three thick in the open; and in pits and frames, seeing that the plants growing under natural conditions out of doors are never dry at the roots during the winter and spring.

Plantations of Strawberries should be hand-weeded, and after that is done, the land should be coated with short, decayed manure to the thickness of about 3 inches.

Raspberries.—Remove the superfluous canes of the current year's growth carefully from between the rows of fruiting-canecan, laying them in by the heels, for forming new plantations, and filling up vacancies. If the land be dry when new plantations are made, the plants should receive a heavy application of water, in order to settle the earth about the roots; and after the holes are filled in, and the surface made level, a mulching of half-rotten dung may be placed along the rows.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR NOVEMBER.

TUESDAY,	Nov. 2	Chrysanthemum Shows at Croydon, Plymouth, Devizes, Brighton, and Stratford-on-Avon.
WEDNESDAY,	Nov. 3	Chrysanthemum Shows at Ealing, Blackheath, Sunningdale, Lowestoft, Cardiff, Woking, Southampton, Wolverhampton, Isle of Thanet, Teignmouth, North Peckham, and Royal Horticultural Society of Ireland.
THURSDAY,	Nov. 4	Chrysanthemum Shows at Highgate and Exeter.
FRIDAY,	Nov. 5	Altrincham, Bowden, Sale and District Chrysanthemum Soc.
SATURDAY,	Nov. 6	Soc. Franc. d'Hort. London. Isle of Wight Hort. Assoc. meet.
TUESDAY,	Nov. 9	Royal Hort. Soc. Coms. National Chrysanthemum Society's Show at Aquarium (three days). Chrysanthemum Shows also at Kingston, Birmingham, Leeds, Croydon and Farnham.
WEDNESDAY,	Nov. 10	Chrysanthemum Shows at Liverpool, Eastbourne, Carlisle, Hanley (Staffs.), and Brixton. Harrison & Son's Annual Exhibition of Vegetables and Farm Roots, at Leicester.
THURSDAY,	Nov. 11	Chrysanthemum Shows at Putney, Hammersmith, Winchester, and Spalding.
FRIDAY,	Nov. 12	Chrysanthemum Shows at Sheffield, Wilmslow, Windsor, and Bradford.
TUESDAY,	Nov. 16	Chrysanthemum Shows at Belfast, Chester, Ipswich.
WEDNESDAY,	Nov. 17	Chrysanthemum Shows at Hull, York, South Shields, Reading, Buxton, Bristol.
THURSDAY,	Nov. 18	Scottish Horticultural Society's Chrysanthemum Show at Edinburgh (3 days).
FRIDAY,	Nov. 19	Chrysanthemum Shows at Huddersfield and Stockport.
TUESDAY,	Nov. 23	Royal Horticultural Society's Committees.

SALES FOR THE ENSUING WEEK.

MONDAY,	Nov. 1	Dutch Bulbs, at Protheroe & Morris' Rooms. Bulbs and Plants at Mr. Stevens' Rooms.
TUESDAY,	Nov. 2	Dutch Bulbs, at Protheroe & Morris' Rooms. Annual two days' sale of Immense quantities of nursery stock at the Hale Farm Nurseries, Tottenham, by order of Mr. T. S. Ware, by Protheroe & Morris (two days).
WEDNESDAY,	Nov. 3	Bulbs, Plants, Roses, Fruit Trees, Shrubs, &c., at Mr. Stevens' Rooms. Dutch Bulbs, at Protheroe & Morris' Rooms.
THURSDAY,	Nov. 4	Bulbs and Plants, at Mr. Stevens' Rooms. Dutch Bulbs at Protheroe & Morris. Sale of well-grown Nursery Stock at the Burnt Ash Hill Nurseries, Lee, by order of Messrs. B. Malter & Sons, by Protheroe & Morris.
FRIDAY,	Nov. 5	Dutch Bulbs and Orchids at Protheroe & Morris' Rooms.
SATURDAY,	Nov. 6	Bulbs and Plants at Mr. Stevens' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—45° 1'.

ACTUAL TEMPERATURES:—

LONDON.—October 27: Max., 58°; Min., 46°.

PROVINCES.—October 27 (6 P.M.): Max., 58°, Scilly; Min., 45°, Ardrossan.

Weather generally dull; foggy, mild.

The Victoria Medal of Honour. It has often been made a subject of complaint that gardeners receive no public or official recognition. Whether they are worse off in this respect than the members of other professions

may be doubted; still, the complaint shows the necessity that is felt in this country for establishing an "Order of Merit" for other than political services and financial success. What sort of honour is it that is conferred on a professional man, an artist, a man of science, when he is associated with men whose only claim to distinction is measured by their services to their political party or municipality, or by the balance at their bankers? What honour did TENNYSON derive, in public estimation, from admission to the House of Peers? Can we suppose that a NEWTON, a DARWIN, an OWEN, a HUXLEY, a LINDLEY would have been more honoured by being made Peers? And yet such men were clearly deserving of the highest honour that could be paid them, and being human, they would not have been averse from accepting it. The point is, that the honour should be a fitting one. The honours conferred on military and naval men, and on civil servants of the Crown, are usually appropriate enough, but the comparatively few official compliments bestowed outside the "services" are often incongruous, and suggestive of ridicule rather than of respect. This arises partly from the mixed company to which the honoured one is ushered, partly from the fact that the compliment is conveyed through ministers or others who can have nothing but a hearsay acquaintance with the merits of the recipient.

It is otherwise when the honour comes from, or at least is suggested by, a man's associates, who have the opportunity of knowing and of judging the value of their colleagues' labours. From this point of view the Victoria Medal of Honour, instituted with the QUEEN'S consent, by the Royal Horticultural Society, is peculiarly valuable. The Council of the Society, as we have reason to know, sought, in confidence, the opinion of numerous representative men in various parts of the country as to who would be suitable recipients of the Medal.

Having such a mass of opinion before them, it then became the duty of the Council to proceed to the very difficult and delicate task of selecting the sixty. The final selection is by no means ideally perfect; but, at least, it has been arrived at after anxious care and strict impartiality. We are proud to think a hundred more equally worthy (with one or two exceptions) could easily have been found, hence those on whom the honour was conferred will, of course, look on themselves in the light of representatives of others. It is difficult to see how, on the whole, the selection could have been better made, and it is equally difficult to see how the list could have been improved when many of those who, by universal verdict, would have found a place therein, felt themselves debarred, from one cause or another, from being nominated.

In any case, high festival was held at the Royal Horticultural Society on Tuesday last. The occasion was unique. It is likely to remain so. The warm applause with which the recipients of the medals were greeted showed conclusively that the movement had the sympathy of the audience. We can but congratulate the Society on the success of this novel and hazardous venture; and we felicitate those of our friends and colleagues who have so richly merited the compliment made to them.

Every effort should now be made to jealously maintain and enhance the honour; hence it may be desirable to add that the use of the honour for advertising or other commercial purposes is entirely opposed to the whole spirit of the scheme, and should be sternly deprecated.

There are happily some things which cannot be estimated by a monetary standard, and this is one of them.

The medal itself is an elegant and artistic production, a trifle larger than a shilling, the work of Miss MARGARET GILES, and is much admired by connoisseurs. We are a little puzzled to know which is the obverse and which the reverse, and we think that space should somewhere have been found for the addition of the recipient's name. Perhaps even now the rim of the medal may not be found too narrow to make this addition, failing which a diploma of some sort should also be sent to the medallists recording the fact of the award.

One other point—the council, as we think judiciously, declined to allow their own names to be put forward, though there are several of its members amply deserving of the compliment. Probably an opportunity will occur hereafter of adding their names as vacancies occur.

But what applies to the council, does not apply to the Secretary and Treasurer, still less to the President. In our opinion these gentlemen, and most particularly the President, should be Victoria medallists by virtue of their office. This is an omission that can be rectified at the next annual meeting. As it is, the medallists constitute a body without a head.

A detailed account of the very interesting proceedings on Tuesday last will be found in another column.

THE DUCHESS OF TECK.—The Duchess was so well known to horticulturists as an ardent lover of flowers, that the announcement of her death will be received with great regret. Residents at Kew, and more recently those at Richmond, as well as frequenters of the "Botanic" will miss her, and many a charitable institution will be the poorer, and the weaker by her decease. To a former generation, as Princess MARY, she was endeared by her geniality and willingness to aid in all works of good fellowship and charity. To her was dedicated Messrs. MOORE & JACKMAN'S volume on the Clematis, so that her name will be associated with one of the most remarkable triumphs of Horticulture.

SOLANUM CORNUTUM.—Many of the best of the "sub-tropical" species of Solanum are exhibited every summer in the Cambridge Botanic Garden, and among them *S. cornutum*, the subject of the illustration (fig. 94), is remarkable, not only for its beautiful foliage, but also for its effective golden-yellow flowers. Unlike the majority of these Solanums, it appears to be strictly annual, and while some others, to produce the finest effect, must be sown some time during the preceding year, this can be sown with other annuals in spring. It may even do fairly well if sown in the open, under favourable conditions; but the only safe plan is to sow in gentle heat during March, and plant out from large 60's, or preferably 48-pots, early in June. The flowers are so beautiful, and the leaves so handsome, that it is well worth all this trouble. It provides a good bed or group, and few would say they had ever seen the plant before. As grown at Cambridge, it reaches a height of from 18 inches to 2 feet. The stems are branching, comparatively slender, green, and covered with slender spines, as are all parts of the plant, in greater or less degree, up to the corolla. The leaves are light green, about 4 inches long, and divided in a manner which is better understood from the illustration than from any description. The flowers are produced in raceme-like cymes to the number of nine or a dozen, and are rather more than an inch in diameter. They are produced in succession, and one or two only are open at a time, but the cymes are very numerous, no good leaf failing to have one belonging to it. As the flowers wither, numerous small fruits, covered with numberless

slender spines, are formed, and these fruits form a very distinctive and attractive feature. This plant has been grown for the nearly allied *S. Fontanesianum*, and seeds under that name were received from Messrs. HAAGE & SCHMIDT, but by Kew determination it proves to be *S. cornutum*. Its native country is Mexico [see JACQUIN'S *Ecloga*, t. 104]. *R. Irwin Lynch, Cambridge Botanic Garden.*

LINNEAN SOCIETY.—The first meeting of the Society for the forthcoming session will be held on Thursday, November 4, at 8 o'clock, P.M., when the following papers will be read:—The Right Hon. Sir JOHN LUBBOCK, Bart., M.P., F.R.S., "On the Attrac-

house & Sons, and Messrs. Geo. Bunyard & Co., Maidstone. A paper on "Hardy Fruits, their Cultivation and Improvement," read by the Rev. Gordon Salmon, was listened to with much interest.

JAPANESE TUSSILAGO.—The *Moniteur d'Horticulture* gives an account of these plants. The scented Tussilago (*T. fragrans*) bears flowers white, red, and shading into rose, diffusing a sweet scent as of Heliotrope, and is sometimes called Winter Heliotrope. Hitherto *Petasites*, a name which is connected with parasol, has been looked upon as an ornamental plant only, but now MM. CROUX & FILS of Aulnay (Seine) have introduced

October 20, Colonel HALFORD THOMPSON, the patentee and chairman of directors, presiding. The directors' report was of a very satisfactory character, the year's trading having severely taxed the manufacturing capacity of the present plant, and made it almost imperative that the premises be enlarged, to cope with the fast increasing demand. They recommended a dividend of 10 per cent. on the paid-up capital. The Chairman, in moving the adoption of the report, spoke of the highly favourable reports which had been received from the Vine-growing districts of France—Charente, Cognac, &c.; of the success of Jadoo in Tobacco-growing in Pennsylvania, Orange trees in the West Indies, general horticulture

FIG. 94.—*SOLANUM CORNUTUM*: FLOWERS YELLOW. (SEE P. 310.)

tion of Flowers for Insects." Mr. W. C. WORADELL, "On Transfusion-tissue, its origin and function in the leaves of Gymnospermous Plants" (communicated by Dr. D. H. SCOTT, F.R.S., F.L.S.). Exhibitions—Mr. F. G. JACKSON: Some Zoological and Botanical Exhibits, collected by the Jackson-Harmsworth Polar Expedition. Mr. REGINALD LODGE: Lantern-slides of Marsh-birds and their nests, from photographs recently taken in Spain and Holland.

THE ANCIENT SOCIETY OF YORK FLORISTS met on the 22nd inst., when a very fine exhibition of hardy fruits was made, including collections from the Archbishop of York, Lord Hotham, Lady Decies, Dr. Hingston, Rev. Gordon Salmon, Messrs. Back-

from Japan a new giant variety, which is useful as well as decorative. It is edible, the petioles can be utilised much as is Rhubarb, and the flower-buds can be pickled in vinegar. But the chief value of these *Petasites japonicus giganteus* appears to be in rain or sunshade. Surprised by these, it is only necessary to gather a leaf of this Composite, and immediately you have a sunshade or umbrella, with a handle or leaf-stalk 6 feet long, and at the end a large rounded leaf, forming a shelter from sun or rain! A quaint little Japanese sketch gives a presumably correct idea of the leaves when used thus.

JADOO, LIMITED.—The second ordinary general meeting of this company was held at Exeter on

in Natal and other parts of South Africa, in India, Australia, and pretty well all over the world. It is probable that manufacturing branch depôts will be set up in Natal, Philadelphia, France, and other distributing centres where Jadoo is becoming well known and in great demand. The Chairman pointed out that this new material might still be considered as being in an experimental stage, but that experiments and results so far indicated that the company was well on the road to be a great success. The accounts showed the total liabilities of the company to be £8189 2s. 4d., including a sum of £630 14s. 5d. carried to the appropriation account. The assets were: By debtors, £1763 5s. 10d.; stock, £1164 1s. 1d.; building, plant, machinery, &c., £590 16s. 3d.; patent rights,

trade-marks, &c., £2935 8s. 11d.; French agency, £144 4s. 3d.; cash in bank, £1588 8s. 9d.; in hand, £2 17s. 3d. The accounts were audited by Mr. P. J. LIDDELL, Incorporated accountant.

DAHLIA, KEYNES' WHITE, IN GERMANY.—Quite recently, two of the leading horticultural societies in Germany, the Verband der Handelsgärtner Deutschlands and the Verein der Kunst- und Handelsgärtner, Berlin, have in each case unanimously awarded a certificate (Werthzeugnisse) to this new Cactus Dahlia, raised by Messrs. KEYNES, WILLIAMS & Co., of Salisbury, and which they intend to send out for the first time next spring.

CATTLEYA LABIATA.—The first exhibition of flowering specimens of this beautiful Orchid will be held at 79, Rue Wierz, Brussels, from the 7th—9th of next month. A very fine exhibition is anticipated. There will be no competitive groups, but prizes of various kinds will be allotted by the jury to deserving exhibits.

PLANTS IN THE HOUSES OF M. EM. BEDINGHAUS.—M. BEDINGHAUS' plants (at Wondelgem, Ghent), coming from Japan, Chili, the Cape, New Holland, Van Diemen's Land, New Zealand, and other countries form a most interesting collection. Wondelgem is known in the horticultural world through the large establishment there owned by M. DE GHELLINCK DE WALLE. M. BEDINGHAUS' specimens are all well cultivated, and richly repay a visit even when not in bloom. I noticed on my visit in early October, thirty varieties of indigenous Ivies from Russia, Algeria, Ireland, Japan, &c., of which the most curious is *Hedera helix conglomerata*. There are also *Smilax maculata*, *Agave salmiana*, *Euonymus radicans* fol. var. grafted on *Euonymus japonica*, and making a pretty standard; a large specimen of *Genista Andréana*; one of *Erica arborea*, 6 feet high by about 12 feet round; and *Acacia grandis* from Western Australia. *Tremanda verticillata* is certainly a fine flowering plant; *Sollya heterophylla*, a Pittosporaceae plant, is an old favourite; *Lapageria rosea* and *alba*, grow here in a conservatory facing the mid-day sun, and flower well. I also noted *Cuphea Llavea*, D.C., introduced from Mexico in 1829; the old *Fuchsia pulchella*, *Cuphea eminens*, or rather *C. jorullensis*, also from Mexico. *Phygelius capensis* is an interesting plant, which, like *Pentstemon*s, should be more widely cultivated. In the open air, and very healthy, are *Thea Bohea*, *Veronica diosmaefolia* and *buxifolia*, pretty specimens; and *Acacia platyptera*, very peculiar. *Correa flava* is also an old plant, *Boronia viminea* major and minor, and *Bauera rubioides*, introduced from New South Wales in 1793, also grow here. Among the finest *Acacias* are *A. lineata*, *pendula*, *Drummondii*, *verticillata*, and *paradoxa*; *Adenandra fragrans* from the Cape, and *Escallonia macrantha* from Chili; the former known since 1812, the latter since 1848, deserve notice, as does also *Diosma ericoides*, introduced from South Africa in 1756. Here are also *Eutaxia myrtifolia*, cultivated, like a *Chorizema*, *Eleagnus reflexa* fol. var., 13 feet round; a very large *Brachysema acuminatum*, *Chorizema splendens*, *Metrosideros*, *Araujia sericifera*, a curious Brazilian *Asclepiad*, *Kennedya purpurea*, *Pultenaea striata*, and *Illicium religiosum* or *I. anisatum*. This brief list will give some little idea of M. BEDINGHAUS' treasures. *Ch. De B.*

A NEW USE FOR RAFFIA.—Raffia does not, at first sight, appear likely to meet with the approval of ladies who excel in fancy work, but that it may be thus turned to account—and to very good account, too—has lately been seen. Some curtains that we saw a few weeks ago in one of the quaint streets of the old French town of Laon, claimed our attention as a novelty, and it was with some surprise that we found that Raffia was the material used for their manufacture. They consisted of a number of rosettes made, as we were told, by an expert with a crochet-hook and a gigantic hairpin, known to ladies as a fourché hook, or fork, and were finished with a border fashioned with the same tools. For windows, whence it is necessary to hide the outlook,

for porches, verandahs, summer-houses, and conservatories, such curtains would be likely to prove both useful and durable. No doubt the idea could be improved upon, and there would be little difficulty, probably, in dyeing the bast were its natural biscuit colour not considered sufficiently ornamental.

FORCED STRAWBERRIES.—Some of the points in the cultivation of Strawberries under glass which appeal to us with special force are these:—1. Very strong plants to begin with, which have been kept in vigorous growth, and not allowed to become pot-bound until they have reached 6-inch pots. 2. Varieties which are early, or at least not later than mid-season; and preferably those which themselves produce an abundance of pollen. 3. The exercise of great care to have the plants free of fungous diseases and insects before they are put upon the benches. 4. The devoting of an entire house to the crop. If two or three different crops are grown in the same house, none of them can receive the very best treatment which they demand; and if there are other plants in the house which are infested with red-spider, the pests will spread to the Strawberries, and it is very difficult to dislodge them without keeping the plants so wet that pollination is interfered with, and rot threatened. 5. Growing the plants as close to the glass as possible. 6. In the dull months, constant and careful attention to hand pollination. 7. Liberal applications of liquid-manure two or three times a week after the fruits have begun to swell. 8. Exercise of care that the berries do not lie directly upon the soil or upon a wet surface. We are by no means confident that we have found the best methods of forcing Strawberries. We give our experience for what it is worth, and desire to correspond with persons who can help us to better results. *C. E. HUNN, and L. H. BAILEY, Cornell University Experiment Station.*

WEBBS' BARLEY COMPETITION.—The valuable prizes for Barley offered by Messrs. WEBB & SONS of Worsley, Stourbridge, brought a keen competition, and the Champion prize in Class 1, open, for £25, fell to Mr. NISBETT, Stratford St. Andrews, Saxmundham, Suffolk. In Class 2, open to Salop, Stafford, Hereford, Worcester, and Warwick, the 1st prize, £15, was awarded to Mr. E. BOMFORD, Spring Hill, Fladbury; 2nd, £10, Mr. W. CHICK, Sutton Maddock, Shifnal; 3rd, £5, Mr. G. CORBISHLEY, Bricklehampton Court, Pershore. The conditions of competition stipulated that the Barley should be one of WEBBS' varieties, and grown with Webbs' Special Barley-manure. The samples exhibited were of high quality.

BRITISH ASSOCIATION.

In the Botanical Section of the British Association a communication was contributed, "Upon a Disease of Tomatos," by W. G. P. ELLIS. From diseased Tomatos received in August, 1896, from Jersey, the associated fungi and bacteria were isolated and cultivated on nutrient gelatine, and the mycelium was traced in sections of the fruits. On removing the fruit-skin, with carefully sterilised instruments, the mycelium within the fruit formed, in a short time, the well-known sporangio-phores of *Mucor stolonifer*. Though late in the season, infection of sound plants at the University Botanic Gardens, Cambridge, from pure cultures, caused a disease resembling that of the fruits received in August and September from the grower. Experiments are in progress to determine: (1) Whether the fungi obtained, other than *Mucor stolonifer* cause disease? and (2) The site of infection; also a note "On spermatozoids in *Zamia integrifolia*," by H. J. WEBBER. Mr. Webber gave a short account of his recent discovery of the existence of large multiciliate spermatozoids in the pollen-tube of *Zamia integrifolia*, a Cycad which he investigated in Florida. The facts brought forward by the author of the paper were of exceptional interest; he described the development of an unusually large antherozoid from each of the daughter-cells, formed by the division of the generative-cell in the pollen-tube, each antherozoid being

encircled by a spirally disposed ciliate band, which the author believes to be developed from the fragments of a centrosome-like body. Mr. Webber observed the discharge of the antherozoids from the pollen-tube, and followed the passage of the motile male-gamete into the archegonium. The entire antherozoid swims into the archegonium, passing between the ruptured neck-cells. Several antherozoids commonly enter each archegonium, but only one of them takes part in fecundation. The method of antherozoid formation in *Zamia* is regarded as similar to that in *Cycas* and *Ginkgo*.

A paper "On the species of *Picea* occurring in the north-eastern United States and Canada," by Prof. D. P. PENHALLOW. Since the time of Pursh, the validity of the red Spruce as a distinct species has been generally denied by systematic botanists. In 1887, Dr. George Lawson maintained that the red and black Spruces are distinct species. This view has been sustained during the last year by Britton, in his illustrated *Flora of North America*. Prof. Penhallow's studies have led him to the conclusion that there are abundant reasons for the separation of *Picea rubra* as a distinct species. Incidentally, attention was directed to a form of the white Spruce characterised by its foetid odour, and its strongly glaucous, rigid and often cuspidate leaves, which are commonly broadened at the base. The name of *P. foetida* is suggested for this form. "Nature," October 21, 1897.

ORCHID NOTES AND GLEANINGS.

CYMBIDIUM TRACEYANUM.

A FLOWER of a very fine variety of this rare and showy species, which was illustrated in the *Gardener's Chronicle*, January 31, 1891, p. 137, is sent by Mrs. HOLLOND, Wonham, Bampton, Devonshire. The flower is over 5 inches across, the sepals and petals bright light green, profusely marked with dotted lines of a peculiar reddish-crimson tint. The lip is white spotted with red, and bearing on its crest two ridges of hair-like processes. The under-side of the column is striped with red, and the side-lobes of the lip similarly striped. Viewed in any aspect it is a charming flower, and with a strong light behind it resembles a transparent painting.

CATTLEYA DOWIANA AUREA.

Three grand flowers of this beautiful and fragrant Orchid are sent by James Fortt, Esq., Green Street, Bath, and they are remarkable, as they exhibit great variation in colour, and in the gold and crimson markings on the lip. The one has bright lemon-yellow sepals and petals, and a very large crimped labellum, the base of which is dark crimson, with golden-yellow lines radiating into a lighter yellow area inside the purplish-crimson margin, the front being ruby-crimson. Another has lighter yellow sepals and petals, and rich purplish-crimson lip, the side-lobes and basal half of the front lobe of which is closely veined with bright yellow. The third has the sepals and petals light yellow, slightly tinged with rose at the back, and the yellow-veined base of the lip is suffused with red, the front being dark rosy-crimson.

AUTUMN TINTS.

In our variable climate it is seldom we have such a fine autumn as the present, for with the exception of September 29, when '80 of an inch of rain fell, the rainfall since that date has been very light in Sussex. Neither have we had in this part any frost to speak of, and on only four occasions has the temperature fallen below freezing point, the coldest morning being that of October 8, when the temperature fell to 27.5 or 4½ degrees of frost. We have had no high equinoctial gales such as are commonly experienced, and all these immunities combined with bright sunshine have ripened the wood shoots of trees and shrubs so much, that the tints of the foliage at the present time, October 19, are charming to a degree rarely seen. To give an idea of the beautiful weather, we have only to pass along the country

lanes and take note of the hedge-rows. Some of the Blackberry leaves are of a glowing crimson, while the fruit hangs in clusters such that I have never before seen in the months of August and September, and were it not that we are reminded by the fading foliage and the shortening of days that we are nearing the end of the year, one might imagine that autumn was but commencing. Here both on the 17th and 18th the temperature reached 65° in the shade, and did not fall below 50° at night. The plantations and the plants in the shrubberies present a lovely picture at the present time, which words fail adequately to describe, or pencil to paint. The crimson leaves of the wild Cherry stand out well amongst others in the woods, as does that of *Viburnum Opulus*, the wild Snowball; while that of the Dogwood is fast changing. The beautiful golden of the Horse-Chestnut and the Elms; the bronzes of the Castanea vesca, and several others, are very conspicuous. Coming to the choicer shrubs, we must certainly give the palm to the foliage of the Ghent and Mollis Azaleas. Plants here that had grown too large, were cut down to within 2 feet of the ground three years ago, have now made large bushes again. The wood being robust, the foliage large, the latter present a far more effective display than did the flowers, although these were indeed very beautiful. Many of the Maples, too, in this respect, have this year put on very gorgeous tints. *Liquidambar styraciflua* is more beautiful this year than I have ever seen it before. Old trees that are somewhat stunted having ripened their wood thoroughly, present a picture easier imagined than described, as they have foliage of various hues. A large plant of *Ampelopsis hederacea*, which has climbed all over a dead tree, has covered its bare branches with the finest mantle of crimson that it is possible to behold. The bright foliage of the Scarlet Oak is nothing in comparison with this plant with its long loose growths hanging gracefully from the dead branches. The deeply cut foliage of *Rhus glabra laciniata*, and that of *Kelreuteria paniculata*, have been very beautiful, but the slight frost we experienced a short time back caused the former to wither. The foliage of *Rhamnus Frangula*, *Amelanchier canadensis*, *A. arbutifolia grandiflora*, *Prunus pissardi*, and some of the *Berberis*, have assumed tints this season that are seldom seen. Here, then, we have a guide as to planting, so that the most effective combination of colours may be produced in the autumn. Useful as are the evergreen shrubs for hiding ugly buildings, or making breaks against the wind, their foliage can never assume those glorious tints we have had the pleasure of beholding this autumn, neither can they have the same graceful habits that many of them possess. Take for example the long slender growths of *Deutzia crenata*, the foliage of which this season has been a perfect picture. Many of our deciduous-flowering shrubs are but too little known, for not only do their flowers in spring gladden our eyes, but the fruit of many of them is also attractive in the autumn, and the foliage, as has been pointed out, is pleasing still. There are many of our woodland walks, carriage drives, and wayside paths, that might be made beautiful at a little cost if only the right materials were employed. Such work, however, is often entrusted to those who have little taste or knowledge how to produce effect.

In the many miles of carriage-drives in some places where the soil is most suitable for growing many of the things named, and the situations all that could be desired, instead of their being planted, nothing is to be found except the common Hazel-nut, Wych Elm, or Birch, and other like coppice stuff that can be turned into faggots. Rabbits, we know, are fond of many of these, but not more so than of some others; therefore, there can be no excuse for not planting. I have never known them touch any of the Azaleas or *Deutzia scabra*, and we have thousands of these planted here; neither do they care for many of the others, unless hard driven in the winter.

The Crab, Cherry, Prunus, and many more, such as the Scarlet Oak, Maple, and Berberry, might be planted in quantity along the sides of drives. This season many of them, too, are fruiting in abundance. The Thorn is covered with its red shining

berries; the Dartmouth Crab has been most conspicuous, as also the Siberian one; while *Crataegus Pyracantha crenulata* and *Lalandi* are now covered with clusters of shining fruit. True, these last-named are evergreen, but there are some of these that may be employed with advantage along our woodland walks, or wilderness gardens, for by a judicious selection and planting, they can be introduced in such places in quantities as will render them most useful. As the time is now at hand for planting, this ought to be borne in mind, that a selection may be made. *H. C. Princep, Buxted Park.*

HOME CORRESPONDENCE.

SHRIVELLING OF VENN'S BLACK MUSCAT GRAPE.—I am very pleased to see by this week's *Gardeners' Chronicle*, p. 294, that Mr. D. T. Fish passes a few remarks on the above, and at the same time recommends what I should consider an excellent remedy for testing Vine borders. If you think the following few particulars would be any assistance to unveil the mystery connected with the Vine in question, I am most pleased to give them, namely: the depth of the border is 3 feet, and below that is a layer of drainage of 15 inches. I cannot give a definite statement of the fall of the drain from the border. I should say the fall is good, judging by the quick disappearance of the water. The width of the border inside the vinery is 9 feet, which is on a dead-level; the outside border is 12 feet wide, with a fall of 14 inches. Upon inquiry, I find the border is 15 years old, and is probably older than that. I do not suppose that excess of water is the cause of shrivelling, as the water disappears so quickly from the surface. I make a point of thrusting a stick into the border down to the drainage, to ascertain its condition before watering. If the stick comes out clean and dry, I give a plentiful supply of water during the growing season, as stated before. *Vine.*

GROWING MUSCAT OF ALEXANDRIA GRAPES.—In looking over the "Home Correspondence column" of a recent issue of the *Gardeners' Chronicle*, I noticed this heading: "Some Hints on Growing Muscat of Alexandria Vines." Now in order to be able to grow this fine Grape to perfection, gardeners are always eager for any information; but I am afraid the hints given in the letter referred to will be of little assistance, if they be not a trifle misleading. The writer says, careful ventilation is necessary during this season (September), if good flavour is to be obtained. Most growers are of opinion that careful ventilation is necessary during the whole summer and autumn, and if this is properly attended to, there will be no need for a double thickness of fish-netting to prevent scorching of the leaves. Muscats require all the sun we can give them, and the foliage, by timely ventilation, is rendered firm and able to withstand the hottest rays, provided the openings are large enough to prevent the temperature rising above the prescribed limit. Special care is necessary after dull days which tend to soften the leaves and render them more susceptible to injury; and if the clouds lift in the middle of the day, without ventilation being at once afforded, scorching is certain to follow. Better to anticipate the rise and prepare for it, than wait till a certain point has been reached. All cultivators agree in saying that the Grapes, to keep well, must be ripe by the end of September, and the flavour is better than when the ripening process is continued to a later date. Many more hints should be forthcoming to assist us in growing this Grape to perfection. *B. W.*

DO ORCHIDS DEGENERATE?—Perusal of Mr. Simcoe's remarks on this subject (*Gardeners' Chronicle*, October 16), discloses the fact that he falls into the common error of applying the term "degenerate" to subjects which die in gardens from preventable causes, and (in the present stage of our knowledge of the treatment requisite) unpreventable, and especially to the plants which cannot be induced to thrive continuously while "infested with yellow thrips," or placed in houses in which a healthy atmosphere cannot be maintained in winter. The fact that some or other of our Orchid-growers grow most of the plants he enumerates satisfactorily, proves that the decline in them complained of is not due to anything in the nature of the plants themselves, but to the want of knowledge regarding the proper treatment of them, or, in by far the greater number of instances, to the gar-

dener in whose hands they have been placed not having proper accommodation for them. Hence the remark of the hopeful modern gardener, "I cannot yet find the right place" for such and such things; and his repeated endeavours to find proper quarters for his refractory subjects. This way of looking at the matter has brought countless conquests, and more will follow if the pursuit is continued in the same spirit. But no one attempts to deny that a great number of Orchids perish under cultivation, and that, generally speaking, but little blame is to be attached, in most cases, to those who have charge of them. Yellow thrips, as Mr. Simcoe says, work great mischief among Orchids, and scarcely less harmful are the old-fashioned fumigators which most growers have abandoned in favour of the modern safe vaporizer. Necessarily the cultivation of Orchids brought from widely separated districts, and from varying altitudes, in the same house, or set of houses, presents many difficulties, but I am convinced that there is nothing in the nature of Orchids to render them more difficult to grow than the other occupants of our plant-houses. On the other hand, I am sure that a large proportion of the species will live and flower under conditions which would soon cause the death of other classes of stove or greenhouse plants. *James O'Brien.*

SEEDLING ORCHIDS.—One is struck with the great interest taken in the cultivation of Orchids, and especially in the great number of cultivators interesting themselves in the raising of seedlings. It is no strange sight to see hundreds, nay thousands, of carefully hybridised seedlings, in all stages of growth, from the smallest seedlings to the flowering stage, and the great variety of forms and colours to be found among them. What a change in a very few years! *J. Grieve.*

BORDEAUX MIXTURE AND THE POTATO DISEASE.—Lately, when on a visit to Dunbar, I was greatly struck with the effects of the spraying on hundreds of acres of Potatoes, which were as green in the haulm as at midsummer; while crops which had not been sprayed on the other side of the road were quite in a bad state. The farmers expect to lift from 1 to 3 tons more Potatoes per acre from those sprayed, and it is gratifying to see how sharp are the farmers in this part of Scotland to take advantage of this apparent blessing. *James Grieve.*

BORDER TESTER.—The border tester mentioned by Mr. Fish (p. 296), or one similar, has been in use in this country, to my knowledge, for upwards of thirty years. My first experience of it was at Wilton House, Salisbury. Mr. Challis, the present gardener, I believe, introduced it there, and as a subordinate, it was my duty to test the borders weekly. Since then I have distributed many amongst my gardening friends. The original cost is only one-sixth the price of the above-mentioned tester, thus placing it within the reach of all, as one will last a lifetime. *S., Yorks.*

—Your able correspondent, "D. T. Fish," in last week's *Gardeners' Chronicle*, p. 294, in describing this instrument, says, that up till recently there was no other means of testing Vine or other fruit-borders than by excavating small holes down to the drainage. Perhaps Mr. Fish is unaware that more than twenty years ago Mr. Sorby, then gardener to the late Mr. Russel, of Mayfield, Falkirk, had an instrument such as Mr. Kirk's then in use. Many a time I have used it on outside Peach-borders, and also in a house where large Camellias were planted out on raised borders. Whether Mr. Sorby ever brought his tester before the public I am unable to say; but as far as I know he is still residing in Falkirk; and should this meet his "eye," it would be interesting to know whether he ever did so, or if he protected it in any way. *James Cocker, Chesters.* [Several communications of the same import as the above have been received. *Ed.*]

LAPAGERIAS ALBA AND ROSEA.—In a lean-to conservatory, 21 feet in length and 15 feet wide, facing full east, we have two very fine specimens of *Lapageria* that yield upwards of 2000 blooms each year. Planted out in a prepared border of peat, loam, and silver sand, with a small addition of broken charcoal, they are given a copious supply of water once a week. The plants cover the whole roof and end of house with excellent foliage and wax-like blooms, which we find very useful for indoor decorations. They last about a fortnight, if gathered

with a good stem and placed in water, and the water is changed occasionally, at same time cutting off about half an inch of the stem. At the time of writing there is a fine cluster of the white variety with twenty-nine flowers growing on 5 inches of stem, and forming quite a bouquet in itself. I hope many more gardeners will be induced to cultivate this beautiful climber in the same position as ours. *J. R. Alyn Bank, Wimbledon.*

GOODEIA BUTTERFLY.—This beautiful hardy annual, introduced from California in 1835, is of easy culture, and the plant continues to flower all the summer. It grows about 18 inches high, and is suitable for mixed borders and small beds. Sow seeds in light soil in the first week in April out-of-doors. The seedlings must be thinned-out as soon as large enough, that each plant may become vigorous. The flowers are white, with a crimson blotch. *Wm. Smylie, The Gardens, Basing Park.*

LOBELIA CARDINALIS VAR. QUEEN VICTORIA.—For bright effective beds, or massing in borders, the above is one of the very best plants for an autumn display. It should be planted thinly in bold masses, with a groundwork of either *Viola Bullion* or *Centaurea candidissima*; either of these make a very pleasing combination, as even before the flower-spikes throw up, the dark crimson foliage of the *Lobelia* is very effective with either the *Violas* or *Centaureas*. In very sheltered, warm spots this section of *Lobelias* can be left outside all the winter, but it is much safer to lift and store them in boxes filled with leaf-mould in a cold pit, dividing and planting out again in April, after establishing them in pots by the aid of mild heat. The variety *Firefly* has larger flowers, but its foliage and habit are inferior compared with *Queen Victoria*. *W. B. G.*

DO PIGEONS EAT SLUGS?—Canon Ellacombe, in the *Gardeners' Chronicle* for October 16, wanted to know if it was true that pigeons eat slugs. There is, I think, but little doubt that these birds feed on the very small kind of slugs; but that they feed abundantly on them is another thing, and the birds are certainly a pest in any garden that they frequent, devouring the seeds and the leaves of plants, especially *Echeverias* and *Onions* in the young state. In my opinion, pigeons do a great deal more harm than good. *A. Smith, Harewood House Gardens, Hendon.*

CARNIVOROUS SLUGS.—I notice a correspondent asking for information of localities where *Testacella haliotidea* are to be found. They are very plentiful in the kitchen garden here. Early this spring some trenching operations were being carried on, when no fewer than twenty-seven were turned up in onespade-ful—two or three is a common occurrence—but I have never seen so many together before. I placed them before a meeting of members of the Beckenham Horticultural Society, and numbers of practical gardeners present, who were quite unaware of the fact that they were carnivorous; and although I offered them to anyone, as stock, they were looked upon doubtfully by some, and I brought them back again. I am of opinion that they are very beneficial to gardens, living entirely upon worms; I have often found them swallowing a worm alive—have never met with them in my experience before in the northern or midland counties or South Wales. I do not think gardeners in general are well acquainted with them; and to help some of them to distinguish this friend from a foe, I may say they are about 3 inches long, of a dirty yellow colour with brown specks; a small depressed shell is on the hinder part of the back about $\frac{1}{4}$ inch long. I have never found them out of the soil. *M. Webster, Kelcy Park Gardens, Beckenham.*

GRAPE JUDGING.—In the *Gardeners' Chronicle* for September 11, p. 186, there appeared a long letter from "Ayrshire Lad" upon the subject of judging horticultural exhibits. There are many interested in this matter, and anxious to find a better method than now obtains in the distribution of awards at flower shows. There are far too many systems employed, each individual having one of his own, thus providing scope for faddists and cranks, of which not a few receive appointment as judges. If one proper system could be adopted, there would be less wrangling among judges, and fewer disappointments among exhibitors. I agree in the main with the principle advocated by "Ayrshire Lad," and in the positions of merit assigned to varieties in the two classes, and especially with the fixed ratio between cultural and natural merits. I trust "Ayrshire Lad" has not forgotten the promise he made to

deal with mixed collections of fruit, which is even more important, so far as it affects the relative value of the different kinds. *One Interested.* [Is not the *Code of Rules for Judging*, issued by the Royal Horticultural Society, a great help? Ed.]

APERA ARUNDINACEA.—I was glad to see a figure and short note on this elegant plant on p. 282—3 of the *Gardeners' Chronicle*. Of all the smaller-growing perennial grasses, I know of none so distinct and graceful as is this New Zealand species. It is, however, by no means a new introduction to our gardens, as might be inferred from the note on p. 282. I first saw this plant at Newry at least ten, but more likely fifteen years ago, and obtained it from Mr. T. Smith, who has long had it in cultivation at Daisy Hill and elsewhere. The prettiest phase of the plant is shown when its purplish spikes or inflorescence first emerge from amongst their sheathing-leaves, when they curve gracefully downwards like the tail-feathers of a Colchican pheasant; and in many Irish gardens "*Pheasant's-tail Grass*" is now its usual name or *sobriquet*. Near walls, or rockery-stones, or natural rocks, it is quite at home, and its foliage assumes a rich fox-brown colour in late autumn and winter that renders it very attractive, apart from its inflorescences, which are very beautiful for indoor-glasses and vases if cut soon after they fully emerge, i.e., in the Pheasant's-tail phase of their beauty. The plant as well established seeds so freely, that but little difference is experienced in securing a good stock. I have some recollection of being told that this graceful *Apera* had been originally introduced by Herr Max Leichtlin; but I know Mr. Smith of Newry introduced it to Irish gardens long before it appeared in England, and it is curious to find that no mention of such an exquisite garden-plant is mentioned in the *Dictionary of Horticulture* (Nicholson), and other works even more modern. As a distinctly beautiful garden-plant in all its phases, *Apera arundinacea* cannot be too well or too widely known and utilised as a unique and desirable garden-plant. *P. W. Burbidge.*

BOOK NOTICE.

THE USEFUL FIBRE PLANTS OF THE WORLD.

MR. CHARLES RICHARDS DODGE, the "Special Agent in charge of Fibre Investigations," in connection with the United States Department of Agriculture, is to be congratulated upon the production of a most useful contribution to a subject that has occupied an immense amount of attention for several years past, namely, the utilisation and development of vegetable-fibres.

As a proof of the wide interest of the subject, we need only refer to the numerous references to fibre-plants that have been made from time to time in the *Kew Bulletin*; and to the fact that the Society of Arts in 1895 considered it of sufficient commercial importance upon which to base a course of Cantor lectures, which it will be remembered was given by Dr. Morris. Consider in the large trade that is now done in vegetable-fibres, whether for textile purposes, rope and cordage-making, or as brush materials, it is well that such a compilation as the one before us should have been produced, and it is also well that the work should have been undertaken by such a competent authority as Mr. Dodge.

As a proof of the thoroughness of the work, and as an indication that its preparation has not been hurried, the author tells us in his preface that the foundation of it was laid a little over twenty years ago, namely, at the Philadelphia International Exhibition of 1876, where raw fibres, textiles and textile manufactures were largely represented; but the information has been brought down to the present time by continued study, observation and investigation, with the result that as many as 1018 species of fibrous plants are enumerated, "the more important of which are fully described and treated from the botanical, agricultural, and industrial standpoints; being described or referred to under their scientific, commercial, common and native names (as far as the latter could be obtained and properly verified); the kind of fibre produced, the part of the plant producing it, as well as the position of the species in the vegetable kingdom."

It is in the alphabetical arrangement of the book

throughout that the utility of such a work will be found, as it appeals not only to the scientific man, but to the commercial man equally. All the names, whether scientific, commercial, or native, are printed in clarendon type, but the descriptions are all given under their scientific names, to which reference is made from the common name, as for instance, "*Assai Palm of Pava* (Braz.), *Euterpe oleracea*," and by turning up for "*Euterpe oleracea*" we find not only the full account of the Palm, but also a figure of the tree, for the book is well illustrated throughout.

Though the references to well-known fibres are very complete, and consequently of great use to those interested in fibres from the commercial aspect, it is perhaps, in the less-known plants that the book will be of extreme value to the scientific student. We take the following paragraph haphazard as an illustration of this:—"*Asimina triloba*. The Papaw of Temperate United States. Exogen. Anonaceae. A tree. Abounds in eastern middle United States from Michigan to the Gulf. Fibre. Derived from the inner bark, but now scarcely employed for any purpose. "The inner bark stripped from the branches in the early spring is still used by fishermen on the Ohio and other western rivers for stringing fish; formerly employed in making fish-nets" (C.S. Sargent). Dr. Havard states that the inner bark has a tough, fibrous texture, and in former times was commonly used by the Indians for withes, strigs, nets, &c. Savorgnan states that the bast from the inner bark of young Sprouts is very strong and lustrous.

Besides the alphabetical descriptive catalogue of fibres which, of course, occupies the main portion of the book, there is also a most useful introduction, classified under the following heads:—Definition of Fibres; the Ancient Uses of Fibres; Principal Fibre used commercially in the United States, and their Imports; Economic Investigation; Chemical Investigation; Micro-chemical Study of Fibres; the Classification of Fibres, based on Uses and Structure.

In conclusion, we can only say that we are sure that there will be a very large demand for the book, and as we understand that only a limited edition has been issued, we hope Mr. Dodge will at once proceed with the preparation of another edition; and repeat our thanks for what he has already given us.

Obituary.

E. J. BAILLIE.—Mr. E. J. Baillie, F.L.S., died at his residence, Woodbine, Upton, shortly after 10 o'clock on the 18th inst. Mr. Baillie was only forty-six years of age, and he leaves a widow and a family of ten to mourn their loss. Rather more than thirty years ago he entered the firm of Messrs. F. and A. Dickson & Sons, seed merchants and nurserymen, Eastgate Street, Chester, and his business career was most successful. He commenced as a junior in the correspondence department, the charge of the department eventually falling to his care and supervision. He was next appointed cashier and confidential adviser of the firm, and afterwards became a partner, and subsequently managing partner of the business. When the two firms of Dicksons were amalgamated, Mr. Baillie became deputy chairman and a managing director of Dicksons Limited. Since the death of Mr. Alfred Dickson he had been more intimately connected with the extensive nursery department.

His labours on behalf of the Grosvenor Museum will never be forgotten. For some years he had acted as honorary secretary and treasurer to the managing body of that institution. He was a fellow of the Linnean Society, and the members of the Chester Society of Natural Science were indebted to him on several occasions for enjoyable rambles when he conducted them, through the Nurseries and elsewhere in the neighbourhood. For his services to the cause of natural science he was awarded the Kingsley Memorial Medal. He was one of the prime movers in the formation of the Chester Paxton Society, and, a true lover of art, he practically initiated the Chester Guild of Arts and Crafts. Mr. Baillie was ever striving to popularise

art, and the citizens have him very largely to thank for the display of pictures from time to time at the Museum, and also for the art exhibition opened some months ago by the Duke of Westminster.

A personal friend and enthusiastic disciple of John Ruskin, he had been for some years, and indeed was at the time of his death president of the Ruskin Society, Liverpool. It was through his instrumentality that the exhibits at the recent conversations in the Museum were enhanced by several fine specimens of Ruskin's artistic work. Deceased was a clever artist, having a remarkable facility for transferring faces and striking bits of scenery to paper; while another accomplishment in which he shone was that of shorthand.

A Fellow of the Royal Horticultural Society, deceased on several occasions lectured before this body; while articles on fruit culture frequently appeared from his prolific pen in various publications. As is well known, Mr. Baillie was an enthusiastic vegetarian, being one of the Vice-Presidents of the Vegetarian Society. He took an active part in the Vegetarian Conference in Chester two years ago, and it is a melancholy coincidence that the Society celebrated its Jubilee in Manchester on the very day of his death.

Mr. Baillie had strong spiritualistic leanings, and he was one of the few members in this district of the Psychical Research Society. Deceased never interested himself in political matters. In religion he was a Presbyterian.

MR. RAND.—We regret to hear of the decease of Mr. Rand of Para, a gentleman much attached to the study of Orchids, and who has been the means of introducing many species to this country.

SOCIETIES.

ROYAL HORTICULTURAL.

OCTOBER 26.—An ordinary fortnightly meeting of the Society's committees took place on Tuesday last in the Drill Hall, James Street, Westminster. It was certainly a rather day among the meetings of the year, and the attendance was greater than on any other occasion this season. V. M. H. (Victoria Medals of Honour) attracted many persons, including those to be honoured, and many who were not. Of the sixty selected gentlemen, more than two thirds were present to receive the symbol of distinction from the hand of Sir Trevor Lawrence, Bart., the President of the Society, who distributed the medals in the presence of a very large company—a larger company, indeed, than accommodation had been provided for. There was much enthusiasm about the proceedings, and all of the medallists appeared to appreciate the honour conferred upon them. There was much speaking at the luncheon in the "Hotel Windsor" (elsewhere reported); but at the more public proceedings in the Drill Hall, there was no speech made by or on the behalf of the recipients. As there were so many present this would have been inconvenient—but, at the same time, something of the kind seemed called for. The display in the hall was one fitting the occasion, and exceedingly bright it was. Chrysanthemums in groups, and as cut flowers, were the most prominent feature. Mr. Elwes' Nerines were pretty, and obtained several awards. There were many pretty Orchids, and numerous miscellaneous plants. Fruits were plentiful, and included large collections of Apples and Pears. A new Melon and a new Grape obtained awards. Vegetables in several exhibits were good, and two awards were made to Turnips.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. Owen Thomas, John Laing, Chas. T. Drury, H. B. May, R. Dean, E. Molyneux, Geo. Stevens, Geo. Egleheart, Jas. Huxson, J. Fraser, J. D. Pawle, Chas. Jeffries, H. J. Cutbush, Jas. Walker, C. E. Pearson, Chas. E. Shea, Geo. Gordon, Chas. Black, H. Turner, Geo. Paul, J. T. Bennett-Poë, H. Selfe Leonard, Geo. Nicholson, and D. B. Crane.

H. J. Elwes, Esq., Colebourne, Andoverford, Gloucestershire, exhibited a group of seedling Nerines in flower. The varieties in colour and shade were most attractive. The following were selected for Awards of Merit: Lady Mary Shelley, light pink; Lady Dorington, light pink, with deep rose line running through the centre of the petals; Lady Lucy Hicks Beach, deep crimson; Lady Bromley, a curious association of red and purple, the purple line running through the centre of petals; Lady Llewellyn, dark carmine; Lady Flouke, pale rose; Countess Bathurst, white, with a line of deep rose; and Lady Lawrence, reddish-salmon. Several species and hybrids were also shown by Mr. Elwes, and a Silver Flora Medal was awarded the group.

Messrs. Jno. Laing & Sons, Forest Hill, London, S.E., showed an excellent group of plants of a miscellaneous character, inclusive of species with decorative foliage, and a few flowering plants (Silver Flora Medal).

Messrs. Wm. Paul & Son, Waltham Cross Nurseries, Herts, made yet another exhibit of cut Roses, really wonderful in variety and attractiveness for the last week in October. The collection was distinguished by the Award of a Silver-gilt Banksian Medal.

A group of half-a-dozen plants of *Gesnera amabilis* in flower, from Mr. F. Blair, gr. to the Duke of Sutherland, Trentham, Staffordshire, attracted some attention, and the plants uncommonly well portrayed its exceptionally free-flowering habit. The flowers are white, shaded outside with cream.

Mr. T. S. Wane, Hale Farm Nurseries, Tottenham, had Carnations submitted for Certificates; and Miss Emmett, 6, St. Charles Square, North Kensington, exhibited some models of flowers in a glass case. The exceedingly clever manner in which Nature was imitated, and incidentally the taste in which they were grouped, were conspicuous to everyone present. The species mimicked were *Vitis quinquefolia*, *Habenaria fusca*, *Carpinus americana*, *Solidago canadensis*, and *Disa grandiflora* (Silver Medal).

A most attractive group of *Adiantum*, *Ferns*, and *Begonias*, was staged by Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton. The *Adiantums* included some beautiful plants of *A. Farleyense*, and the *Begonias* were *Gloire de Lorraine* (Silver Flora Medal).

Messrs. W. Cutbush & Son, Highgate Nurseries, London, N., had a very pretty group of plants arranged upon the floor near the door. The background contained some large-flowered *Chrysanthemums*, fine *Palms*, and *Dracenas*; and the forefront some beautifully-flowered plants of *Begonia Gloire de Lorraine*, winter-flowering *Carnations*, *Ericas*, and a few berried plants (Silver Banksian Medal).

Flowers of Sunflower *Lockinge Favourite* were shown by Mr. W. Fyfe, gr. to Lord Wantage, Lockinge Park, Wantage. It is an exceptionally free-flowering variety, in habit between the miniature and giant strains.

Messrs. J. A. Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea, obtained a First-class Certificate for a new species of *Marattia* M. Burkel. The tripinnatifid fronds are glossy polished green; and the pinnate rachis light green in colour, and of much substance, causing each frond to droop. The frond as seen was about twenty-one inches long, with eight almost opposite frondlets, seven inches long, each bearing about nine pairs of pinnae with lanceolate slightly toothed segments.

CHRYSANTHEMUMS.

The leading group came from Mr. W. Wells, Earlswood, Redhill, who, departing from the usual custom of arranging the plants in a semicircular form, had his at varying levels, and introduced some boards of blooms in the foreground. Among the leading varieties were G. J. Warren a pale yellow sport from Madame Carnot, which it resembles in all respects but colour, and it is likely to be as valuable as an exhibition variety (Award of Merit). *Oriental Topaz*, a pale sulphur-yellow incurved, of large size, in the way of Lord Alcester; *Directeur Liebert*, a refined Madame E. Audiguer; N. C. S. Jubilee, a fine incurved Japanese, in colour delicate pink, with a silver reverse; *Australie*, Mr. H. Gardener, a rose-tinted Japanese *Anemone* of good properties, but scarcely sufficiently distinct; Dorothy Seward, Madame G. Bruant, M. E. André, William Seward, &c. (Silver-gilt Banksian Medal).

A bold and striking group came from Messrs. J. Veitch & Sons, Ltd., which included capital illustrations of William Fyfe, Madame Gustave Henry, Simplicity, Pride of Madford (very fine), Mrs. C. Black, Mrs. S. C. Probyn (very fine), M. Chénod de Leché, Mrs. G. W. Palmer, Dorothy Seward, Modeste, the new yellow Louis Bochner, &c.

Mr. T. S. Wane, Hale Farm Nurseries, Tottenham, also staged a grand group, alternated with other plants. He had Madame Gustave Henry, Western King, Simplicity, Madame Xavier Ray Joveris, Rena Dula (incurved), Glory of the Pacific, Madame E. Roger, Modestum, Duke of Wellington, &c. (Silver Banksian Medal).

In the way of collections of cut flowers, Mr. W. J. Godfrey, nurseryman, Exmouth, took the lead, filling one side of a table with a large number of finely-developed flowers, novelties greatly preponderating. Awards of Merit were made to Lady Ridgway, the large, incurving, broad-petalled flowers having a soft lilac-purple colouring on the surface, with an amber reverse: this is likely to prove one of the very finest varieties of the season; Madame Philippe Revlere, a large, full, broad-petalled white Japanese, of fine character; Ella Curtis, a large, full, and striking flower, of the type of *Boule d'Or*, but a little paler in colour; Simplicity, a pure white Japanese, of good shape, and long, drooping basal florets; Lady Byron, pure white, a large-spread, drooping flower, of fine substance; Modestum, a handsome large yellow flower, of fine form; and Sunstone, pale yellow, very pleasing in tint, and high'y promising (Silver-gilt Floral Medal).

Messrs. H. Cannell & Sons, Swanley, in a collection of cut *Chrysanthemums*, had Lady Hanhan, a sport from Charles Davis, and like it, will be certain to prove a valuable exhibition flower, though inclining to vary; its true, or rather best character should be ruby-pink, with a large, bright golden centre (Award of Merit). Robert Powell, a large, full, incurved Japanese, in the way of E. Molyneux, pale chestnut, with amber reverse (Award of Merit); N. C. S. Jubilee, an incurved Japanese of a soft pinkish-lilac tint, very pleasing (Award of Merit). Also several bunches of bright and pleasing single varieties were shown, the most promising being King of Slam, crimson; Rosebank, pale rose-pink; Willie Chapman, blue-pink; and Blanche Chapman, soft pink (Silver Banksian Medal).

Mr. N. Molyneux, The Gardens, Rookesbury Park, Ware-

ham, Hants, had blooms of Mrs. N. Molyneux, a large, solid, white incurved variety, like Queen of England, as shown, but probably likely to prove its superior.

Mr. R. Owen, nurseryman, Maidenhead, had Lady Phillips, like a pale Madame E. Audiguer; Soleil d'Octobre, pale yellow, a flower of good shape; Comtesse de Boulaucourt, deep yellow; Mrs. Sarah Owen, an incurved, in the way of R. Bahuant, bronze, tipped with orange, &c.

Mr. George Wythes, gr. to Earl Percy, Slon House, Isleworth, set up several bunches of finely-developed blooms, rising out of a bed of dwarf Ferns, with Palms at the back; this was a charming contribution to the meeting (Silver Banksian Medal).

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. Jas. O'Brien (Hon. Sec.), H. Ballantine, W. H. White, F. C. Jacomb, F. J. Thorne, T. W. Bond, W. H. Young, E. Ashworth, H. J. Chapman, H. Williams, J. Douglas, S. Courtauld, De B. Crawshaw, H. M. Pollett, and A. H. Smees.

At this meeting one of the finest shows of Orchids of the season was made, many of the exhibitors staging very important groups.

Messrs. J. A. Veitch & Sons, Ltd., Royal Exotic Nursery, King's Road, Chelsea, had a splendid group extending a considerable distance down one side of the central staging, which secured the Award of a Silver-gilt Flora Medal. Among the many fine hybrids shown in this group were *Cattleya* × *Olivia* (intermediate, Trianel?), a charming delicately tinted flower of an uniform peach-blossom hue (Award of Merit); and *Cattleya* × *Melpomene* (Mendel?), another pretty light coloured hybrid, with sepals and petals light-rose; lip white tinged with pink, and with a light yellow centre (Award of Merit). Another singular novelty was *Phalo-Calanthe* × *Insuperata* (P. grandifolius?), C. Masuca?) with a spike of flowers with ovate-acuminate sepals and petals, and broad, flat labellum, the whole coloured rosy-mauve in several shades. The plant was distinctly intermediate between the two parents, but the flowers approached in form and colour much more closely to *Calanthe Masuca*. Prominent in the group were the showy and useful hybrids, viz., *Laelio-Cattleya* × *Lady Rothschild*, L.-C. × *Statteriana*, and L.-C. × *Decia*; L.-C. × *Pallas* and its variety *superba*, L.-C. *Tiresias*, L.-C. × *Ino*, L.-C. × *Pleandria*, and L.-C. × *Baroness Schroder* (L. Jongheana?), C. Trianel?), the warm rose-tinted flowers of which constitute it one of the prettiest of its class. Of the hybrid *Cattleyas* C. × *Wendlandiana* and C. × *Mantini* were very fine, and richly coloured; and in the group was a large number of hybrid *Cypripediums*, C. × *Loosanum* varieties, C. × *Arhurianum*, C. × *cananthum* superbum, and others being represented by large specimens, bearing many flowers. Also remarkable in the group were the new *Dendrobium taurinum* amboinense; *D. stratiotes*, *D. Desarel*, *Epidendrum Wallisi* and its singular hybrid E. × *Wallisi-ciliare*; fine plants of *Cattleya maxima* a number of varieties of *C. labiata* which were very effective grouped together in the centre; the elegant *Cyper-orchis elegans*; the pretty white *Calogyne Veitchii*, *Vanda Sanderiana*, fine examples of *Cattleya Dowiana aurea*, and many other showy species.

R. I. Measures, Esq., Cambridge Lodge, Cambeswell (gr. Mr. H. J. Chapman) staged a very pretty group which secured a Silver Flora Medal. It consisted of twenty-five fine and distinct varieties of *Cattleya labiata*, the most remarkable of which were the handsome, white C. l. "R. I. Measures," and the uniform light rose hue C. l. *Ilacina*. The most remarkable new plant in the group was *Laelia purpurata* Mrs. R. I. Measures, a very handsome and distinct form with bluish-white sepals and petals, the latter being distinctly veined with close lines of rose-purple colour over the greater part of their surface. The lip was white at the base, striped with fine purple lines, the front dark purple (Award of Merit). Also in the group was a fine specimen of *Oncidium ornithorhynchum* album, with seventeen spikes; some good *Cattleya Dowiana*, *Dendrobium aureum*, *Cattleya Bowringiana* *Ilacina*, hybrid *Cypripedium*, &c.

WALTER C. WALKER, Esq., Percy Lodge, Winchmore Hill (gr., Mr. Geo. Cragg), was awarded a Silver Banksian Medal for a pretty group of *Cattleya labiata*, together with good examples of *Oncidium Forbesii*, *O. pretextum*, *Cattleya Bowringiana*, a fine form of *Odontoglossum crispum*, with seventeen flowers on the spike; *O. Madresae*, &c.

A Silver Banksian Medal was awarded to Mrs. WINOFIELD, Amphill House, Bedfordshire (gr., Mr. W. J. Empson), for a good group of well-grown specimens of *Cattleya labiata*, with which were arranged *Oncidium varicosum* and other showy Orchids.

Sir Trevor Lawrence, Bart., Burford, Dorking (gr., Mr. W. H. White), showed a fine plant of *Laelia Perrini* alba, Burford variety; a white form having a pale pink front to the lip as in L. P. nivea (Cultural Commendation). FRANK HARDY, Esq., Tyntesfield, Abington-on-Mersey (gr., Mr. T. Stafford), showed *Laelia pumila* albens, a very fine white variety, with distinct purple-crimson markings on the front of the lip (Award of Merit); and *Cattleya Hardyana* magnifica, one of the finest and richest in colour of any of the varieties of this variable natural hybrid (Award of Merit). Mr. HARDY also showed three fine *Cattleya aurea*, a *Laelio-Cattleya* × *Tydesa*, and a pretty, dark-veined *Cypripedium Charlesworthii*.

R. BROOMAN WHITE, Esq., Arddarroch, Gaelochhead, Dumfrieshire, showed *Odontoglossum crispum* "Sunlight," a very fine variety with large white flowers, slightly tinged with rose, and bearing some large blotches of red-

dish-brown, the petals also having numerous small purple spots (Award of Merit).

C. K. WILD, Esq., Bramcote, Weybridge (gr., Mr. R. Pallant), showed *Cattleya Bowringiana* "Wild's variety," bearing a very fine inflorescence of the largest and brightest coloured flowers of any of the species yet shown (Award of Merit and a Cultural Commendation).

ELIJAH ASHWORTH, Esq., Harefield Hall, Wilmslow, Cheshire (gr., Mr. Holbrook), showed two plants of *Cypripedium* × *Haynald-Chamberlainii* (*Chamberlainianum* × *Haynaldianum*), the first cross of *C. Chamberlainianum* that has appeared. The upper sepals were white, green at the base, and bearing some fine purple lines; petals green marked with purple, lip rose-purple margined with greenish-yellow (Award of Merit); and *C. × Arthurianum*, var. *E. Ashworth*, a fine flower with distinct dark purplish-brown markings.

Messrs. W. L. LEWIS & Co., Southgate, showed a small group of a good type of *Laelia pumila*, the best of which was *L. pumila* magnifica, a very large and showy flower (Award of Merit); also *Laelia longipes* (Botanical Certificate), a plant known in gardens as *L. Lucasiana*.

Messrs. HUGH LOW & Co., Clapton, showed a group of fine *Vanda corulea*, with which were arranged *Cypripedium* × *Fascinator*, *C. Lecanum superbum*, *C. L. virescens*, *C. Arthurianum*, and other showy Orchids.

Messrs. F. SANDER & Co., St. Albans, staged a group in which were good varieties of *Cattleya labiata*, *C. aurea*, *Cypripedium insignis* Sanders, *C. insignis montanum* varieties, *Miltonia spectabilis* Morelliana, *M. vexillaria*, *Laelia monophylla*, *L. pumila*, *Sophronitis grandiflora*, *Vanda corulea*, *Oncidium ornithorrhynchum*, *O. tigrinum* with variegated foliage; *O. Krameri*, and *Habenaria carnea*.

Messrs. B. S. WILLIAMS & SONS, Holloway, showed a group consisting of *Vanda tricolor insignis*, *Zygopetalum Klabechorum*, varieties of *Cattleya labiata* and *C. Bowringiana*, *Laelia Perrini*, *Cypripedium* × *Barteti*, *C. × Arthurianum*, *C. × giganteum*, *C. × Pitecherianum*, Williams' var., *C. insignis Wallacei*, *Dendrobium bigibbum*, *Oncidium crispum*, and *O. Phalanopsis*.

Mrs. BRIGGS-BURY, Bank House, Accrington, showed *Cattleya* × *Adonis*, said to be the result of a cross between *C. Mossiae*, and *C. Warscewiczii*. The flower resembled a fine light-coloured form of *C. Warscewiczii*, but the yellow colour usually seen in that species was almost entirely absent, it being replaced by cream white; the front lobe of the lip was marbled with clear rose-colour. Mrs. Briggs-Bury also showed *Cattleya Warscewiczii splendens*, with a very fine crimped labellum; *Cypripedium Arthurianum pulchellum*, Bank House variety; and the yellow *C. insignis* Ballie.

J. BRADSHAW, Esq., The Grange, Southgate, N., showed some remarkable varieties of *Cattleya labiata*, among which were *C. l. Ruby*, a very finely coloured dark form; *C. l. glauca*, having a peculiar slate-blue tint; and *C. l. Etona*, pure white, with bright purple front to the lip; also *Cypripedium purpuratum*.

Captain THOS. A. JULIAN, Woodside, Plymouth, showed two fine varieties of *Dendrobium Phalanopsis*, the one a white variety with a pink-hued lip, similar to *D. P. Rothschildiana* (*Gard. Chron.*, Dec. 3, 1891, p. 668); and the other the light rose-tinted *D. P. delicatum*.

THOS. STATTIE, Esq., Staud + all, Whitefield, Manchester (gr., Mr. R. Johnson), again showed the distinct *Cattleya aurea* var. *Johnsoni*, for which he obtained a First-class Certificate on Aug. 11, 1885—a good evidence of cultural skill, and a proof that Orchids need not necessarily degenerate if properly tended.

C. L. N. INGRAM, Esq., Elstead House, Godalming (gr., Mr. T. W. Bond), showed *Laelia-Cattleya* × *Diarmid* (*L. Perrini* × *L. C. elegans* Turner); *L. C. × Lady Rothschild* (*L. Perrini* × *C. Warscewiczii*); *L. C. × Homère* (*L. Perrini* × *C. Percivaliana*); and *Cattleya Bowringiana*, Ingram's var.

ROINALD YOUNG, Esq., Fringilla, Linnet Lane, Sefton Park, Liverpool (gr., Mr. Poyntz), sent *Cattleya Dowiana* aurea, Young's var., distinguished by the distinct yellow area on the labellum; and *Cypripedium* × *Clio*.

E. HOCKLIFE, Esq., The Hall, Uppingham, Rutland (gr., Mr. Cant), showed *Cattleya* × *Hardyana* Hocklife's var., a distinct variety, the segments of which were tinged with lilac, and the yellow lines on the lip were very narrow, and displayed on a peculiar reddish-purple ground.

FRANK LLOYD, Esq., Combe House, Croydon, showed *Cattleya labiata* with abnormal flowers.

T. W. SWINBURNE, Esq., Comdean Hall, Winchcombe, showed *Odontoglossum grande*, in which two flowers had joined.

Frau IDA BRANDT, Riesbach, Zurich (gr., Mr. Schlecht), sent *Miltonia spectabilis* rosea, *M. S. Morelliana* illustris, and *Cattleya Bowringiana*; and G. W. LAW-SCHOFIELD, Esq., New-Hall-Hey, Rawtenstall (gr., Mr. Shill), sent *Laelia purpurata* Annie Louise, with rose-veined petals, resembling *L. p. Mrs. R. L. Measures*, but the markings were not so clearly defined.

Fruit Committee.

Present: Philip Crowley, Esq., chairman; and Messrs. T. F. Rivers, Geo. Bunyard, Jos. Cheal, W. Crump, A. H. Pearson, A. F. Barron, W. J. Empson, Alex. Dean, Jas. H. Veitch, W. Farr, Geo. Wythes, H. Balderson, F. Q. Lane, Jas. Smith, J. Willard, Robt. Fife, and J. Wright.

A number of dishes of both Pears and Apples were staged in the Veitchian competition for flavour, and the result was that 1st prize for Apples went to Cox's Orange Pippin, from Mr. HERRIN, gr. at Droghda. The fruit was from a bush tree on the Paradise Stock. 2nd, American Mother, from Mr. Geo. Woodward, gr. to ROGER LEIGH, Esq., Barham Court, Maidstone. The best Pear was that excellent variety,

Doyenné du Comice, from Col. BRYMER, M.P., Ilington House, Dorchester. The fruits were obtained from a tree on east wall, stock the Quince, and in a light loamy soil. 2nd, Emile d'Heyst, from Mr. WOODWARD.

A new white Grape was shown by Mr. T. Bradshaw, gr. to the Marquis of LANSDOWNE, Hillsborough Castle, co. Down, Ireland. It is said to be the result of a cross between Muscat of Alexandria, and White Gros Colman, the latter being the seed parent. Three bunches were shown, the largest of which had been grown in a late house and was very unripe. The two from an early house also differed in flavour from each other. The best was of tolerably good flavour, pleasant to the palate, and pretty in appearance. In habit of bunch, the character of Gros Colman is distinctly evident. If the variety proves to be a good late keeping Grape, it will be valuable.

A seedling Melon, out of Beauty of Syon × Syon House, from Mr. GEO. WYTHES, Syon House, Brentford, obtained an Award of Merit. It is named Excelsior, has a straw-coloured netted exterior, salmon-coloured flesh, and good flavour, especially for the season.

Mr. A. OUTRAM, 7, Doria Road, Fulham, exhibited a dish of capital fruits of Royal Dutch Medlar; and Mr. J. Crook, gr. to W. H. EVANS, Esq., Forde Abbey, Chard, showed a dish of Cox's Late Red Plum, and a dish of Tomatos from the open.

Awards of Merit were recommended to Turnips Model White, and Golden Ball both from Messrs. DOBBIE & Co., Rothsay and Orplington, Kent. Both of these types are excellent in every respect. Messrs. DOBBIE also showed plants of their selected Parsley, and their Victoria Parsley, Parsnips, &c.

Messrs. JNO. LAING & SONS, Forest Hill Nurseries, London, S.E., staged a collection of Apples and Pears. The exhibit included about 10) dishes, and was awarded a Silver Gilt Knightian Medal.

Another collection from Messrs. J. CREAL & SONS, Lowfield Nurseries, Crawley, included about eighty dishes of fruit, most of them Apples, and about twenty-five dishes of Pears; a Silver-gilt Knightian Medal was awarded in this case also.

A Silver-gilt Knightian Medal was deservedly awarded for a collection of Grapes exhibiting very successful culture, shown by C. BAYER, Esq., Forest Hill (gr., Mr. Tayler). There were two or three bunches of the following varieties: Trobiano, Gros Colmar, Gros Maroc (exquisite), Foster's Seedling, Black Hamburg, Altwick Seedling, Mrs. Pince, and Muscat of Alexandria.

Messrs. B. CANNELL & SONS, Swanley, Kent, made a display with some excellent vegetables from their Eynford Nurseries. Capital Onions of Ailsa Craig, Improved Wroton, and Reading Improved; Cannell's Mammoth Leeks, thick, and well blanched; Cannell's First Prize and First Class Carrots of the Intermediate type; Best-of-All Beet, very fine Autumn Giant Cauliflower; and some heads of Cannell's Defence Cabbage, an exceedingly pretty well-shaped Cabbage, good hearted, in which there is little waste. About forty dishes of Potatoes, representing the choicest varieties, were also shown (Silver-gilt Knightian Medal).

Messrs. CARTER & Co., High Holborn, London, were awarded a Bronze Knightian Medal for a collection of twenty-two varieties of Beetroot.

Royal Horticultural Society's Victoria Medal of Honour.

At the invitation of the President and Council of the Royal Horticultural Society, a large proportion of the sixty gentlemen selected to receive the Victoria Medal of Honour was present at a luncheon on Tuesday, October 26, at the Horticultural Club Rooms, Hotel Windsor, Victoria Street, Westminster, prior to the distribution of the Victoria Medals in the Drill Hall. Sir TREVOR LAWRENCE, Bt., the President of the Society, occupied the chair, and he was supported by several members of the Council.

After luncheon the President gave the toast of "The Queen, and Patron of the Society," which was heartily responded to.

The President then proceeded to explain the object of that gathering. He said there was a strong desire early in the present year on the part of the Royal Horticultural Society to do something to celebrate the long reign of Her Majesty. The Queen had for many years been patron of the Society, and many members of the Royal Family were Fellows, while they would also recollect that the late Prince Consort was for some years their President. For the greater part of a century the Society had presided over and in a great measure directed the gardening interests of this country, and he thought they would agree with him, that the Queen being Patron of the Society, it was only becoming that the Society should celebrate the remarkable occasion of Her Majesty's Sixty Years' Reign. If we were to enter into the subject of the great advances made in horticulture, and in all branches of gardening, during that period, it would take up too much of their time, and, besides, those subjects had been dealt with recently by persons far abler than he was to deal with them. He would only say that those people must be blind indeed who could not see the enormous strides which gardening had made in this country during the last fifty or sixty years. He ventured to think that the great strides that had been made illustrated the fact—as a fact it undoubt-

edly was—that gardening was by no means one of the pleasures of the rich only. He remembered when he had the pleasure of representing in Parliament rather a poor part of London, Battersea and Wandsworth—being struck by the great and trouble which the people took with their window-boxes, and he was sure that as great an interest was taken in gardening by the poorer people as by the rich and wealthy. It would be an exaggeration to say that gardening was the mother of all the virtues; but at the same time, he thought they might say, with perfect truth, that there were very few pursuits and occupations with so small an admixture of the selfish as gardening.

When the question arose as to what the Royal Horticultural Society was to do to celebrate the Diamond Jubilee, need scarcely say that the fertile brain of their Secretary had a suggestion to make. He did not mean to say that the Secretary's brain was the only brain that was fertile, but the fertility of his brain produced a more sturdy plant than the fertility of other brains. He might say that it was the inspiration of the Secretary that they took into consideration the proposal of the establishment of the Victorian Medal of Horticulture.

Many projects were considered, and looked at all round, but it became perfectly clear that the Secretary's suggestion was by far the best of all that came before them, and himself as President of the Society, was instructed to Her Majesty's gracious permission to establish the Medal. They were all aware that Her Majesty scrupulously abstained from taking any prominent share in choosing the method of celebrating her Jubilee, but the Queen graciously intimating to the society her assent to their proposal, and expressing opinion that there could be no possible objection to it, being so they decided on carrying out the suggestion of the Secretary, and he, personally, was very glad they did.

He was glad to see one of their lady members present that day, and they would all feel that nothing could be more becoming when they were celebrating the Jubilee of Gracious Majesty, than that some members of her own sex were medallists. He did not think anything could be more conclusively than that gathering, that the society did wisely in adopting the suggestion of their Secretary. He saw around him men of the greatest eminence, and thanked them for their presence that day. When the question arose as to who were to be the recipients of the Medal, it was thought right that every department connected with the art and science of gardening should be represented. It was possible care was taken in the selection, and if names appeared on the list and others did not, it was understood that there were good reasons both for the selection and the exclusion. In the first place it would have been at all becoming if the Council, who had the selection of the names, should have distributed the Medal among their own members. Then there were reasons—reasons—private reasons—why certain gentlemen, who invited to become recipients, thought it their duty to do so. The result was, that the recipients of the Medal included eight botanists—he took them first, as science being things was the moving-power of the world at the present time. At the head of them they had the distinguished botanist who sat on his right (Sir Joseph Hooker) man who during a long life had done more valuable work for the science of botany than any one other man he had achieved. Then they had many collectors, and hybridists they had, representing the gardening trade, for nurserymen and men engaged in business. They had members who represented the market aspect of gardening and they had twenty-seven medallists representing professional gardeners, fifteen of whom were amateurs, and twelve professionals. Some people, perhaps, would think that proportion in that case should be reversed! Then they had one landscape gardener, and two members of the cultural press.

He could assure them that the greatest possible care was taken in the selection in every case. No the Council had made mistakes in including names some might think ought to have been omitted, and in omitting names that others would think ought to have been included; but they had done their best to secure a representative list of names.

He would here like to say that the Queen, having sanctioned the establishment of the Medal, it would be distasteful if it were used for purposes of advertising.

In conclusion, the President expressed his gratitude to those who had attended that gathering, and explained the design for the Medal was the work of a lady—Margaret Gies—who had carried out a very graceful commission in a most satisfactory way.

Sir JOSEPH HOOKER, in responding for botanists, the President and the Council for the very high honour had conferred upon him in placing his name among recipients of the Victorian Medal, among whom he could be found some whose claims to respond to the toast beyond his own. There were those present who represented three generations of horticulturists, and

had introduced more new plants than ever Kew ardens had—men in the front rank, the results of whose labours were to be seen throughout the land alike in the gardens of prince and of the peasant. However, he gladly accepted the proud position of responding. The duties performed at Kew were very various—the introduction of new and rare plants, their classification, identification, description, and illustration, and what was of more importance, the propagation of useful plants for the benefit of mankind. But what good would all this be without practical horticulture? The gardens of Kew would be practically wasted, and it behoved botanists to consider how greatly they were indebted to horticulturists for some of the most precious possessions of the botanical world. Therefore he would impress it upon them that botany and horticulture—practical horticulture—must go hand in hand. So long as that was the case, both botany and horticulture would prosper.

Dean HOLK also responded. At the outset he remarked that if they were doing honour to Her Majesty, the one lady member who was present (Miss Jekyll) was certainly the "Queen of Spades!" He went on to say that in associating his name on that occasion, and in such company, they had greatly added to the enjoyment of a day which he should always regard as one of the brightest of a long and happy life, so long, indeed, that he thought he could claim the title he coveted in the great University of Cambridge, next to that of Senior Wrangler, and style himself Senior Medalist; and a life so happy because it had been spent largely in scenes which he loved most, and with men like themselves, whose tastes and habits were in such complete accord with his own. If there was such a thing as righteous pride, and if it was justifiable to put a little "side" on, he thought they had a right to wear it that day, and he was not sure that they should not be permitted to assume the demeanour of that gentleman whom Theodore Hook saw swaggering along one day and who was asked, "Sir, are you anybody in particular?" For himself, he had been for some days in training and preparation for this supreme event. On Thursday it was his privilege to entertain Her Royal Highness Princess Christian at the Deanery, and on Saturday it was his privilege to attend the Prince of Wales as Grand Chaplain, and now to-day he had the distinguished privilege of paying honour to two queens—the Queen of Flowers—the Rose—whom gardeners loved, and the Queen of England, whom all England revered. But it was not pride which was uppermost in his thoughts that day. On the contrary, it was a very humble thankfulness that they had been permitted to add to the purest of human pleasures, and that they had been allowed to see the fruition of their success! It was impossible for an old man in a retrospect of the years that had gone, not to have sweet solace in the thought that he had been permitted in some degree to help in brightening the lives of others by means of a healthful and harmless occupation among things pleasant to the eye, and good for food. The Society of which Sir Trevor Lawrence was President, with its Council and its unwearied secretary, had done excellent work for a long time past in many places, by promoting the science of horticulture; and although, of course, he was prejudiced on the present occasion, he ventured to say that the institution of the Victorian Medal would prove a grand encouragement in quickening the ambition and energies of those men who would excel hereafter in botanical science and in horticultural skill.

Mr. SHERRWOOD, who was next called upon, said after the excellent speeches to which they had listened with such pleasure, they would forgive him for being brief. He would not dwell upon the marked improvement in the seed and nursery trade that had taken place during the last sixty years, as during the last few weeks Mr. BUNYARD and Mr. BURTON had written exhaustive papers on those subjects. He would only say that the Royal Horticultural Society would be heartily thanked for all it had done—a work which would be recognised by all the gentlemen who had been brought together that day. None of them would easily forget the bestowal of the Jubilee Medals. He was glad the President referred to the Council in this connection, because there were many who thought that the members of the Council should certainly have received some recognition. He could only hope that some such recognition would follow.

Mr. HUDSON (gardener to Baron Rothschild) was the last gentleman to respond, and he did so on behalf of gardeners in general. He said they ought to congratulate themselves that they steered clear of the controversies which they saw going on in other professions. He had been identified with the Royal Horticultural Society for close upon thirty years, and he had always endeavoured to carry out three principles—to serve his employer to the best of his ability, to further the work they had at heart, and to assist those of the craft who needed assistance.

BARON SCHRODER then rose, and said that he had been asked to propose the "Health of the President and the Council of the Royal Horticultural Society," and he

considered it a great honour, among so many distinguished gentlemen, to have been selected for that duty. He felt that he could hardly do justice to the toast, as he was no speaker, but he thought that, as an old and retired member of the Council, he had had a great deal of experience of the troubles and anxieties connected with the office of President of that great Society. He therefore felt that all honour was due to those gentlemen for the way in which they had brought the Society to its present splendid position. He well remembered when he was called to the Council. At that time they were located at South Kensington where they had a large and lofty conservatory, but a wretched Council Chamber. He also remembered that at that time the Council was very much divided. Some were for continuing in the old groove, and seeing the old Society gradually die out; but there were others, and at their head was Sir Trevor Lawrence, who believed they would be doing right in breaking away from the old traditions. That was a grave step to take. They had many consultations together. They had no money, they had hardly any friends, and the Society was going from bad to worse; still, they had a President, and that President helped them. In the midst of their troubles, and when they were considering whether they should leave South Kensington or not, they were turned out! That was the darkest hour for their Society. They could not pay their rent, they had no home in London, and very few friends, but their President stuck to them. He was ready for the occasion, and under his wise and careful management the Society had gradually prospered, and it was now in a position which no other [horticultural] society in the world could boast of.

Now they were at the Drill Hall and at 117, Victoria St. They were wise to go there because they had nowhere else to go! He still held his old opinion that the Society ought to have a home of its own, and he hoped that some day such would be the case. He heartily congratulated the President on his wonderful knack in finding so good a Secretary as the Rev. Mr. WILKS, and he felt sure that under the guidance of such officers as they possessed the Society would flourish.

THE PRESIDENT, in response, said that Baron Schroder had referred to him in far too flattering terms. He well remembered the days about which the Baron had spoken, and he was bound to say that it was owing, in a large measure, to the Baron's hearty support that they were enabled to carry out the change of policy to which reference had been made. It was the duty of the Royal Horticultural Society to stick to horticulture, and from the moment the Council took up a position of determination to follow that course, it had not looked back. It was impossible for him, in responding to the toast, to give adequate utterance to the feeling of gratitude entertained by members of the Council towards the amateur and professional gardeners of the country for their support, as evidenced by the splendid collection of plants brought together in the Drill Hall that day. The President then quoted the following statement from the *Journal* of the Society:—"The Royal Horticultural Society has spent during the ninety-two years of its existence no less than £400,000. That it has made mistakes and wasted money its best friends will not deny; but it may confidently be asserted that it has done and is doing a good work which no other society could do—a good work of value to the community; and the introductions of the Society and the lessons it has taught have embellished the land, and smile on the visitor from every park and garden in the kingdom." He thought that fairly represented the work of the Society, which, he believed, had the cordial support of the horticulturists of this kingdom.

THE DISTRIBUTION OF MEDALS.

The company then adjourned to the Drill Hall, where a large number of persons had assembled to witness the interesting ceremony of presenting the Medals. The President made a few opening remarks, practically going over the ground he covered at the luncheon; and he called upon the Secretary, the Rev. Mr. Wilks, to read out the names of the recipients.

The medalists present were the following: Miss Jekyll, Messrs. J. G. Baker, F.R.S., Prof. Bayley Balfour, F.R.S., (Edinburgh), A. F. Barron (Chislewick), E. J. Beale, W. Boxall, W. Bull, Geo. Bunyard, F. W. Burbidge, M.A., W. Crump (Madresfield Court Gardens), R. Dean (Ealing), G. Dickson (Chester), Rev. H. H. D'Ombraun, C. T. Drury, H. J. Elwes, F.R.S., Geo. Gordon, Jno. Heal (Messrs. Jas. Veitch & Sons), Rev. Geo. Henslow, Dean Hole (Rochester), Sir Joseph Dalton Hooker, F.R.S., Rev. F. D. Horner, Jas. Hudson (Gunnersbury House Gardens), Peter Kay, John Laing, H. E. Milner, E. Molyneux, Geo. Monro, F. W. Moore (Glasnevin), Dr. Morris (Kew), Geo. Nicholson (Kew), Jas. O'Brien, G. Paul, T. F. Rivers, Baron Sir Henry Schroder, Jno. Seden, N. N. Sherwood, J. Smith (Mentmore), Martin H. Smith, W. Speed (Penryn), Arthur Sutton, Owen Thomas, H. Turner, G. F. Wilson, Jno. Wright, and Geo. Wythes.

Those not present were Miss Wilmott, Messrs. Peter Barr, Malcolm Dunn, Rev. Canon Ellacombe, Prof. Michael Foster, J. Fraser (Woodford), H. Herbet, C. Maries, Jas. McIndoe, W. Paul, the Hon. Walter Rothschild, F. Sander, W. Thompson, Ipswich; David Thomson (late of Drumlanrig), and Rev. C. Wolley Dod.

SOCIÉTÉ MYCOLOGIQUE DE FRANCE.

THE autumnal meetings of this Society were held from October 2 to 9, in Paris and its vicinity. They have acquired so wide a reputation for success and good management, that some members of the British Mycological Society determined this year to attend them. On Saturday, October 2, a party of four left London for Paris. It may as well be stated of whom this party consisted, and what their special objects in so doing were. In the first place, Mr. Rea, the secretary of the British Society was there with the avowed intention of learning the secret of the success of the French Society, as well as of mastering the French *Russulæ*; second, the writer, to find out what he could about the Potato-disease treatment, for it was at the meeting of the society ten years ago that he first heard of "Bouillie Bordelaise;" Miss Rose, of Worcester, to point the species found; and Miss Plowright, to do the interpreting.

The headquarters of the Society, 84, rue de Grenelle, at 9 A.M. on October 3, fairly enchanted the visitors by the highly interesting and beautiful collection of specimens it contained, all neatly arranged on white plates, with their names plainly written on white, red, or green labels, as the species were edible, poisonous, or of botanical interest only. We were received by M. Boudier, looking no older than he did ten years ago; and by M. Perrot, the indefatigable secretary. Of the number present, we saw MM. Patouillard, Bourquelot, Roze, Pelteoreau, Radais, Gaurin, Harlay, and many more whose names we did not catch; but before the meetings were over they had all done their best to make our visit enjoyable. The walls were decorated by paintings (of fungi, of course) by MM. Boudier, Pelteoreau and others, but our attraction was to the tables. *Polysaccum*, *Tulostoma granulosa*, *Favolus europæus*, *Montagnites* from the shores of the Mediterranean; *Guepinia helvelloides*, *Polyporus melaleucos* and *P. ovinus*, *Cortinari* Bulliardii, *Agaricus corydalina*, *A. geoginus*, *A. Eryngii*, *A. madidus*, all of which are either absent from, or exceedingly rare in Great Britain. The English visitors lost no time in settling down to work, sketching, making notes, and reading up. In fact, so interested was the British secretary that rumour says he was so busy that he only spoke six times during the two days the exhibition was open; while the writer is credited with asking 600 questions, not only through the medium of the official interpreter, but, failing her, of any unfortunate passer-by, or, as a last resource, on a half sheet of note-paper, the backs of old envelopes, and what not.

October 5 and 6 were spent in excursions in the forest of Compiègne, the necessary arrangement for sleeping, eating, driving, &c., being made by the energetic secretary, M. Perrot, who went down the day before for that purpose. Here we found *Inocybe maculata*, *Polyporus umbellatus*, *Clavaria fennica*, *Tricholoma immundus*. On Wednesday we had *déjeuner* in a room built in the forest at Pierrefonds for the late Empress; there were found *Tuber bituminatum*, *Agaricus junquillea*, *Godey*, *griseo-cana*, *Hydnum amicum*, &c.

October 7 was spent in Paris, a quiet day, so as to allow time for the study of our finds. At 2 P.M. a meeting of the society was held at which the writer presided, having had the honour done him of being elected honorary president for the *session extraordinaire*. Various specimens were exhibited, and several communications of great interest made, principally on fungus disease of plants, notably, one on black rot in grapes; and another on a disease of the roots of Chestnut trees.

October 8 was spent in an excursion to the forest of Herblay. No sooner had we arrived than the beautiful *Lycoperdon villatum* was gathered, and shortly after a whole bed of *Geaster hygrometricus* was encountered, *Helvella pithyophila*, *Lactarius scrobiculatus*, and the beautiful *Cortinarius rufo-olivaceus* were amongst the finds; but a frost the previous night had done irreparable damage to the larger fungi. In France ladies seldom take part in such out-door scrambles as fungus hunters undertake, but two ladies accompanied this excursion. This we took to be a delicate compliment to our English ladies, who had hitherto been rather "out of it" amongst so many gentlemen. Our interchange of ideas was this day greatly facilitated by the kindness of M. Philippe de Vilmorin.

The forest of Carnelle was to have been visited on October 9, but owing to the frost the British mycologists decided "to leave it until next time." This much is certain (1) France is a good country for fungi. (2) The French mycologists are exceedingly kind and thoughtful hosts, they made every effort to make our visit profitable and enjoyable; and I fear, if the truth must be told, to take them all round, they know a great deal more about fungi than we do. *Charles B. Plowright, M.D., King's Lynn, Oct. 16, 1897.*

MANCHESTER AND NORTH OF ENGLAND ORCHID.

OCTOBER 21.—Present: J. W. Thompson, of Walton Grange, Staffordshire, in the chair; along with Messrs. Geo. Shorland-Ball (Vice-Chairman), W. Stevens, A. Warburton, G. W.

Law-Schofield, H. Greenwood, E. J. Sidebotham, D. B. Rappart, R. Johnson, John Cypher, John Leemann, Sam. Gratrix, Jas. Anderson, and W. A. Gent, Hon. Sec.

This was by far the largest show yet held, some of the choicest varieties in cultivation being exhibited. It is impracticable to notice the whole of the exhibits, and some names of exhibitors and some good things must, therefore, be passed over. There were about sixty different plants brought up for adjudication, and out of these no fewer than eight received awards of First-class Certificates, and fifteen received Awards of Merit.

Undoubtedly the greatest novelty was *Cattleya labiata* Petersiana, exhibited by ALBERT WARBURTON, Esq., Vine House, Haslingden (Mr. Tom Lofthouse, gr.). The colours are vivid, and of remarkable glossiness; without the slightest shading in either the petals, sepals, or labellum, the colour being of a deep cardinal-red throughout. It received a First-class Certificate. One of the members proposing a small Gold Medal for the novelty, but this was left over for consideration.

The next important plant, which was shown before the Royal Horticultural Society in London some years ago, and received the highest honours, was the plant and variety of *Cattleya Hardyana* (First-class Certificate). This consists of a portion of the famous plant first brought to light by the late George Hardy, and was disposed of when that collection was dispersed. It is at the present time in the possession of T. Statter, Esq., Stand Hall, and as shown was a picture of beauty. The numerous varieties of the so-called *Hardyana* from an orchidist's point of view, cannot compare with this variety. The flowers are large and of great substance, well formed, with the segments flushed; the labellum is of a beautiful crimson, with a flushed edge; the spots adorning each side of the extremity of the column are white, and the yellow surrounding the white is conspicuous, as are also the lines of the same tint traversing the epichilium; and the whole a grand flower. Mr. Johnson took also a First-class Certificate for *Cattleya aurea* Johnsoni, one of the most distinct of the aurea section. It is a curious combination of colours which Mr. Johnson fears will not remain constant, and forms another example of how easily buyers and sellers can arrive in the law courts.

WM. LAW-SCHOFIELD, Esq., had two First-class Certificates for *Cypripedium Lawrebel* and *C. Lawrenceanum* Hyeaen, both acquisitions: the former having a standard of surpassing brilliancy of either of its parents; the other, which bears the name of Frances Marie, is one of the best of this cross, the standard being large, and the colours and lines clear.

H. H. BOLTON, Esq., Heightside, Newchurch (Mr. T. Eastman, gr.), had a *Cattleya labiata* with white segments, and a lip slightly stained with puce, which I described in the *Gardener's Chronicle* as *C. labiata* Ballie, and which is practically the same as *C. l. Measuresiae*. Both gentlemen agree to have it named *C. labiata* Elsie, after Mr. Bolton's daughter. It appears likely to improve under cultivation.

SAMUEL GRATRIX, Esq., West Point, Whalley Range (Mr. McLeod, gr.), received a First-class Certificate for *Cattleya labiata* Sam. Gratrix and *Cypripedium* insignis, var. *Sanderi*. The *Cattleya* is of the pure and white in regard to the petals and sepals, of good substance; the labellum white with a cerise-coloured blotch, having pale flushed edging. It is a flattish flower of fine form, and distinct. The *Cypripedium* is well known and much appreciated, and this example was as good, if not better, than the famous "Baron's variety."

JOHN LEEMANN, Esq., West Bank House, Heaton-Mersey (Mr. Edge, gr.), received a First-class Certificate for *Cattleya Hardyana* of quite a different type from the first one flowered at Pickering Lodge. It is of deep colour, and one in which *C. gigas* and the deeper tints of *aurea* are seen, but it is lacking the beauty of the other.

Among the Awards of Merit, Mr. STATTER had the red *Cypripedium Locanum* (Memoria Moensii), and the large and clear *C. insignis* Statteriana.

WM. THOMPSON, Esq., of Walton Grange (Mr. Stevens, gr.), had *Cypripedium Charlesworthi* roscum and *C. Juno*. He had also a fine large-flowered *Vanda Kimballiana*, larger and brighter than the normal flower, for which Mr. Stevens received a Cultural Commendation. The chairman of the Society also received the 2nd honours for *Odontoglossum crispum* bellissimum, a very large flower, with heavy blotches of sienna-brown; along with a Cultural Commendation for a so-called *Cypripedium Spicerianum* magnificum with twenty-one good flowers upon it—but it is not magnificent. G. LAW-SCHOFIELD, Esq., Rawtenstall (Mr. Schill, gr.), had 2nd honours for *Laelia purpurata* Anna Louise, and for *Cattleya* x *Mantini*.

HUGH LOW & CO., London, received awards for several *Cypripediums*, the most distinct of which was *C. Swanianum* virescens; this firm also put up *Laelia* prestans alba, bearing a good flower on a small plant (Award of Merit).

WM. C. CLARKE, Esq., Sefton Park, Liverpool (Mr. Jones, gr.), had a showy lot, but the only one which was noticed was a finely grown, good variety of *Cypripedium* insignis, called Col. Clarke, which received a Cultural Commendation.

E. J. SIDEBOTHAM, Esq., Erisdene, Bowden (Mr. Shiner, gr.), had *Laelia Perrini* in fine colour and in good flower; and *Cattleya maxima*, which was a remarkably distinct species.

F. SANDER & CO., St. Albans, had an Award of Merit for an *Odontoglossum grande*, called West Point—a meaningless name. It is very dull in colour, and resembles a bad *O. Schleperianum*. *Cypripedium Ernesti* is too like *Youngianum*—it was awarded 2nd honours, however. We are

getting too many of that sort, and it might be well to pass them by.

MR. LEEMANN showed *Cypripedium Harrisianum* called *superbum*—a good thing; and the pretty *Epidendrum Wallisianum*, which the committee requested should be brought up again.

The groups were exceedingly showy, but no awards were made. They came from the chairman, HUGH LOW & CO., and CHARLES WORTH & CO. The finest exhibits were in cut flowers, Mr. JOHNSON showing *C. aurea*, marked in an abnormal manner; and Mr. STEVENS a fine *Laelia Perrini* alba—it was a pity that he had not brought the plant as well.

After the awards were made, the committee resolved, proposed by Mr. Ball, seconded by Mr. Schofield, and unanimously carried, "That in awarding First-class Certificates, the committee shall be guided entirely by the merits of the flower brought before them, without regard to the fact that the same or a similar variety may have already received a First-class Certificate, but no member shall receive more than one First-class Certificate for the same plant."

Also proposed by Mr. Ball, seconded by Mr. Johnson, and unanimously carried, "That from this date no First-class Certificate be awarded to cut blooms, except the committee are of opinion that it would have been risky to bring the plant from which such blooms have been taken."

Proposed by Mr. G. Shorland-Ball, seconded by Mr. Stevens, and carried, "That rule 4 be expunged from the rules of the society, and the following rule be inserted:—4. The annual subscription for gardeners shall be half a guinea, and in all other cases one guinea." J. A.

THE ROYAL SCOTTISH ARBORICULTURAL AT DOLPHINTON.

OCTOBER 23. — By invitation of the venerable owner, JOHN ORD MACKENZIE, Esq., W.S., about sixty members of the Scottish Arboricultural Society visited, on the above date, Dolphinton, a charming place embowered in trees and environed by hills. The train left the Waverley station at 10.15 A.M., and returned at 4.55 P.M., thus furnishing time for the visitors to explore the sylvicultural treasures of the woods, glens, park, and garden.

Mr. Mackenzie met and gave his guests a hearty welcome at the station; Sir James Fergusson, of Spittalhaugh, joined the party at Linton, and was indefatigable throughout the day in assisting his neighbours, Mr. and Mrs. Mackenzie, to unfold the sylvan treasures, and treat of the associations of this well-wooded estate. It soon became apparent that Mrs. Mackenzie was by no means the least accomplished of these three arboriculturists. The first halt was called at the bridge where the water divides into two parts, one part finding its way to the Tweed, and part to the Clyde. It was said that salmon occasionally pass here from one river to the other.

It may be stated here that the parish of Dolphinton is situated in the eastern division of Lunarkshire. It is bounded on the north by the parish of Dunsore, on the west by Balston, and on the south and south-east by Kirkcudbright, Linton, and Peeblesshire. It is also intersected by the rocks from Biggar to Edinburgh, and Peebles to Linton, and dominated to a great extent by the Blue Hill of Dolphinton, some 1500 feet above the level of the sea, and which may be described as one of the links of the mountain-chain which binds the island from Stobbles Head to Allis Craig.

Another prominent feature rising more like an artificial mound than a natural mountain—the Bromilow, so well known in the history of our commercial supremacy on the Clyde, is also within sight, barring fogs, of the Black Hill of Dolphinton.

Within a short distance of the new lodge on the other side of the house, no fewer than five parishes meet on the estate, viz., Kirkcudbright, Watton, Skilling, Biggar, Dolphinton; the general elevation of the parish and estate being some 800 feet above the level of the sea. A curious record is placed on the steps of the front door of the mansion to the effect that this stone is on a level with the top of Arthur's seat at Edinburgh. But though thus highly elevated, and the soil mostly a sandy loam, or a dry, friable earth, yet so skilfully has the estate been managed by the present proprietor and his father, who began a good deal of the planting, that the physical features of this district have been greatly softened and improved, and the local climate sensibly ameliorated through the shelter and functions of the rising plantations.

The last visit of the Arboricultural Society here was in 1880; and those who were present on that occasion were loud in their praise of the growth and progress the trees had made in the last seventeen years. But before the vigorous work of reclamation and improvement began—some seventy years since—on this estate of some 3000 acres, it was largely a barren waste. Of course, a few of the fine old Beeches, Elms, Ashes, Sycamores, Oaks, Limes, and Larches, that sweep up the park to the front door, and tower away majestically in various directions, belong to an earlier period, and must be more than a hundred years old. The old Larches, too, look remarkably healthy; while the young ones mixed with the Scots Firs further up the hill-sides, are not so healthy as the Scots. The Douglas Fir and other exotic Conifers are, however, the great feature of Dolphinton. Near to the houses one fine Douglas fir over 9 feet some 3 feet from the ground. Others almost as large were found in various parts of the wood or dell; and a fine group planted as seeds by the Misses

Mackenzie at Christmas, 1864, had made great progress. Mr. Mackenzie was also specially proud of a scarlet Oak, *Quercus coccinea*, which, however, had been somewhat severely cut by frost.

After passing through the well cropped gardens, and paying a visit to the greenhouses, &c., the visitors were mustered by their hosts to a most sumptuous lunch. After a hearty vote of thanks, signing their names in Mr. Mackenzie's book, and being photographed, the journey through the plantations was resumed. Here trees and avenues of the Douglas Fir, *Abies magnifica*, *A. nobilis*, *Picea Albertiana*, *P. nigra*, *P. orientalis*, *P. Menziesii*, the Lawson Cypress in many forms, the Japanese and the Giant Cypress, were found; also heaps upon heaps of *Rhododendrons* in the most robust health, *Spiraea* of sorts, Dog-wood and Spindle trees, in bright foliage.

In an open place in the dell, surrounded with a prodigality of silvan beauty, one of the most interesting functions of the day was performed. A nice thriving plant of the Himalayan Spruce, *Picea Morinda*, presented to the society by Mr. Foreman, nurseryman, Eskbank, was planted by Mrs. Mackenzie, assisted by her husband and the head forester, who has been on the estate for some sixty years, and the head gardener.

With three hearty cheers, the visitors took another turn through the old kirkyard, where a Sycamore tree with a girth of 15 feet was found; past a lake near a villa on the estate, with lines of beauty and grace, said to have been designed by Mr. Mackenzie, and so over and away through more rising woods, and across hills flooded with sunshine, to the station, after one of the most profitable and pleasant outings ever spent by the society.

The three W's of Dolphinton are the woods, the water, the walks. As to the woods, only a few more touches were needed to bring them into line with brown October. As to water, one lovely lake was noted, and its ezy, curling, pond provided with welcome shelter from the blasts. A third lake was seen in the hanging plantation above the mansion, from whence the water is allowed to fall by gravity to storage-tanks, whence it is distributed by means of pipes. A "water-house," sweet and tempting, with glazed tiles as a floor, &c. As to the walks, most of them are narrow, nicely curved, and sheltered in such a way that they are warm even in the coldest weather, and revealing many a peep of a lovely landscape. D. T. F., October 25, 1897.

NATIONAL CHRYSANTHEMUM.

OCTOBER 25. — A considerable number of blooms was staged on this occasion, and the committee were engaged for some time in examining them. It is due to the committee it should be stated, they set up a high standard now so many new varieties are coming to the fore.

MR. W. J. GODFREY sent from Exmouth a collection comprising nearly twenty new varieties, and First-class Certificates were awarded to the following new varieties:—*Malan's Philippe Rivoire*, a large white Japanese, broad petals, somewhat reflexing—a very fine exhibition variety; *Elis Curtis*, a large, full, bright yellow Japanese, in the way of *Boule d'Or*, not quite so deep in colour—a grand exhibition variety; and *Lady Ridgway*, a very large, broad-petalled, incurved Japanese, lilac-purple on the surface, with a pale amber reverse, much incurved, and decidedly distinct. In addition, Mr. Godfrey had *Werther*, *George Gover*, and others, of fine quality; also, three new incurved varieties: *King of Yellows*, *Topaz Orientale*, pale primrose-yellow and *Ma Perfection*, a promising white.

From Mr. C. SHAW, Fooks Cray, Kent, came *Elise Teichmann*, a white Japanese, which has been seen in finer condition than that in which it was shown on this occasion; but of its value and beauty there can be no doubt.

From Messrs. H. CANNELL & SONS, Swanley, came *Lady Hanham*, a sport from *Charles Davis*, which was a sport from *Vivand Morel*, like its ancestor, of fine shape; the colour delicate pink, with pale citron centre, but apparently liable to come variegated in character (First-class Certificate). A very delicate soft pink incurved Japanese named *N. C. S. Jubilee* is of a very promising character, but failed on this occasion to secure a majority of votes for a Certificate. *Souvenir de Molines*, pale reddish chestnut and orange, but a somewhat variable variety, is likely to prove useful.

MR. W. WELLS, Earlswood, Redhill, sent a number of new varieties, chief among them *G. J. Warren*, a pale yellow sport from *Madame Carnot*, which appears to possess all the good qualities of the type; and Mrs. G. W. Palmer, a sport from Mrs. C. H. Payne, the colour ruby amaranth, with a buff reverse, certainly a promising flower; this also came from Messrs. GODFREY and NORMAN DAVIS. From Mr. R. OWEN, Maidenhead, came several new varieties, chief among them *reflexed J. E. Lager*, a pale yellow variety in the way of *Dorothy Gibson*, but thought not to be so good.

MESSRS. J. R. PEARSON & SONS, Chilwell, Notts, sent *J. Leadbetter*, a sport from *Madame Edward Ray*, deep orange with yellow centre, a flower which is likely to be next better developed.

From Mr. NORMAN DAVIS, Framfield, came an exquisite incurved Japanese, Mrs. S. C. Probyn, delicate blush-pink deepening to soft pink, large, full, broad-petalled, and very fine (First-class Certificate). Among some varieties recommended for market work was *Pride of the Market*, deep gold, with a surface of pale reddish-brown, very bright, and showy (First-class Certificate). Another market variety, white, something in the way of a small *Avalanche*, failed to secure this award, though very pleasing in shape and appearance.

FIG. 98.—FORDE ABBEY, CHARD. (SEE P. 322.)

tern station of Chard Junction may be thin a mile and a half. front of the Abbey is just 100 yards long. its northern side the chapel, with the mitories, well preserved, behind. Next come the cloisters, with the old refectory

tapestry, copies of the famous cartoons of Raphael, representing ancient historical and biblical scenes. It is reputed that a former owner, Mr. Francis Gwyn, refused the offer of £30,000 from Empress Catherine of Russia for these grand masterpieces. The original founders of the Abbey were the Cistercian Order of

Various persons possessed the Abbey, including Mr. Francis Gwyn, a distinguished man of his day, whose son, John Francis Gwyn, was even more so, and it is stated that in 1815 he let the Abbey to the famous Jeremy Bentham, who there wrote some of his famous philosophical works, and during whose res-

FIG. 95.—THE CLOISTERS, FORDE ABBEY, CHARD. (SEE P. 312.)

This fine room, which originally ran to eight of the Abbey, is now divided by the old features have been religiously Beyond the cloisters come the noble orch and hall, and beyond the living rooms, art from many most interesting monastic logical features, are some grand pieces of

Monks, and the date early in the twelfth century. In 1539, on the dissolution of the monasteries, the Abbey became the property of King Henry VIII., who leased it and the adjoining lands to Richard Pollard, at the rent of £49 6s. 6d. This figure shows something of the relative values of estates now, and what they were at the time of the Reformation.

dence was visited, amongst others, by Sir Samuel Romilly, who wrote a glowing description of the "magnificent and beautiful palace" in which he found his friend the philosopher residing. In 1846 it passed out of the possession of G. F. W. Mills, Esq., of Bristol, into that of Mrs. Bertram Evans, and is now the property of her son, Mr. W. H. Evans,

who happily shows himself to be a liberal as well as an enthusiastic admirer and protector of his charming and ancient home.

In embellishing the Abbey, the art of the gardener has been lovingly utilised, and beautiful climbers on the walls, flowers, and lawns, with broad terrace-walks, extensive hardy flower-borders, broad, grassy expanses of smooth lawn, noble trees, and wide-spreading shrubberies, enrich the southern or park side of the Abbey; whilst behind are the kitchen gardens and glass-houses. Mr. J. Crook, a very able, energetic—indeed, an enthusiastic gardener—is here the presiding spirit, and well does he seek to associate all that is decorative with the building, which forms so interesting a central figure. Whilst there is ample evidence of ability in cropping and in production, there is an absence of that primness that may be all very well in association with newness, but would be sadly out of keeping with so ancient a place. The very utmost is made of good trees and shrubs, of glades and walks, of foliage and flowers, in all directions; but there is no aping of the modern styles one sees elsewhere to repletion. Vegetables and fruits are well and abundantly grown, and every inch of space in an all too limited area is fully utilised. Almost the only attempt at modernising anything is found here and there in the pleasure-grounds, where—and most excusably—effort has been made to introduce coloration, especially in foliage, but still so toned as in no sense to seem offensive. Where it was possible to introduce a nice foliage or flowering tree or shrub that would in due season give some special coloration, especially as a rather distant object, that has been done—and very acceptably too, where there had so long been so great a wealth of green foliage and herbage as here. Of flowering and foliage material, *Pyrus Malus floribunda* and *spectabilis*, *Robinia Decaisneana*, *Bessoniata*, *bispida*, and *sempervirens*, *Aralia spinosa*, *Dimorphanthus mandshuricus*, *Pavia macrostachya*, various coloured double and single thorns, the Scotch Broom, *Spiræa arifolia*, *Lindleyana*, and *callosa*, *Berberis vulgaris* and *Darwini*, *Catalpa syringæfolia*, *Pawlonia imperialis*, *Philadelphus grandiflorus*, Red Horse-Chestnut, *Prunus Pissardi*, *Acer Negundo variegatum*, numerous Japanese Maples, the pretty fern-leaf Beech, also the purple ditto, and purple Hazel, cut-leaved Alder, golden Alder, *Rhus Cotinus*, *Liquidambar*, with berried *Pyruses*, and many other similar things, flowering and foliage, tell of the efforts made to give colour in respective seasons. The bridge leading over the moat to the gardens still exists, the balustrades being covered with Ivy, and on that grows luxuriantly such old climbing-Roses as *Félicité-Perpétue* and the Dundee Rambler. Altogether, the place is full of interest. The pictures of the Abbey-front and the cloisters (figs. 95, 98), are from photographs taken by Mr. Higgins, of Chard. A. D.

TREES AND SHRUBS.

THE WEEPING SILVER FIR (ABIES PECTINATA PENDULA).

THIS rare variety of our common Silver Fir is at once the most remarkable of the several forms of this well-known tree. Neither in the *Kew Hand-list of Conifers*, nor in the *Pinetum Danicum* (where varieties have received special attention) is the Weeping Silver Fir referred to. [It is in *Masters' List of Conifers*, in *Gordon's*, and in *Bumser's Enumeration*.] *Gordon*, in his *Pinetum*, says that *P. pectinata pendula* (Godefroy) is of French origin, with the branches and twigs drooping. Whether or not this is the particular variety at present under notice, matters little; one thing is certain, that the specimen which furnished material for this note, is not only well worthy of the name, but is, in all probability, the largest tree of its kind (if, indeed, there be any others, which I have not heard of) in the British Isles. It is growing in rather an obscure position hard by the lawn at Emmetts, a beautifully situated property on Ide

Hill, at Sevenoaks, and in company with giant specimens of *Thuja gigantea*, hort., *Abies nobilis*, and hosts of other Conifers. The tree is 42 ft. high, the branches being so pendulous that no part of their spread exceeds 4 feet in diameter, while they hang down parallel to the main stem for from 3 to 5 feet in length. The leaves are much shorter than those of the species, rarely exceeding from $\frac{1}{2}$ to $\frac{3}{4}$ of an inch long, but are characterised by the same silvery bands on the under and deep green on the upper surfaces. Curious to say, the tree does not appear to be a grafted specimen—at least, I could discover no traces of grafting. A. D. Webster.

THE MANGOSTEEN.

(See figs. 96, 97.)

THANKS to the courtesy of the authorities at Kew, we have been enabled to taste a ripe fruit of the Mangosteen grown in Trinidad, and sent home by Mr. Hart. The fruit is of the size of a small Orange, leathery, purple, with a thick green four to five leaved calyx at the base, and a sessile four to five lobed stigma at the top, the stigmatic lobes long club-shaped, flattened. Each seed is enveloped in a white or pinkish juicy pulp, which has a very delicate and agreeable flavour, though it does not here bear out the eulogistic verdict of travellers. The thick leathery rind offers ample protection, so that its importation should be easy. In 1875, similar fruits were sent us by Mr. Prestoe, also from Trinidad. The first time the tree fruited in this country was at Sion (see our volume for 1855, and the plate in the *Botanical Magazine*, t. 4847).

THE ROSARY.

ROSES, WHAT TO PLANT, AND HOW TO DO IT.

THE all-absorbing question amongst Rose-growers is now—How am I to re-arrange my Rose-garden? The answer to this involves so many questions. "On what stocks do you wish to have your plants growing?" "Do you intend to grow for exhibition, or for the home adornment of your garden?" "Have you walls or trellises on which you can grow climbing-Roses?" And perhaps, most important of all, "What is the character of your soil and climate?" One would think that now-a-days there was no longer room for mis-statement or incorrectness in classifying Roses, yet more than once lately I have seen such incorrectness as that of classing *Souvenir de la Malmaison* amongst Teas. Surely writers ought to be a little more careful, and avoid such mistakes as this. Perhaps one of the most important questions for a Rose-grower is, On what stocks am I to have my Roses? "Oh! have nothing to say to stocks," someone says; "grow Roses on their own roots, and you will be on the right way to success." In connection with this, I read the other day a remarkable statement, apparently coming from authority, saying there was great difficulty about obtaining them, because nurserymen were more anxious to get rid of their standards than to take the trouble of striking Roses. Now, I know most of the large Rose nurseries, and my opinion is, that the standards form a very small portion of their stock, and that there is always a sufficient demand for them, and that quarters where they are grown are almost empty as the autumn advances; while another writer would sweep out of existence altogether except for maiden blooms, the Manetti stock, which has done more to advance the culture of the Rose than any other, and which, notwithstanding the denunciation to which I have alluded, is likely to survive for many a long day. There are three stocks which are most largely used now—the Manetti, the seedling Briar, and the Briar cutting. The manner in which Roses are budded adds another element of success in their growing, namely, that of budding them very low down, so that after a while there is a double source of strength, the

stock and the scion, which has now made roots for itself, and which accepting the services of its foster mother, starts also on its own account. One argument put forward in favour of Roses on their roots is, that they are so much longer lived—this is, I think, very questionable. I have, for instance, two plants budded on the Manetti in my garden which are between forty and fifty years old, and which give me a good crop of blooms every autumn; they are the fine old favourite, *Souvenir de la Malmaison*. I have also plants of climbing Roses, such as *Rêve d'Or* and *Madame Berard*, budded on the seedling Briar, which are between twenty and thirty years old. When people advocate the abolition of the Manetti stock, they seem to forget how easily it is struck and worked. The seedling Briar is very often a difficult matter for the budder, as the stem is so small; and this is probably one of the reasons that has led of late years to the introduction of the Briar cutting; and with these three stocks I think growers may be very well content—unless, indeed, they are exhibitors, amongst whom there remains a strong persuasion that there is no stock from which you can get such good Tea Roses for exhibition as on the standard or half-standard woodland Briar. It is strange that it should be so, for every severe winter makes sad havoc amongst them, not only here but in France; for it should be borne in mind that the northern districts of France suffer severely from cold. I suppose that Brie Comte Robert, which was the nursery for Roses not only for France but for foreign countries, has never recovered the disastrous winter of 1870, when every standard Rose in the district was killed—and there is no remedy for such a disaster; you can mulch and otherwise protect your dwarf Roses, and, however they seem to be cut down, they will spring up from the underground stems, but the Briar-Rose, when the top is killed, has no power of recovery. It is recorded of a well-known amateur who was just beginning his Rose-growing, that he once went to see the garden of the president of the National Rose Society in the midland counties, and came away with the conviction which he published to the world that the Roses were all dead; he was told, however, if he came again in the following spring, he would have a different tale to tell. Moreover, Roses are not so easily struck from cuttings. There are some kinds which seem positively to reject the plan; besides, if a Rose has a delicate constitution, it is much more likely to succumb on its own roots than when it is budded on a moderately strong stock which may help it. On the whole, then, I do not think that Rose-growers need trouble themselves about having own-root Roses. I would therefore recommend that all hybrid perpetuals of strong and vigorous growth, such as *Etienné Levet*, *Margaret Dickson*, and *Magna Charta* should be obtained on the Manetti, while all Tea-scented Roses and Noisettes should be procured on either a seedling Briar, or a Briar cutting. There are, it is true, some Tea-scented Roses of very vigorous growth, such as *Marie Van Houtte*, which do not object to the Manetti stock, but I think it would be safest to have all Tea-Roses as I have said on Briar. With regard to the so-called Hybrid Teas, there are some which approach very closely to the Teas, such as *Kaiserin Augusta Victoria*, and these I think should be grown upon the Briar, either seedling or cutting; while others, such as *Clara Watson*, which approach more nearly to the H.P.s, may be grown on the Manetti—but while saying this, I readily acknowledge that all Roses take to the Briar very kindly, and probably in course of time it will be the most generally used stock.

There are two points on which rosarians generally, I think, ought to put down their foot; one is, to have no Rose which is described in catalogues as moderate or difficult to grow. I know that this will exclude some very beautiful Roses, but as long as we are content to keep on growing these almost as annuals, we shall not find Rose-growers anxious to supply us with better growing kinds; and what is the use of growing a Rose that will give you a few blooms in the first season and then dwindle away? "What, then," it may be said, "am I to give up growing *Horace Vernet*?" "Yes, unquestionably, unless you are an exhibitor."

It is heartbreaking to see the after-history of this grand Rose. There are now in almost every variety of colour Roses of good constitution and habit, so that we may dispense with these weakly and uncertain growers. The other point is a somewhat more difficult one, namely, that we ought to avoid all scentless Roses. Since Victor Verdier was sent out, there has been a series of Roses without perfume owing their origin to this Rose, some of which are very beautiful, and which Rose-growers would be very unwilling to give up. There is no greater favourite than Baroness Rothschild, yet it has not a trace of perfume, and so many of the lighter-coloured variety in the same series are very disappointing in this respect; nor do we require what I may call a deteriorated tea-scent or the faint perfume of the Bourbons. What we really do want is, Roses with the true attar of Rose-scent, or the delightful perfume of the old Provence Rose, and I would go so far in this direction as not to award any honour to Roses deficient in perfume. This, perhaps, may lead raisers of seedling Roses to endeavour to give us some more brilliant colours, because, I think perfume and colour go very much together. The idea of a scentless Rose never occurred to our old

persons will welcome it on that account. Another flower which has increased in favour the last year or two is Clio, sent out by Messrs. William Paul & Son; it is of flesh colour, shaded with rosy pink in the centre, and is another valuable kind for pot culture. *Wild Rose.*

(To be continued.)

CULTURAL MEMORANDA.

CLERODENDRON FALLAX.

THIS species is one of the very finest of the genus, and is unsurpassed for the decoration of the plant-stoves or warm conservatories. A native of Java, it produces large cordate-ovate leaves of a dark green colour. The flowers, bright scarlet, are borne on erect panicles, thrown up well above the foliage. Clerodendrons delight in a moist humid atmosphere during growth, but need to be rested when they have ceased to flower in the autumn, by exposing the plants to the sun and air, and gradually lessening the amount of water given them until the leaves are quite ripe and fall off, the wood will become perfectly ripened. The plants may then be placed under the

nately with clear water. Clerodendron fallax may be propagated either from cuttings or seed. Cuttings should be made from pieces of the old wood, and these may be inserted round the sides of a 48-size pot in sandy soil, and plunged in the propagating-pit up to the rim; or the young shoots may be taken off with a heel of the old wood attached, and treated in the same way.

To raise plants from seeds, sow in February, and plunge the pots or pans into a strong bottom-heat. When the seedlings are large enough, pot them off, and keep them growing freely. Such plants may be bloomed in quite small pots, and they are then very effective for house and table decoration. *H. T. M., Stoneleigh.*

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Bayleigh, Essex.

Pruning and Training Wall Trees.—In the present month, the pruning and training of wall-trees may be begun, the Morello Cherry being the first taken, and the last the Peach and Nectarine in January and February. The Morello Cherry requires merely to

FIG. 96.—THE MANGOSTEEN (*GARCINIA MANGOSTANA*). (SEE P. 321.)

writers, whether in poetry or prose, and certainly with the great improvement that has taken place in other respects in the flower, we ought to look, I will not say to improvement, for that perhaps may be difficult, but to maintaining these most desirable qualities in our modern flowers; and I do think that, where the blood of the old Damask enters into our Roses, there we have a good perfume. In deciding upon what Roses shall be added to our collections, I deal mostly with those of recent introduction. I will not say absolutely new, but comparatively so.

In the Hybrid Perpetual class of exhibition Roses there are but few novelties. The most brilliant coloured flower is the last of Mr. Bennett's Roses, Captain Haywood: it was not looked upon with much favour when first shown, being considered too thin, but it has considerably improved since then; it is admirably adapted for pot culture and forcing. The flower as shown by Mr. George Mount, at the Drill Hall, in the earlier part of the year, testifies to its usefulness in this respect. Mrs. Sharman Crawford and Helen Keller, two of Messrs. Dicksons' latest additions, are very beautifully pink-coloured flowers, and may safely be added to any collection. Messrs. Paul & Sons' Rose, Alan Cheales, is a fine flower, bearing a good name; its colour is novel, and many

stage in the stove, in such a position that they will receive no drip, and yet where they are prevented from remaining excessively dry.

Early in the month of March shake the plants out from the old soil, and at the same time shortening the strongest roots. Then prune the plants back to within two or three buds of the old wood, and pot them into as small pots as they can be conveniently put into. For a potting compost, use fibrous loam two parts, peat one part, and dry cow-manure one part, with an addition of crushed bones, charcoal, and silver-sand.

When potted, plunge the plants in a bed of fermenting material, the temperature of which should range from 75° to 80°. Water with care until such times as the roots have got well into the new soil, and then more copiously. Moisten the paths and stages frequently by sprinkling. As the plants progress in growth, maintain a temperature of from 65° to 70°, ventilating freely on all favourable occasions, and as the plants require it shift them into larger pots. When they have become well established in these larger pots, afford them liquid-manure freely, which may be prepared by placing in a sack some sheep or cow-dung, with soot added, and immersing it in a tub of rain-water. Allow it to remain for a week before using, when it may be applied to the plants alter-

have its shoots thinned out, so that they may be trained-in about 2 to 4 inches apart, leaving as many young ones as will make a well-balanced tree; cutting back the old, bare, and fruitless shoots to their base, and fore-right shoots to one wood-bud. Strong growths likely, if left, to starve others, should be removed, or where it can be done, bent downwards for a season or two. The only permissible form for the Morello as a wall-tree is the fan, in which, as is well known to gardeners, the main branches radiate from the centre, like spokes in a wheel, the minor shoots following in the same direction. In the case of young trees of last year's planting which have made uniformly strong growths, bend the unpruned shoots towards the ground, and secure them to the wall with nails and shreds in that position, the bend in the shoots starting from the point at which the lowest of the new shoots are required, say, 4 or 5 inches from the base. The check thus given to the flow of the sap will cause a sufficient number of wood-buds to push from the bent shoots as to form a fan-shaped head in the second year after planting. These remarks are equally applicable to other kinds of wall-trees, including trees planted during the present season. As soon as the buds nearest the base of the shoots bent down have pushed into growth, the nails must be drawn, the main shoots spread out at the proper distances apart and secured thereto, the young shoots being trained regularly over the intervening spaces. In pruning Plums, Pears, and

sweet Cherries, the summer growth should be cut back to a wood-bud close to the base of the shoots, and the older fruiting spurs where standing very close should be thinned out, as crowding of the fruit-spurs and shoots on any fruit-tree or bush is an evil to be avoided. A space of from 6 to 8 inches should be given to the main branches of Plums and Cherries, and 9 to 12 inches to those of the Pear, unless fan-trained, when they will be further apart at the ends.

Insect Attacks.—Every sort of fruit-tree being subject to the attacks by insects of some kind, the cultivator must carefully examine each tree when pruning it, and those which are infested in ever so small degree with white or brown-scale or thrips, should be dressed with a mixture, consisting of about 6 oz. of soft-soap dissolved in a gallon of water, adding to this a wine-glassful of petroleum, a 3-inch potful of flowers-of-sulphur, and a like quantity of fresh soot, and sufficient clay to give the mixture the consistency of thick paint, stirring this well before applying it to the infested trees with a stiff brush. The mixture should be dabbed into every crevice, and especially about the fruit-spurs, taking care to coat over every shoot and branch—especially on the wall-side of the branches. Afterwards secure the branches loosely together, and suspend them at a distance from the face of the wall for a week or two before training them to the wall. In preparing this dressing, it is advisable to make enough at one time to meet all requirements, out-of-doors as well as under glass. Now is the time to prevent by means of grease bands the ascent of the winter moth.

THE KITCHEN GARDEN.

By W. FORD, Gardener, Highclere Castle, Newbury.

Peas for Autumn Sowing.—The sowing of Peas in the open for early cropping should take place in the first or, at the latest, the second week in this month. The varieties to sow are the round-seeded early podders; and as in the early summer a few days sooner or later in obtaining a dish of Peas is usually deemed by gardeners a matter of importance, a little more trouble taken in the matter of sowing, &c., will not be thrown away. The situation of the ground to be sown should face the south, and be sheltered by walls or tall hedges on the north and east. The soil should be light rather than heavy; and should the staple be tenacious, charred garden refuse, old potting soil, and the decayed refuse of the garden which has been once or twice turned and once heavily limed, may be trenched into the soil. Some light soil should be provided for covering the seed to the depth of 2 inches. The seed should be in larger quantities than is called for in spring sowings, and the drills should be drawn with the hoe of a width of 4 inches at the bottom, the seed being sown thinly, as nothing is gained by putting in the seed close together. The total amount of soil covering the seed need not exceed 3 inches. The rows may be from 3 to 5 feet apart, according to the height to which the haulm grows. When the tops of the plants appear, nets should be stretched across the land to keep away sparrows and other birds. Slugs and mice must be guarded against, the latter from the moment the seed is put into the ground. The soil along the rows should be occasionally stirred, and dressings of soot and lime given to deter slugs from approaching the plants. Coal-ashes, with the fine dust taken out, and of the size that will pass through a quarter-inch mesh, is capital for defending the rows from the ravages of slugs, if it be laid down to a width of 6 inches on each side of a row.

Broad Beans may also be sown at the same time as the Peas, but being hardier plants, and less liable to suffer from birds or slugs, they require less care in the preparation of the land. Mice and rats, however, eat the seed, and these must be trapped. The best crops of Beans are grown on a heavy soil if it be drained, and if there is any difference in the kitchen garden as regards the quality of the soil, that which is heavy should be chosen to carry the Bean-crop. Early Longpod is still one of the best for sowing now, and the seed should be dibbled in 4 inches deep and 3 inches apart, the rows being 2½ feet asunder. In very heavy land the dibble-holes, or drills if that method be adopted, may be partially or wholly filled with light soil, as recommended in the case of Peas.

Cabbage.—The various plantations of Cabbage are making too rapid progress, and the earlier sowings are almost fit for cutting; and in the case of Cabbages intended for spring consumption, they are much too forward. The second sowing or main crop Cabbages are strong and promising, which all tends to show how prudent it is to make two or more sowings in late summer and early autumn. The Cabbage grub has given some trouble in our garden, attacking also

the late Lettuces. Whilst the weather remains open, all vacancies in the rows should be made good, and a little of the soil drawn up to the stems in order to steady and protect them.

Brussels Sprouts should be cleared of decaying leaves, which if left on the stems engender decay in the Sprouts; preserving, however, the green leaves and the heads of the plants, these providing some amount of protection to the Sprouts, besides, their retention keeps the latter from becoming loose and large. When taking the Sprouts, it is advisable to remove them with a knife at a short distance from the stem.

Rhubarb.—To force Rhubarb properly at this date, a decided check to growth is first needed, which follows from lifting the stools that are required, and leaving them exposed to night-frosts, and sun and wind, for one or two weeks, previous to placing them in heat. Of course, bottom-heat is not really necessary for forcing Rhubarb, although it helps the quick development of the stalks, and the best sort of heat is that derived from stable-manure one-third, and fresh tree-leaves two-thirds, thrown together in a heap for a week, and then turned, and well mixed together twice, when it will be fit for use. Having made the hot-bed in a pit, or frame, or dark cellar, and trodden all firmly together, wait a few days in order to ascertain if it is safe to place the roots upon it, which it will be if it do not rise above 80°. First place a layer of light soil, leaf-soil, or other, 4 inches thick, then proceed to pack the Rhubarb crowns close together on this, putting soil between and a few inches above them. A "dug-out" may be formed in the absence of other means, and the hot-bed made therein, covering it with hoops and mats, and above these with bracken or long litter.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leicestershire.

Pot Vines.—Vines not as yet started should be got in readiness forthwith, cleaning the house or pit in which they will be grown, white-washing the walls, and making the glass clear and bright, and seeing that the panes are sound, and there is no drip. A mass of fermenting leaves and manure should then be placed in the pit, and the Vines stood on pedestals of loose bricks, and plunged to the rims of the pots when the heat stands steady at 70°. The canes may be fastened to stakes temporarily close over the bed. Air in small quantities should be admitted night and day for a time; otherwise the moisture given off by the hot-bed will be too great, and in bright weather the canes may be sprinkled if they seem to be dry. A night temperature of 50° to 55° at the start, rising to 65° by day, will suffice. Close the vinery early after damping down.

Early Permanent Vinery.—The Vines from which ripe Grapes are required in May, should now be started after having thoroughly cleaned the Vines and the house. If mealy-bug be present on the Vines, remove the loose outer bark only, and wash the rods with soap-suds, then apply a thick coating of smooth clay two parts, coal-tar one part, and water sufficient to make it fluid; boil this in a saucepan till the ingredients are thoroughly incorporated; allow it to cool somewhat, and then apply it to every part of the old wood, especially about the cracks and holes around the spurs. When the Vines break, if a sharp examination be made daily of the rods, mealy-bug may be entirely eradicated in two seasons. To ensure this, however, hot-water pipes must be scrubbed clean; also woodwork, walls, glass, &c., and the crust of the border cleared out and replaced with new loam, &c. If mealy-bug be absent, it will suffice to wash the Vines with Gishurst-soap, at the full strength, recommended by the makers, adding to it a small quantity of flowers-of-sulphur. [We would advise caution with the use of Gishurst at the full strength, as injury to the buds has followed its use at this strength. Ed.] Apply warm with a brush. When the rods are dried, secure them to the rafters if they have often been forced early, but if they are young, secure them temporarily along the front of the vinery in a horizontal position to insure a regular break. The border should then be dug over lightly with a fork, and afterwards raked smooth, loosening it afterwards whenever it gets caked, taking care not to break any of the roots that may be running near the surface. Afford it a sprinkling of crushed bones and Thomson's or other vine manure, and over all a layer of turfy loam, to which soot, and lime-rubble in a small state are added, beating it with the back of a digging fork, and mulching lightly with stable-litter. The border, if dry, should have a heavy application of water at a temperature of 85°. Afford the Vines a night temperature of 50°, rising to 60° by day, and if

a heap of stable-dung and leaves be placed on a platform erected on the border, fire-heat may be spared at the beginning; and, moreover, the hot-bed will be useful for the forcing of Dutch-bulbs, Azaleas, Deutzias, &c. I would never have a plant in a vinery, but there are few places where the gardener is fortunate enough to be able to do this. As the foliage on succession Vines falls, pruning can be pushed on with, taking care to dress Muscats with styptic or knotting as soon as they are pruned; and on very aged Vines to lay in young canes wherever it is practicable. The repairs of all fruit-houses may now be undertaken.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Birtford, Dorking.

Mormodes, Catasetums, and Cynoches.—Many of these plants are showing flower-spikes, and although the new pseudo-bulbs at this time appear to have ceased to grow, the plants must not be removed to resting quarters before the leaves fall. Gardeners know that great numbers of these plants have been imported which, after blooming once or a few times, have, in many cases, dwindled away. The chief cause of this is traceable to the incomplete ripening of the pseudo-bulbs. In order to preserve such species, get them well ripened, and keep them in good condition year after year, the gardener should proceed as follows. As the plants go out of bloom, or have expanded the terminal leaf at the extremity of the pseudo-bulb without flowering, they should be removed from the East Indian to the Mexican-house, and afforded all the sunlight possible. Here they must be afforded plenty of water; and while the weather is bright, they will take water at the root almost every day, providing the potting-material dries quickly, and in dull weather they should be kept on the dry side. As the leaves commence to turn yellow, water must be gradually diminished, and if the pseudo-bulbs are well matured, no more will be needed by them for several months. If through lack of sunshine the pseudo-bulbs do not ripen, water will be needed occasionally during the resting season. After the leaves fall, the plants should be placed in a dry house, where the winter temperature is about 55°. If room can be found, the following species are well worth including in a general collection of Orchids:—*Catasetum tubulare*, *C. longifolium*, *C. barbatum*, *C. b. spinosum*, *C. scarrum*, *C. macrocarpum*, *C. saccatum*, *C. tridentatum*, *C. Christyanum*, *C. Bungeorothi* and its several beautifully distinct forms, as *Liudeni imperiale*, *aureum*, *punctatissimum* and *mirabile*; *Cynoches Egertonianum*, *C. versicolor*, *C. peruvianum*, *C. pentadactylon*, *C. chlorochilon*, *C. maculatum*, *Mormodes luxatum eburneum*, *M. buccinator* and its several distinct varieties, also *M. pardinum*, *M. p. unicolor*, and *M. Rolfei*. Strong plants of these species, after producing their first flower-spikes, will sometimes send out others, but it is advisable to pinch them off, otherwise the new pseudo-bulb may shrivel and fail to mature.

Dendrobiums.—All of the deciduous and semi-deciduous species of *Dendrobiums* now resting should be placed in a moderately dry cool-house, exposed to full sunshine, and well ventilated on warm days. It is advisable to look over the plants once or twice a week, affording water only to those which exhibit the least shrivelling. Such varieties as *D. Bensoniae*, *D. Parishii*, *D. crepidatum*, *D. cretaceum*, *D. primuminum*, *D. superbum*, *D. Pierardi*, *D. Dalhousianum*, *D. fimbriatum*, *D. calceolus*, *D. clavatum*, *D. albo-sanguineum* should not be removed to the cool resting house when growth is completed, but be placed at the coolest end of the East Indian or warmer part of the Cattleya-house during their period of rest. *D. Parishii*, *D. Bensoniae*, and *D. albo-sanguineum* should be kept quite dry whilst at rest, but the other varieties mentioned above must have water whenever the slightest shrivelling of the pseudo-bulbs is remarked. All *Dendrobiums* that are in full growth should be encouraged to make strong flowering stems. *D. Brymerianum* should be kept in the Cattleya-house at all seasons, as when grown in strong heat the plant deteriorates. The closely-allied species, *D. Harveyanum*, thrives best in the cooler part of the stove. Plants of *D. thyrsiflorum*, *D. densiflorum*, *B. Schroderi*, *D. Griffithianum*, *D. suavisimum*, *D. chrysotoxum*, and *D. Farmeri*, which are practically evergreen, have finished their growth, and should be removed to a light position in the intermediate house, but not dried off like the deciduous species, but afforded water occasionally so as to keep the foliage green and the pseudo-bulb plump. *D. sulcatum*, *D. macrophyllum*, *Richardi*, and *D. m. Veitchianum*, should be kept in an intermediate-house all the year.

PLANTS UNDER GLASS.

By G. H. MAVOROCK, Gardener, Luton Hoo Park, Luton.

The Propagation of the Tree-Carnation.—The autumn propagation of these varieties of Carnations results in plants of good size being obtained within a year from the time the cuttings are taken, and consequently an abundance of flowers. Many gardeners, myself included, strike Tree-Carnations from cuttings taken in the spring, and obtain plants of a useful size in this way, which usually have got into 5-inch pots by the end of the summer. These small plants are excellent for filling vases, and in other kinds of room decoration; but larger plants, and those which will give a lot of flowers for cutting, are raised from autumn-struck cuttings. These plants receive their final shift into 7 and even 8-inch pots. The cuttings should consist of growths that are of a moderate degree of firmness, with a heel; or if at this date the shoots or growths are wiry and hard, cut them at a joint, and place them round the edges of a number of 60's or small 48's, in a mixture of half leaf-mould and half sand, affording a thorough application of tepid water, and afterwards applying water with great caution. After the water has drained away, plunge the potful of cuttings in a frame having a bottom-heat of 65°, potting the cuttings singly as soon as they have as many roots as will support them. The cuttings should be turned out of the pots about six weeks from the time of placing them in the

at the roots, which will have the effect of resting them, and enabling a good start to be made in January. A temperature of 45° by night, and 50° by day, is high enough for the *Cliveia* in the winter.

***Schisanthus sinuatus* and *S. retusus*.**—These plants should be placed on a shelf, near to the glass in the greenhouse, and the stems secured loosely to neat stakes. Afford the plants no manure; but means should be taken to let them have plenty of ventilation, or damping will occur.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maidenhead.

***Gladiolus gandavensis*, *Nanceianus*, *Lemoinei*, &c.**—The leaves of these plants having matured, the corms may be lifted and laid out in a shed for a few weeks, until the tops part readily from the corms, when the latter should be stored out of the reach of frost in bags or drawers until the spring, or they may be hung up by the stems without removing the adherent soil. Some varieties, as the *Colvillei*, *Byzantinus*, and the old *Brenchleyensis*, may be left in the ground if this be convenient, as they withstand the frosts of an ordinary winter unharmed, if they are planted not less than 4 inches deep; in the event of frosts of more than ordinary severity, some litter or coal-ashes spread over the ground beneath which they are lying, afford sufficient protection.

FIG. 97.—THE MANGOSTEEN: SECTION OF FRUIT. (SEE P. 324.)

frame, when most of them will be found with plenty of roots for potting, and those which are not rooted should be dibbled into fresh pots, filled with the same sort of soil, made warm to receive them. The chief danger to guard against in striking Carnations in hot-bed frames at the winter season is damp; but losses from this cause may be averted by maintaining sufficient top-heat (65°) by means of linings or hot-water pipes, and affording a trifling amount of air day and night; it will soon be seen how much the cuttings will bear without flagging. If the sun should shine, a good deal may be afforded for a quarter of an hour. A damped cutting should be removed as soon as noticed, or it will very soon cause decay in others.

***Cannas*.**—All of those which were potted last spring, and have ceased to throw up flowering-spikes, should be afforded less water, for, although *Cannas* will continue to bloom if liberally treated for some time still to come, it is advisable not to prolong the flowering season too much. After the foliage has fallen, sufficient water is needed to keep the rhizomes plump. The plants should be afforded the protection of a greenhouse or a greenhouse-pit during the winter.

Seedling *Cyclamens*.—As soon as the plants have made one true leaf, and can be handled, they should be pricked off into shallow pans, and placed in a pit or house having a warmth of 55°, and near the roof-glass. On warm days spray the plants with tepid-water.

***Imantophyllum (Cliveia) miniatum*.**—The foliage should be cleaned by the use of sponge and warm water, and the pots and soil kept free from con-ferna. At this season much less water will be needed

Tuberous Begonias should be lifted with some of the soil attached, and laid close together in boxes, storing these under a greenhouse-stage or other cool situation, but protecting them from drip.

***Half-hardy Plants*.**—The specimens of *Fuchsia*, *Cassia corymbosa*, *Hedychium*, *Abutilon*, *Aloysia citriodora*, and other plants used in sub-tropical gardening, should now be taken up and potted, and afterwards placed under glass. *Hedychiums* that are still throwing up spikes of bloom may be placed in a warm greenhouse, to unfold their agreeably fragrant flowers.

Propagation of Own-root *Roses*.—A simple means of increasing *Roses* in this form may be practised at this season. Choose a border with preferably the west aspect, and a soil that is moderately light and well worked. If good strong cuttings of ripened shoots, 1 foot to 9 inches, and taken off with a heel, be inserted, a goodly percentage will form roots by the spring. It will suffice if two eyes or buds range above-ground, and all should remain and not be cut out as in making Gooseberry cuttings. The heel of old wood should be thinned down, not put in just as stripped from the plant. Having dug the soil and trodden it firm, and raked it level, proceed to open a trench at one end, cutting this with an almost perpendicular side; and in this strew a small quantity of sand or sandy soil, and proceed to lay in the cuttings against the soil at 6 inches apart, pressing the sand, &c., around the cuttings, and over this putting a little of the soil, and making this firm also. Then fill in the trench with the spade, tread gently along the row, level the surface, and pass on to the next row, and so on till the cuttings are inserted. The rows should not be closer together than 12 inches—a

distance that permits of some amount of growth being made next summer without undue crowding, and of a man trampling the soil firm when loosened by frosts. Many varieties of H.P. strike readily in this manner, as do most of the climbing *Roses*, as *Boursault Prairie*, *Ayrshire*, *Polyantha*, *Madame Despres*, *Crimson Rambler*, *Innocente*, *Felicité*, *Perpetué*, and many others.

Rose Planting.—The present month affords a good time, if it be open, for planting any kind of *Rose*, and preparation for this kind of work should be made forthwith. Where existing beds of *Roses* have become impoverished, let the plants be lifted and laid in by the heels elsewhere; then, having cleared the beds, afford them a heavy dressing of rich manure and new loam if it be handy, and trench the soil two to three spits deep. Having done this, let it settle for a week, then trample it evenly all over, and proceed to plant, re-arranging the *Roses*, always affording ample space for development, and not planting them deeper than they were before. Before planting, trim the roots somewhat; remove all brood visible on the roots of worked *Roses*, and be sure that the roots are not crammed into holes too small to hold them. Make the ground firm about the roots, drawing a little of it conewise round the stem. New *Rose*-beds must be treated similarly, but loam in good quantity should be used if the soil be light, and the more clayey the loam is the better, removing some of the staple to make space for it. If the drainage be good, it rarely happens that a heavy soil requires making lighter; but if it be very tenacious, burnt earth, leaf-soil, and road-sand are capital substances wherewith to lighten it. Although planting may be carried out at any time in the winter when there is no frost in the ground and the weather is mild, the present month and March are the best seasons. All *Rose*-beds that have been replanted, and new beds, should be mulched before the frost has had time to enter the soil. A selection of varieties will be given in my next Calendar.

THE APIARY.

By EXPERT.

Food for Bees.—The following is a recipe for soft candy: (1). Use preferably a brass jelly or preserve-pan, otherwise an enamelled-iron or plain-iron one. (2). Put in 10 lb. of white granulated sugar at 2d. or 2½d. per lb., 2 imperial pints of cold water, and half a teaspoonful of cream-of-tartar; (3). Set on, or hang over a brisk fire, and stir up gently now and then till the sugar is all melted; this should require about fifteen minutes. (4). Almost immediately afterwards the whole will reach the boiling point, at first throwing up a deal of froth. The fire may be moderated or the pan withdrawn a little at this stage, when the foamy boil will settle down to a clear crackling one; this boiling should only occupy about two minutes. (5). Now let a drop fall on a cold surface, withdrawing the pan from the fire in the meantime. If the drop at once begins to set, so that in a few minutes it will draw out as a thread when touched with the finger, the mass is cooked enough. If not, boil a few seconds longer, and try again. (6). Remove the pan from the fire, and set it in a trough of cold water. It may be left there for a few minutes, while the moulds (flat or soup plates will do) are being set ready, each with a thin sheet of paper rather larger than the mould laid in. Returning to the pan, commence and continue to stir briskly, until the mass begins, first to get dim in colour from incipient granulation, and then to thicken to the consistency of thin porridge. Then pour into the moulds, warming the remainder slightly to get it to leave the pans. This cooling and stirring process should take about fifteen minutes more. (7). Thus, in about thirty-two minutes, we finish the whole process, with the result that we have 12 lb. of candy from 10 lb. of sugar. The cakes should set within an hour, so as to be safely turned out of the moulds. When quite cold they should still be soft enough to be easily scratched with the fingernail, and to melt in the mouth with a soft grain. (8). Bees never hibernate in the full sense of the term. They will be found even in the most severe frost, ready to move as soon as sunlight is shed on them. All stocks need preparing for the winter without delay, because bees that are packed in early autumn, generally speaking, commence breeding earlier and come out stronger in the spring than those that are disturbed late in the year, by feeding and packing. See that all hives have a good number of bees in them, and a young queen at the head of the colony, together with an abundance of food. These items secured and the bees housed in a hive that is waterproof, the bee-keeper will have but little to do or think of in relation to his apiary for the next four months.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, Nov. 9	Royal Hort. Soc. Coms. National Chrysanthemum Society's Show at Aquarium (three days). Chrysanthemum Shows at Leeds, Kingston, Birmingham, Croydon, Bromley, and Farnham.
WEDNESDAY, Nov. 10	Chrysanthemum Shows at Liverpool, Eastbourne, Carlisle, Hanley (Staffs.), Brixton, Great Yarmouth, and Bournemouth. Harrison & Son's Show of Vegetables and Farm Roots, at Leicester.
THURSDAY, Nov. 11	Chrysanthemum Shows at Putney, Hammersmith, Spalding, Tunbridge Wells, and Winchester.
FRIDAY, Nov. 12	Chrysanthemum Shows at Sheffield, Wilmalaw, Windsor, and Bradford.

SALES.

MONDAY, Nov. 8	Bulbs, at Protheroe & Morris' Rooms. Bulbs and Plants, at Stevens' Rooms.
WEDNESDAY, Nov. 10	Bulbs, at Protheroe & Morris' Rooms. Lilies, &c., at Protheroe & Morris' Rooms. Bulbs and Plants, at Stevens' Rooms.
THURSDAY, Nov. 11	Bulbs at Protheroe & Morris' Rooms. Bulbs and Plants, at Mr. Stevens' Rooms.
FRIDAY, Nov. 12	Bulbs and Orchids, at Protheroe & Morris' Rooms.

PROVINCES.—November 3 (6 P.M.): Max., 50°, South-west Ireland; Min., 45°, East Counties.

Autumn versus Spring Digging.

THE subject of digging will be in the minds of many horticulturists at the present time, and the younger members of the "fraternity" will do well to study the respective advantages of performing this operation in autumn and spring. It is a more important matter than appears at first sight, because modern investigation has thrown a fresh light upon much connected with the soil and the conservation of its properties. It is always unpleasant to be compelled to recognise mistakes, but when a practice is proved to be erroneous or wasteful, it is wise to alter our course, as a good deal of success in life depends upon the readiness with which new ideas can be assimilated in regard to our work or duties.

For a large number of cultivated plants, the supply of nitrogen is of the utmost importance, and this is obtained chiefly from the nitric acid of soluble nitrates derived either from applied manures or from decomposing substances already in the soil. During the summer months, and with a due amount of moisture

present, the production of these sources of nitrogen proceeds continuously and at a much greater proportionate rate of increase than in the winter. The constant stirring of the surface by means of hoes or other instruments in the warm months considerably accelerates the formation of the compounds named, by the admission of air that aids in the work of breaking up insoluble substances. Thus, if a piece of ground is unoccupied by a crop during the summer, and it is attended to in the surface-stirring mentioned, there is by the time autumn arrives a material increase in fertility. Even if it be occupied by a crop, unless it be a very exhausting one, or close planting is adopted, there may be some accumulation if the land has been previously well manured. At any rate, the actual loss by drainage will have been small, because the roots of the plants will have appropriated all within their reach.

In the autumn and winter, however, the condition of affairs is reversed; so long as the soil continues warm, and not over-saturated with water, the nitric acid formations will continue, though in a lessening degree, until in the winter very little indeed is produced. Then, too, we have the greatest waste going on, particularly in a wet season; the compounds formed during the summer are rapidly washed away if the soil is not occupied with a crop, and we have to make up this loss by the addition of costly manure, or the land becomes impoverished.

Regarded, therefore, solely from the point of view of naturally increasing the fertility of the soil, we know that in digging ground in spring or summer we are certain to gain, while the same operation in autumn or winter will as certainly lead to some loss of the constituents, and perhaps in a great degree if the winter prove to be wet. In both cases this is assuming the ground to be unoccupied—but in few gardens can ground be allowed to lie fallow for several months; therefore it only occurs when a crop is removed in the autumn too late to put anything else on it. Then if it has to wait for a crop until spring it would be economical to defer the digging until spring. Appearances must, however, be studied in a garden, and a well-dug piece of ground looks much better than a bare plot. Beyond this, an ordinary rich garden soil that has been in cultivation for many years contains such a superabundance of humus that the winter loss is not a very serious matter, as it is soon made up by decomposition.

The mechanical advantage of autumn digging when dealing with rough and heavy ground cannot be questioned, as whatever loss may be sustained by drainage is more than compensated by improved workable condition of the soil, while the more ready escape of water increases the warmth of the soil. Heavy ground that has not been under good cultivation, dug roughly in autumn, and exposed to winter frosts, will be in a better state for planting in the spring than three times the labour could effect at that time. The rough exposure of ground to the frosts also has a tendency in a severe winter to greatly reduce the insect-pests which find shelter in the soil. Therefore, as in everything connected with horticultural work, a considerable amount of judgment is necessary, and a balancing up of advantages and disadvantages.

The subject has, however, a wider bearing than garden culture, for it affects the larger areas of land devoted to fruit plantations, and in these the pecuniary aspect is a serious matter. If a permanent plantation be formed

with considerable spaces between the lines of trees not occupied with bush-fruits or Strawberries, the continual cultivation of such spaces without cropping must result without manurial addition in gradually impoverishing the soil into which the roots of the trees are advancing. That this loss is increased by autumn digging there is no doubt, and against it we have to set two advantages, namely, the amelioration of heavy soil by exposure to weathering, and the fact that there is not the same demand for labour in other ways in autumn and early winter as in spring. There is an alternative method, and that is to crop the ground throughout the winter, the roots of the plants grown will then appropriate the soluble nitrates accumulated during the summer, or at least materially diminish the loss of drainage. A growing crop will further aid in drying the soil, as the evaporation from vegetation, even during the winter months, is greater than might be imagined. If a crop can be so grown that is saleable, if it will only pay for the labour and manure required, it will be a gain to the cultivator because it is keeping the land in good heart, and no crop can be grown without adding something in the form of humus to the soil. In districts or seasons when the intermediate crops cannot be sold, the course adopted by large growers and advocated by great authorities in America is to dig or plough them into the land. It is even contended that it is more economical to allow the land to become covered with weeds and dig these in early in the year than to dig the land in autumn, and leave it bare for winter. This is carrying a principle too far, for many of the smaller weeds will, during a mild winter, continue bearing seeds, and are thus laying up a store of work and trouble that only those can properly estimate who have had to deal with weedy and neglected land.

The storage of humus in soil is an important matter beyond all doubt, but it only gradually restores to land what the crops have absorbed. Sir JOHN LAWES says:—"Humus (in which term I include all vegetable matter in a state of decay) is very insoluble in water; but sooner or later it assumes the form of nitric acid, which combines with lime or other alkaline substances in the soil, and then becomes very soluble in water. These compounds rise and fall with the water in the soil, coming to the surface in dry weather, and passing into the drain, in the absence of growing vegetation, in wet weather. When a crop is in the full vigour of growth, the soil-water may contain more or less nitrate. Being soluble in water, and entering into no combination with the soil, nitrate cannot accumulate. Each year fresh nitrates are formed from the decomposition of the humus, the fertility of the land depending largely upon the amount of nitric acid liberated every year. What we call condition is so much added to the stock of organic matter which in the course of a few years is decomposed, yielding nitric acid and mineral substances.

Such cropping as is here referred to is, however, only applicable to fruit plantations where the spaces around the tree-stems and over the roots is kept entirely free from vegetation. Growing vegetation of any kind close up to the stems of trees can only result in injury, because the vegetables appropriate what is available for the trees; it is not possible to dig the surface-crop in, and it must be left there to yield, in very slow degrees, what was already at the service of the trees.

Summarising the whole matter briefly, it will be seen that autumn digging should always, where possible, be followed immediately by a crop of some kind. Without that there is a certain, though variable, loss of nitrogen-yielding and other compounds during winter. In gardens and in improving heavy soils, this loss is counterbalanced by other advantages, but in larger areas of land, such as fruit plantations, it is more economical either to crop the land or to leave the digging until spring.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, November 9, in the Drill Hall, James Street, Westminster, 1 to 4 P.M. A lecture on "Roots" will be given at 3 o'clock, by Prof. F. W. Oliver, D.Sc.

THE ROYAL GARDENERS' ORPHAN FUND.—At the first meeting of the Committee of the Royal Gardeners' Orphan Fund since the recess, held on the 29th ult. at the Hotel Windsor, Mr. W. MARSHALL presiding, the receipt of a bequest was announced from J. W. THOMSON, late nurseryman, Hayward's Heath, £457 5s. 11d., which is to be known as the J. W. THOMSON bequest, to be forthwith invested, and the proceeds to be devoted to the purposes set forth in the will of the testator. Also the following donations, for which the special thanks of the Committee were accorded:—

Rev. A. Lowe, Rangemore, Burton-on-Trent, £ s. d.		
proceeds of collection at harvest festival	6	1 6
Sandringham Cottage Garden Society	5	5 0
Wimbledon Horticultural Society, sale of flowers	5	0 0
Uckfield Chrysanthemum Society	3	3 0
J. Selway, Bottesanger	3	0 0
Per J. Roberts, Local Secretary, Ramsgate	2	1 0
Forest Hill Horticultural Society	1	10 0
Hessle and District Horticultural Society	1	4 8
Bradford Paxton Society	1	2 6
C. Herrin, Maldenhead	1	0 0
G. Carpenter, Wyke	0	10 0
J. Dunkin, Warwick	0	10 0
M. Kneller, Basingstoke	0	8 0

It was decided to hold the annual meeting at Anderton's Hotel, Fleet Street, early in February, when the election of children to receive the benefits of this fund will take place. Some other details of business having been gone through, the meeting concluded with the usual vote of thanks to the Chairman. The necessary nomination forms may be received on application to the Secretary.

THE LINDLEY MEDAL.—This medal was instituted in commemoration of the invaluable services rendered to horticulture in general, and to the Royal Horticultural Society in particular by the late Dr. LINDLEY. It was to be given preferentially for excellence in cultivation. If we are right, there have only been two gardeners thought worthy of this distinction since the medal was first instituted, viz., the late Mr. T. BAINES and Mr. JAMES ANDERSON. Can it be possible that no cultivators of equal rank have come to the front during the last thirty years? or has the Society forgotten its functions?

THE LATE PROF. BABINGTON.—We have to announce the publication by Messrs. MACMILLAN & BOWES, of Cambridge, of the *Memorials, Journal, and Botanical Correspondence of Charles Cardale Babington*, formerly Professor of Botany in the University. We shall take an early opportunity of advertising to this important book.

HORTICULTURAL CLUB.—The usual monthly dinner and conversations will take place on Tuesday, November 9, at 6 P.M. The subject for discussion will be "Lilies and Lily-diseases," to be opened by Mr. G. MASSEY, President of the Mycological Society.

SIR RUTHERFORD ALCOCK.—The death of this distinguished servant of the Crown removes from us one who added a love of botany to his other qualifications as a doctor, a military man, a diplomatist, and a governor. Horticulture and botany are under great obligations to him for the discovery and introduction of plants from Japan and other countries. The researches of JOHN GOULD VITCH were much facilitated

by Sir RUTHERFORD at a time when travelling in Japan was not so easy as it is now. *Picea Alcockiana* and other plants will serve to perpetuate his memory.

A GARDENER'S BRAVE SON.—It may interest our readers to learn that the brave piper, PATRICK MILNE, of the Gordon Highlanders, who sat up on his haunches, and continued playing his pipes after being shot through both legs, and amid a perfect hail of bullets, is the son of Mr. WILLIAM MILNE, gardener, Waterside, Newburgh, Aberdeenshire. Mr. MILNE is now well advanced in years, but still bears evidence of having been a man of powerful frame and athletic build.

THE LINDLEY LIBRARY.—It is interesting and decidedly satisfactory to see what are the books that have been in most frequent demand at the LINDLEY Library during the last year or two. FOSTER-MELLIAN'S *Book of the Rose* heads the list, closely followed by Miss ANHEEST'S *History of Gardening*. Next come Mr. BARRON'S *Vines and Vine-Culture*, Canon ELLACOMBE'S *Plant Lore of Shakespeare*, Mr. McDONALD'S *Sweet-Scented Flowers and Leaves*, and various works on *Fruit Culture and Vegetable Physiology*. Books that cannot readily be replaced are not lent, but it seems desirable in the interest of students and young gardeners that duplicates of text books and books in common demand should be added to the library, and it is very desirable that the funds at the disposal of the Trustees should be augmented largely.

NORFOLK COUNTY COUNCIL.—We are informed by Mr. G. W. CLARKSON, of the Clarkson Nurseries, Wisbech, that he has been appointed lecturer on horticulture by the Norfolk County Council.

GARDENERS AND WORKMEN AT THE ROYAL BOTANIC.—We learn that the working hours of the gardeners and others employed in the Royal Botanic Gardens, Regent's Park, have, owing to the endeavours of Mr. J. B. SOWERBY, the secretary of the Society, been assimilated to those current in the parks under the control of the London County Council and the Royal parks.

THE PRESENT SEASON has been remarkable up to the present for its mild weather. Pelargoniums, Dahlias, and other plants are still in bloom in many localities, being uncut by severe frost. We have received evidence from numerous correspondents to this effect, and before us is a box of flowers received from W. H. MAXWELL, Esq., Munches, Dalbeattie, Kirkcudbrightshire. These were gathered on October 30, at Bergairn, in the same neighbourhood, and about 2 miles from the sea, on the north shore of the Solway Firth. The box includes fresh flowers of Dahlias, *Anemone japonica*, *Calecarias*, *Begonias*, *Myosotis*, *Papaver orientale*, *Tropaeolum peregrinum*, *Clematis*, *Veronica salicifolia*, and other species. The circumstance is certainly noteworthy. Messrs. DOBBIE & Co. had also Dahlias and French Marigolds in full beauty at Orpington on November 1.

CONTINUITY OF PROTOPLASM.—In days not long gone by, students used to be taught that the cells of which plants are composed were closed bags, and that if any transfer of fluid from one to another took place, it was from osmotic action, or from a sort of oozing through the wall of one cell, and permeation through another. Mr. WALTER GARDINER, of Clare College, Cambridge, however, demonstrated the fact that there is in many cases an actual passage of extremely fine threads of protoplasm of one cell into the cavity of another, as occurs in the so-called sieve-tubes. Thus, the whole plant forms one whole instead of being made up of independent cells. Mr. GARDINER'S observations were confirmed and extended by others, so that the notion of the continuity of the protoplasm is now generally accepted. The bearing of these observations on the phenomena of variation, "sporting," graft-hybridisation, &c., is obvious. Mr. GARDINER, in a recent number of the *Proceedings of the Royal Society*, published on October 29, 1897, extends his former ob-

the case of the pitted-cells, which are so common in the structure of plants, the membrane which closes the pits is invariably traversed by threads of protoplasm. Other threads traverse the cell-walls, where there are no pits. These threads, it may be presumed, fulfil two purposes—the transmission of stimuli or influences (as in the case of the nerves of animals), and the conduction of food.

MR. BULL'S NURSERY.—It will be seen from our advertising columns that Mr. BULL has sold for building purposes the land occupied by his branch establishment at Ashburnham Road, Chelsea. The consequence is that a very large and very interesting collection of Orchids and other plants will be offered for sale by auction. Mr. BULL proposes in future to devote his attention exclusively to his old establishment for the introduction of new plants, &c., in the King's Road, Chelsea.

"THE FERN BULLETIN."—No sooner does any plant or group of plants become popular, than one of two things happens, or generally both. The one is the publication of a special journal, the other is the formation of a special society. Specialism is one of the characteristics of the time. It has its objectionable features, no doubt; but it has become a necessity, and we must make the best of it. One way of doing this is by securing, as far as possible, a good general all-round knowledge before diverging into a specialty. *The Fern Bulletin*, edited by Mr. WILLARD N. CLUTE, and published at Binghamton, New York, would not be so good as it is, were it conducted along the narrow groove of specialism without looking over the boundaries to the great world beyond.

LYCORIS AUREA.—From Mr. E. H. WOODALL we have received a fine truss of this old Amaryllid. The individual flowers were about 3 inches long, the perianth segments rather broad and reflexed, and of a rich golden-yellow colour, with projecting stamens and style. It is said to be a native of China, and was introduced so long ago as 1777, though it is not often seen in gardens. *Lycoris*, as a genus, differs from *Hippeastrum*, by having only a small number of seeds in each compartment of the ovary.

PARIS EXHIBITION, 1900.—Already the committees for the Exhibition are constituted. Group VIII., as we learn from the *Moniteur d'Horticulture*, comprises Class 43, devoted to horticultural material and practices; Class 44, kitchen-garden; Class 45, fruit and fruit-trees; Class 46, trees, shrubs, flowers, and decorative-plants; Class 47, stove-plants; and Class 48, seeds. The interests of each of these classes are to be served by a committee containing many distinguished horticulturists well known and appreciated on this side of the Channel.

M. DE PANNEMAER.—The well-known botanical artist of Ghent was recently entertained by his colleagues and friends on the occasion of the twenty-fifth anniversary of his entry as teacher of drawing at the Ghent School of Horticulture. An album containing portraits of his colleagues and pupils was presented to him, whilst the Government recognised his services by conferring on the artist the Civic Medal of the First-class.

TEMPERATE-HOUSE, ROYAL GARDENS, KEW.—We are informed by Messrs. MACKENZIE & MONOUR, Ltd., that they have been entrusted by H. M.'s Board of Works with the completion of the Temperate-house in the Royal Botanical Gardens, Kew, by the erection of the North Wing. The house is to be constructed with iron girders, and teak-wood window-sashes and sash-bars. It is expected the work will be completed in twelve months.

PATENTS.—The Patent Laws of this country make no provision for an official search as regards novelty, and all patents are taken out at the risk of the inventors. It is, therefore, incumbent on any person desiring to obtain a valid patent for an invention either to cause a search to be made, or himself to make a search, as to the novelty of his invention

By omitting such a search, many a patentee has found, after paying his fees, that his treasured patent is worthless, because it has been anticipated. Of course, in this case the first applicant or patentee possesses all the patent rights, and the second one has absolutely no rights at all. A complete and exhaustive search through published specifications of patents is a task of considerable difficulty, even for the trained expert, with all the resources of the Patent Office Library, for at this moment the number of printed specifications of patents is well over a quarter of a million. A series of indexes and abridgments has been published by the Patent Office as a guide to the specifications themselves, and is freely distributed to the principal public libraries in this country. The abridgments give a general description of the nature of every invention patented, and the object of their publication is to enable the would-be patentee to carry out, at any rate in some cases, what may be termed a "fireside search." By the study of these abridgments he will generally be able to select certain inventions which have already been patented, and which resemble his own invention sufficiently to render it desirable for him to examine their specifications in detail. A printed copy of any specification can be obtained at an inclusive price of 8d., through any post-office, by a special post-card (Patents Form C¹). The abridgments are published in volumes, each volume dealing with one particular class of inventions, such as "Steam-engines," "Cooking and Kitchen-appliances," &c., for a period of some years. The volumes up to 1877 are not illustrated, and all the subjects have not yet been dealt with; but from 1877 onwards a systematic series, very fully illustrated, is now in course of publication at a uniform price of 1s. per volume (including inland postage). The volumes from the periods from 1877 to 1883, and from 1884 to 1888, have been completed; those for the periods from 1889 to 1892, and from 1893 to 1896, are in active preparation, and later volumes will follow in due course. For the purposes of the abridgments the whole field of invention has been divided into 146 "Abridgment Classes," and the list of these classes in itself shows what an enormous field this is, and how greatly its products vary. Every triumph of applied science, such as the locomotive, the telegraph, and the dynamo, is to be found here, and every one of our great national manufactures and industries finds its appointed place. Each volume contains abridged descriptions of the inventions falling under one of the 146 classes during the period of which it treats (illustrated by diagrams or drawings wherever possible), a detailed index to the inventions according to their subject-matter, and an index to the names of patentees or applicants. For the use of those who desire to make a careful study of patents, the Patent Office also publishes an "Abridgment class and index key" (price 1s., parcel postage 5d.), which show in detail how inventions are classified, abridged, and indexed throughout its publications.

PRESENTATION TO MR. D. BROUGH.—At the "Kirkhouse Inn," Strathblane, N.B., on the evening of the 2nd inst., Mr. BROUGH, who has for the past five years had charge of the gardens and grounds of Sir ARCHIBALD EDMONSTONE, Bart., at Duntreath Castle, and who is now about to resign the charge there, was made the recipient of a handsome dining-room clock by the committee of the Strathblane Horticultural Society, the garden staff at Duntreath, and a few friends and well-wishers. Mr. LOVE, in making the presentation, paid Mr. BROUGH a high tribute for the manner in which he threw himself into the work of the Strathblane Horticultural Society, his attention to duty, and his straightforwardness. During these five years the finances of the Society had about doubled themselves; that again was due in a measure to his energy. He had much pleasure in asking Mr. BROUGH to accept this small token of the respect and esteem with which he was held by a very wide circle of friends. Mr. BROUGH, in a few suitable words, thanked those present for their beautiful gift presented to him, and for their good wishes and kind sentiments.

HOME CORRESPONDENCE.

PHYSALIS FRANCHETTI.—Seeing in your issue a note respecting the non-ripening of *Physalis Franchetti*, and having grown a large number successfully, perhaps a description of my methods would be acceptable to your readers, for it is a plant that may be grown by everyone. First, snails are very fond of it, and care should be taken to prevent it being eaten by these creatures when just coming up; it requires a good deep, rich soil; and towards July it should have some of the shoots thinned out, also some leaves removed thus exposing the calyces to the sun. By carrying out these directions I feel sure that these will ripen well almost anywhere in Britain. I send a calyx to show the size to which they grow with me, and to the number of eight to ten on a stem. It is quite dwarf as *P. Alkekengi*.—*J. P., The Ericas, King's Norton.*

THE R.H.S. AWARDS OF MERIT.—Would it not be well for the Royal Horticultural Society to make a change in the system by which the Awards of Merit are frequently made? I am referring to a case where two or more growers exhibit the same variety of plant or flower, and each share the honour. Would it not be better that the award be made to the best specimen? I will illustrate a case. On October 28 I placed before the Floral Committee of the National Chrysanthemum Society blooms of the *Chrysanthemum Lady Ridgway*, to which a F.C.C. was awarded. Some one connected with another firm of growers gathering that these same blooms would be placed the next day before the Floral Committee of the Royal Horticultural Society, also sent blooms of the same variety, and although these said blooms would undoubtedly have been passed by the committee, they being only one-third of the size of those I exhibited, the firm share equal honours with myself, who really won the Award of Merit, *W. J. Godfrey, Exmouth*. [Surely one certificate is enough, the repetition of them is becoming ridiculous. Ed.]

BLACK CURRANTS.—The Black Currant will grow in almost any kind of soil, but that which is deeply worked and well enriched with rotten manure suits them best. If the bushes were planted carefully at about 4 to 5 feet apart, they should be kept within reasonable bounds by the free use of the knife. I like to go over the bushes soon after the fruits have been gathered, and (where unduly thick) give the branches a good thinning out. Only a short time since, I observed Black Currant bushes, that were pruned on the spur method, like Red and White Currants. The yearly addition of plenty of strong young shoots should be the aim of the cultivator of Black Currants. In the case of old bushes, I have seen the entire cutting down of the heads practised, and with very satisfactory results, numerous shoots springing up from the base, which fruited abundantly for some years afterwards. Still, the best practice is to plant fresh bushes to take the place of those that are worn out. Baldwin's Black is a very heavy cropping variety, and a favourite with many; Black Naples is also an excellent one. *H. Markham.*

GARDENERS' SUPPLANTERS.—Judging by what one hears from time to time, there must be many imitators of the biblical supplanter Jacob amongst the gardening fraternity. Personally, I can enjoy a fair contest on any principle or point of gardening practice without feeling the least ill-will against my opponent if I am worsted. No doubt some of the numerous readers of the *Gardeners' Chronicle* will understand my point. I allude to the covetousness of those who, by unfair means, try to supplant a fellow-gardener who may seem to them to be in difficulties. Most of us are well aware of the necessity for prompt and energetic action on the part of anyone seeking a situation. To say the least, however, it shows bad taste when an applicant for a situation neglects to find out the truth of the matter before applying, as it may happen that it is not vacant. I fear it will have but little effect on these persons to know that situations gained by such means often bring misery in their train. These thoughts have been uppermost in my mind for some time, and to-night's post brought me two letters from distant friends, both telling me of a case bearing on this subject, which has occurred quite recently. The gardener whose post was likely to become vacant, is practically a stranger to me. Some evil-minded person started a report that he was dangerously ill; and in a short space of time, his employer received numerous applications for the situation. One of my correspondents met this gardener last week looking round a well-known garden in the vicinity of

London. He was then some 200 miles from his home, which is in Wales, and he seemed well and strong for his age. It may be mentioned that he has held his present post for over thirty years, and I am assured that he enjoys the full confidence and sympathy of his employer. *Overhanded, October 30.*

PLUM COE'S GOLDEN DROP.—I consider no wall devoted to the culture of Plums complete without the above most useful variety. The young trees perhaps do not fruit so freely as some kinds do, but when once they begin to bear, we have a Plum of great excellence. It has a property apart from its pleasing golden colour and high quality, which is not to be found in many of our juicy fruits, namely, the length of time it will keep in good condition after it has been gathered, if taken from the trees ripe and rolled up in thin tissue-paper, and placed on shelves in a dry fruit-room. A good west aspect invariably suits this variety, and if planted in good soil and well taken care of, the trees grow with great freedom. In fact, like most Plums, they are very apt to make too gross wood when in a young state. Many young trees are very frequently to be met with comparatively ruined, through not being kept checked by root-lifting, &c., in their early stages of growth. It might be argued that almost any soil will suit the Plum, but for walls I have always found it the better plan by far to prepare good soil for the roots, and this rammed firm; and should the trees break away into rank growth, check them by root-pruning. I often think the knife is wrongly used; instead of hard cutting the branches and shoots yearly, it would be better to cut the roots, and the latter I would strongly urge to be done at once where the trees are growing too strong to be fruitful. *H. Markham, Margate.*

MUSCAT OF ALEXANDRIA GRAPES.—In the *Gardeners' Chronicle*, October 30, p. 313, your correspondent, "B. W.," remarked that my letter was a trifle misleading. I should be very pleased if the writer would publish his experience in the *Gardeners' Chronicle*. I doing the same, then readers would be able to decide the matter. Airing is not only required in the summer and autumn, but from the time they are started, which, as a rule, is about the latter end of February or beginning of March. The Grapes about which I wrote took the 1st prize at Birmingham and Rugby shows, and I think that judges do not give 1st prizes to the worst exhibits. I cannot agree with "B. W." in saying that a double thickness of fish-net is not required if the airing is properly seen to. The way this letter reads is out of the treatment altogether, for to advise the putting on of a lot of air the first thing in the day is certainly misleading. The writer believes that Muscat of Alexandria can stand the hottest rays without shading. I am sure that the foliage of this variety flags sooner from strong sunshine than any other variety. It is not in the middle of the day that the foliage gets scorched, but the first thing in the morning when the sun is bright. If they are once neglected at this time, the damage is already done. Early closing is another practice that I do not hold with, and also syringing the Vines, because if the berries are wetted and the sun strikes them, the fruit gets scalded. And with early closing there is always the liability to scald. Therefore if "B. W." will publish his experience, I will do likewise. *A. Smith, Harewood House Gardens, Hendon.*

THE QUEEN'S DIAMOND JUBILEE.—It has occurred to me that it would be an interesting incident in this memorable year, to plant a group of sixty sapling Oaks in a suitable position in Hyde Park. [These trees do not succeed in London. Ed.] A group of Oaks would be a living monument of the auspicious occasion, and the group to be called the "Diamond Oaks." This suggestion is respectfully offered for the consideration of the London County Council, or the Park authorities; and were it adopted, I venture to assert that such a clump of these trees would be admired. On many estates, great and small, in this country, single trees in variety have been planted this year to commemorate the national event, but to plant sixty in one group in one of the London parks would, I think, be unique in character and appearance. This year of special interest, 1897, to the English people and the Empire, is now drawing to a close; still, there is ample time to carry out my humble suggestion, should it meet with the approbation of the authorities that be. *J. Gardner, Elsham Hall Gardens, Lincoln.* [It might be done at Windsor. Ed.]

A LAWN-SWEEPING MACHINE.—When on a visit to Petworth the other day, I saw one of Messrs. Sutton & Pull's lawn-sweeping machines at work, and

was much struck with its simplicity and the efficient manner it performed its work. Although there was a good lot of leaves, and many Chestnuts, the machine deposited them all in the collecting-box. It was being easily worked by two men, and the quantity of ground that they had swept with it proved what a boon it is to gardeners who have extensive lawns to keep tidy, as six men could scarcely have done the same amount of work with brooms in the time. Not only is it labour-saving, but the lawn, I thought, looked fresher than when swept with the broom. *H. Hereford.*

THE USE OF FLORAL LEAVES.—One has often heard the question put, "What is the object in Nature of the green leaves which we sometimes see developed at the base of the flower-cluster, at the upper end of the flower-stalks, of certain plants?" I have never heard any cogent or satisfactory answer given to the question, so I experimented on an outgrowth of that kind which manifested itself on the flower-stalks of some plants of *Primula farinosa* in my borders this summer. I pegged these flower-stalks down, on the method of pegging-down Strawberry-runners, and to-day I have taken them up as well-rooted offsets. This seems to prove that outgrowths of this kind constitute really a supplementary mode of propagation provided by Nature. By the way, I may observe that *Primula farinosa* with me proves to be a charming border-flower, blooming over a prolonged period, and affording a charming display of exquisite floral gems. It loves a magnesian-limestone soil. *G. Paul, 10, St. Mary's Avenue, Harrogate.*

YORKSHIRE APPLES.—I have read with interest Mr. Bunyard's paper on fruit-culture during Her Majesty's Reign; also the notes upon the non-competitive collections of fruit and flowers staged at the Royal Horticultural Meeting, October 1 and 2, which has led me to send samples of Apples that I have found to do well here for the last three years. Most of the trees from which these were taken were root-pruned in the autumn of 1893, and some of them slightly raised above the level of the surrounding ground; and they have since received an annual mulch of partly-decayed manure, and occasional waterings in hot, dry weather, and have twice been sprayed with sulphate of copper and lime in calm and mild weather in winter; 1 lb. of sulphate of copper and 1 peck of lime to 30 gallons of water. The trees of Warner's King, Bramley's Seedling, Tower of Glamis, Fearn's Pippin, King of the Pippins, Ecklinville, and Lord Grosvenor (of the two last-named I have no samples left), have borne regular and good crops, the trees having been planted four years ago. Small's Admirable, Stirling Castle, Domino, and Nelson's Glory promise well, and have given a good return for the last two seasons. Peasgood's Nonsuch, Blenheim Orange, and Annie Elizabeth, have borne regular but thin crops. The variety No. 10 has done well this year, it was grafted on an old stock of Golden Noble, and Cox's Pomona has borne well this year for the first time, being planted four years. Of Dumelow's Seedling I have only one tree, which is very shy, but generally it gives us a few useful late fruits. All the above are worth giving a trial in Northern gardens; the best for cooking being Lord Grosvenor, Domino, Nelson's Glory, Tower of Glamis, and Bramley's Seedling, which would give a supply of Apples from August till the end of April. Bramley's Seedling keeps sound and free from spotting, which is a common blemish in southern fruit of this variety. The best dessert Apples are Beauty of Bath and Irish Peach coming into use early, and Fearn's Pippin and King of the Pippins to follow. I am sorry not to be able to grow Cox's Orange Pippin. We want one as good that will finish its fruits well; can any reader recommend one, our garden being in the East Riding, 2½ miles from the sea-coast? I find several varieties of Apple shrivel here, and are useless, although left on the trees till very late. The ones numbered 13 for instance, I have left until the middle of November, but it never finishes fit for use. *Thomas Down, Wassand Hall, Hull.* [Cox's Pomona is a very fine fruit, although necessarily not of so high a colour as it comes in the south. Warner's King was 5 inches in width, and 3½ inches in height, a very fine specimen—of a weight of 19 ozs. Tower of Glamis was 4 inches in height and 4½ in width, an unblemished fruit—of this variety our correspondent informs us that he has fruits weighing as much as 1 lb. each. Annie Elizabeth was a perfect example, 3½ inches in height, and 4½ inches in width, of a weight of 10½ ozs. The fruit of Bramley's Seedling was 3½ inches high and 4½ inches wide, and of a weight of 18½ ozs. Blenheim Orange was a fine, high-coloured fruit, approaching ripeness; as was likewise Peasgood's Nonsuch, a fruit measuring 3½ inches in height, weighing 12½ ozs. Nelson's Glory was a nice-looking fruit of full size; as was also Norfolk Beauty. King of the Pippins and Fearn's Pippin were of fair size, and nice-looking fruits. Our correspondent does not volunteer the information, but we take it that the trees from which the fruits were taken were espaliers or bushes. In any case, they show in a very striking manner what excellent Apples can be grown in Yorkshire with the proper degree of attention in regard to shelter and providing suitable stocks, to root-pruning, thinning, and surface-feeding. In the matter of development, these fruits leave nothing to be desired. *Ed.]*

NEW PLANTS FROM THE SWAZI SURVEY.—The conclusions arrived at in the article on p. 273 of the *Gardeners' Chronicle* may be correct in a general sense but are scarcely so in the present case. It is pardonable for an amateur to mistake a quaint-looking Iris for a terrestrial Orchid, or even a *Sandersonia* for an orange Lily of the Valley. As to the Orchids, it is not stated whether they are epiphytal or terrestrial, but most likely terrestrial ones are meant; and is it not possible that a large number of these are still unknown? Mr. Von Weilligh has a good knowledge of South African flowers, and besides, he has a discerning eye for their peculiarities; this I conclude from his excellent and exact drawings and specimens which are before me, and I may safely predict that most of his finds will prove them to be new to cultivation, or even to science. The *Gladiolus*, "Green Giant," has leaves not 3 inches but 3 feet long; the so-called Lilies are *Arum* Lilies or Aroids, among which is a beautiful *Pothos*! In any case, honour is due to Mr. Von Weilligh for having selected these remarkable plants which will soon reach Europe, and then will be seen for themselves. *Max Leichlin, Baden-Baden.*

THE FINE AUTUMN.—A walk round the flower-beds and borders at Rystock, Exmouth, on October 27, revealed a wealth of beauty such as is seldom seen at this season. On the terrace-walk there are some thirty large vases filled with *Pelargoniums* in variety. Each vase having a separate coloured variety; large plants saved from last year were put out in the spring, and all through the season have been full of flower, and they are still very showy with Ivy-leaf *Pelargoniums* and *Lobelias*, full of brightness and beauty. The flower garden, though much past its best, has still some beauty; the beds of tuberous *Begonias* are a mass of colour, the *Coleus Verschaffeltii* is past its best, but *Iresine Lindeni*, *Ageratum*, *Mesembryanthemum*, bronze and tricolor-leaved *Pelargoniums*, besides one named *Verona*, are bright, gay, and attractive. In other trees and borders we have *Dahlias* in quantity, the colours of the blooms being unusually clear and bright; *Sweet Peas*, *Fuchsias*, *Salvias*, *Michaelmas Daisies*, in variety and quantity; *Cosmos bipinnatus*, *Chelone barbata*, *Rudbeckias*, *Helianthus*, herbaceous *Philoxera*, fine rows of *Coreopsis*, *Scabiosa*, *Leptocoryne*, *Cannas*, still bright; *Marguerites*, *Stocks*, *Violets*, *Carnations*, *Schizostylis coccinea*, *Nicotiana affinis*, &c.; beside *Azalea amona*, just about opening; *Roses* in quantity, and *Gladiolus* still gay. Turning from these outside, the *Chrysanthemums* are now well advanced under glass, the blooms of fine size, freshness, and form. *W. Swan, Bystock.*

VANILLA PLANIFOLIA.—Seeing your note on the fertilisation of *Vanilla* blossoms, perhaps it may be of interest to know how this was managed successfully, during the time I had charge of these plants, when at Osberton in 1881-83 as first fruit journeyman, under the late Mr. S. A. Wood. The *Vanillas* were grown in pots in the succession Pine-stoves, which had three-quarter-span roofs, the pots being plunged in the tan over the rims, the stems trained up the iron columns that supported the roof, and covered with sphagnum-moss, which became in a short time a network of roots. The plants were syringed every morning and afternoon in the summer, and the house was kept moist except during the flowering and ripening period, when the air was kept on the dry side. Lead wire was used to secure the growths, and the sphagnum-moss; and the roots travelled over the whole bed. The glass in the roof was thick rolled plate, which prevented the scorching of the leaves, and we had no difficulty whatever in fruiting them. I have had as many as thirteen pods on one spike, and most of them 6 to 8 inches long, and perfectly straight. The "Squire," as the owner was called, never failed to have a peep at them when on his way through the garden. *E. Young, Grange Garden, 22, Chesham Road, Brixton.*

CHRYSANTHEMUM GOSSIP.

CHRYSANTEMUMS IN SURREY.—At this season of the year, when the great flower of autumn is in such superb bloom, and *Chrysanthemum* excitement runs high, it is but natural that those interested in the flower should wish to see the best collections. I have done so within the past few days in my own county of Surrey, and have been for the trouble taken rewarded by seeing remarkably fine specimens. It was on the occasion of paying the visits difficult to reconcile the really splendid June weather with the *Chrysanthemum* in full bloom, but so it was.

DOWNSIDE, LEATHERHEAD.

It is not remarkable that great interest attaches to the general condition of the collection at this place, for was not Mr. Tate's able gardener, Mr. Mease, practically the champion grower of last year? What position he may occupy this year has to be shown; but if he does not occupy the same high place, it will not be for lack of plants and blooms, or for want of trying. He would, indeed, be a wonderful grower who could command the highest position for many years in succession, especially in face of the strong competition and the able growers found on every side.

The Downside collection is chiefly housed in two large spans, and stands on centre beds, so that the blooms come near the glass. That the blooms like such a position is evident, as colour and form both attest. The more light they get, evidently the better they like it. Still, the formation of the houses, whilst giving ample light, yet to some extent breaks the force of strong sunshine, and that is better than is the employment of shading, which should only be resorted to when unavoidable. When blooms are finely developed all too early, it is wise to remove them to a cool place entirely rather than to employ shading for all the plants in the house. Mr. Mease has a high reputation for doing incurveds well, and that he will show these less easy-to-finish flowers in fine condition this season there can be no doubt. Whilst many of them were not so forward, relatively, as the huge Japanese, yet the grower knows so well how to time his blooms, that his judgment may be relied upon to have them at their best when wanted. Amongst fine flowers were *M. P. Martignac*, pale yellow, very deep; *Globe d'Or*, *Baron Hirsch*, *Brookleigh Gem*, *Austin Cannell*, reddish-maroon, very fine massive petal, fine form, a beat-out Refulgence; *R. A. Babuant*, *Madame Darier*, *Jeanne d'Arc*, *D. B. Crane*, fine golden hue; *Major Bonafon*, *Charles H. Curtis*, both grand yellows; *Noel Pragnell*, the striped variety; *R. C. Kingston*, *J. Lambert*, *Violet T. M. Lin*, *Princess of Wales*, *Robert Petfield*, *Robert Connell*, *Lucy Kendall*, and many others. These, and in every case fine blooms, serve to show something of the Woodside incurveds.

Japanese are legion. Whites and yellows are not only in rich profusion, but in new varieties they dominate largely. Here there are in grand form *Vivian Morel*, *C. A. Davis*, and the newer and beautiful sport, *Lady Hanham*; then *Edwin Molyneux*, still finest of all the crimson, is superb and numerous. How grand amongst yellows is *Phœbus*, and even the good old *Sunflower* is excellent. *Australian Gold* is very fine, and *Lady Byron* is a fine white. *Mutual Friend*, another good white, is there, so, too, are *Mrs. Weeks*, and the beautiful *Madame Carnot*. *M. Hoete* is a large flower, pale pink in colour, and has long ribbon-like petals; whilst *M. Marius Ricoud* is magenta-coloured, and a charming flower. *Modestum* is a grand incurved yellow Japanese. *Mrs. C. Blick* has very solid blooms. *A. H. Wood*, the yellow sport from *Primrose League*, gives superb flowers; so also does *Simplicity*, a remarkably fine white. Another noble white is *Mrs. J. Lewis*. Of fine incurved form is *Lady Isabel*, somewhat lavender-shaded; but perhaps the noblest of this type of flower is *N. C. S. Jubilee*, very massive petal, broad, and colour mauve shaded blue. This seems to be the bluest yet put to commerce. How fine here, as everywhere, is *M. Chenon de Leché*, the great flower of last year. *John Neville*, rich chestnut; *Ethel Addison*, *Robert*

Powell, Colonel W. B. Smith, Pride of Madford, Beauty of Exmouth, Baron Tait, Lady Ridgway, Pallanza, Edith Tabor, Miss Dorothy Foster, a very fine variety; *Australie*, and others, suffice to tell of the great variety grown here. *A. D.*

AT WOOD-HATCH.

The superb show of Chrysanthemums annually made for Mr. T. B. Haywood at this charming place by Mr. C. J. Salter, lacks nothing in beauty, or interest, or quality, this season. The plants are housed in two long and none too high lean-to's, where intermixed they make a beautiful show. The houses, as well as the position, are warm, and the blooms seem rather advanced; but it is better to be a little forward than too late. In every case the blooms seem to be of the finest form, and the plants are in perfect condition.

Amongst Japanese, very fine indeed, apparently almost unbeatable, were Lady Ridgway, everywhere good; Madame Gustave Henry, a beautiful white; Pride of Exmouth, Mrs. Harman Payne, Lady Byron, Mdle. L. Zede, lilac; H. Jacotot filz, very fine; Mrs. J. Lewis, the superb new white; Thos. Wilkins, in fine form; Col. W. B. Smith, Surprise, rich rosy-magenta; C. A. Davis, Lady Hanham, Vivand Morel, Pride of Madford, Mrs. C. Blick, Louise, Mutual Friend, Australian Gold, Miss Elsie Teichmann, broad petals, white, flushed lilac; Phœbus, in great form; A. H. Wood, much superior to G. J. Warren; Edith Taber, A. H. Fewkes, Lady Isabel, Mrs. C. Orchard, *Australie*, Thos. Wilkins, Col. Chase, a lovely flower; Madame Rosarie, Modestum, here with the Vivand Morels, on 3 feet plants, in 32's, carrying grand flowers; and many more. Then of incurveds, very fine indeed were C. H. Curtis, Princess of Wales, D. B. Crane, Major Bonafon, Empress of India, Globe d'Or, Mrs. Norman Davis, Violet Tomlin, Lord Alcester, J. Lambert, Queen of England, Madame Darier, Prince Alfred, and others too numerous to mention in detail. Beyond these, the collection is very strong in reflexed and Anemones—indeed, of these latter, there is a fine representation; and in another house are singularly perfect and beautiful Pompons in great variety. Many growers may have more large-flowered forms, but this collection is so rich in variety, and is essentially representative. The entire group is one which any gentleman may well be proud to possess, for it indicates on the part of the gardener very high capacity; still, whether in Orchids or Roses, or in anything else, all is admirably done.

BRAMLEY PARK, GUILDFORD.

Lower down the county is the fine collection which Mr. Henry Paddon has grown for Colonel Ricardo at this place. The Chrysanthemums here have not been noticed appreciably in the past, but judged by what was seen the other day, the merits are not a bit behind those of the very best. Generally, the blooms as found on the plants in the warmest lean-to's, were forward, but they were in grand form. Were Mr. Paddon to enter the lists with some of the big growers he could hold his own well. In the Guildford district he is rarely beaten, but being of very modest deportment, he does not fly at high game. In referring to his Japanese flowers, names already becoming familiar have to be repeated. Those very fine were: Mrs. Weeks, John Neville, Modestum, intense yellow; Pallanza, here remarkably good; Madame Carnot, Pride of Exmouth, M. Chenon de Leché, A. H. Wood, La Moucherette, Phœbus, Pride of Madford, Australian Gold, Dorothy Seward, Boule d'Or, Simplicity, here a grand white; *Australie*, Mrs. J. Lewis, General Roberts, Graphic, Vivand Morel, Lady Hanham, Oceana, a splendid yellow; Mutual Friend, Colonel W. B. Smith, H. L. Sunderbruch, Madame Gustave Henry, Lady Ridgway, Lady Byron, Miss Elsie Teichmann, Deuil de Jules Ferry, with others, serve to show that the collection is well up-to-date. Then of incurveds, these generally being very strong, were C. H. Curtis, Golden Enpress, D. B. Crane, Lord Alcester, Queen of England, Mrs. R. C. Kingston, Globe d'Or, Lady Kendall, Violet Tomlin, Miss Aggas, Robert Cannell, with many more. These three

collections alone place Surrey in a very high position as a Chrysanthemum county. *A. D.*

CHRYSANTHEMUMS AT ELMHURST, READING.

A large display of well-developed Japanese Chrysanthemums may be seen at Elmhurst, Reading, the residence of G. W. Palmer, Esq. As large and handsome flowers are preferred by his employers, Mr. B. Dockerill, the gardener, produces them of fine quality, and the plants, from their vigorous and healthy foliage and sturdy habit, show him to be an adept in cultivation. The variety, Amos Perry, a beautiful golden-yellow-hued incurving Japanese, was observed in superb character; it is rather tall in growth. W. H. Lincoln is also very fine, with a richness in the colouring not always seen. Pallanza and other yellows were furnished with fine blossoms. There were some remarkably good blooms of Colonel W. B. Smith, also somewhat tall in growth; and others of Charles Davis, Vivand Morel, Charles Shrimpton, Edwin Molyneux, Etoile de Lyon, John Shrimpton, Madame Ad. Chatin, M. Chenon de Leché, Phœbus, W. G. Hewitt, and others, are in the collection. Mr. Dockerill grows Souvenir d'une Petite Amie, a dwarf and vigorous pure white variety, somewhat largely; the plants carry five or six blossoms, forming a bold head, and invaluable for decorative purposes.

It was at Elmhurst that Mrs. G. W. Palmer, the distinct sport from Mrs. C. Harman Payne, arose, which just failed to obtain a Certificate of Merit at the last meeting of the National Chrysanthemum Society's Floral Committee. This sport furnishes a very interesting illustration of bud-variation, for I was informed by Mr. Dockerill that he took out all the buds of the shoot which produced Mrs. G. W. Palmer, but divided them and struck them separately, after dividing them into top buds and bottom buds. The top buds all produced Mrs. G. W. Palmer, the lower ones another distinct sport, and of a better and more symmetrical build than the parent; the flowers have a lilac surface, with a silvery-lilac reverse, pale and delicate, but distinctly of a deeper tint than those of Mrs. C. H. Payne. Mr. Dockerill has twenty plants of this sport, and they are all quite uniform in character.

Early varieties are also grown, and some for their freedom of bloom for cutting, such as Rycroft Glory and Source d'Or. Fair Maid of Guernsey is one of the chief varieties grown for late blooming. Elmhurst is a compact place with Vineries, Peach and plant-houses, propagating pits, cold frames, &c. Much cut-bloom is required, and small foliaged plants for a variety of decorative purposes. Cyclamens, Chinese Primroses, and other spring flowering-plants are coming on for blooming at that period of the year. Some fine tuberous-rooted Begonias are just going out of bloom. Bushes of *Euonymus* are grown in pots for use in the flower garden. The condition of everything reflects great credit on Mr. Dockerill. *R. D.*

FINSBURY PARK.

It is no meagre praise to the Finsbury collection to say that it is as good as usual. Each year Mr. Melville has had a display that could only be accurately described in the superlative degree, and there is always a neatness and finish about the plants that is exceptional. They are arranged this season in the old span-roofed house, in one sloping bank, with undulations, and serpentine face. There is but one path through the house, and this is a narrow one—far too narrow to be quite convenient; for although our visit was made upon an ordinary afternoon there was a block of visitors for some distance outside the entrance door. Apart from this very considerable drawback, the house is a most suitable one for the plants. Abundance of side ventilation, and a warm-water pipe running round the sides, the atmosphere appeared exceptionally pure and buoyant. In such circumstances the blooms last the longest time possible. The exhibition was opened on Oct. 9, and there are something like 2000 plants on show. Some of the varieties that appeared best done were the following:—Beauty of Teignmouth, about which there has been so much dispute as to its correct name;

Hairy Wonder, a variety popular in all the parks as being an easy doer, and one of the best representatives of the hirsute class; Miss Elsie Teichmann, a large white Japanese incurved with lemon tint; the early-flowering and distinct incurved Japanese Louise; Colonel Conway, a very fine white flower; Avalanche, and the beautifully soft yellow Phœbus. Western King appeared to be the greatest novelty; and we noticed good blooms of Cullingfordi, G. W. Childs, Duke of York, Dennis Smith Rylands, and Madame Isaac, a large smooth-petalled Japanese flower just passing. The iron pillars in the centre of the house were hidden by tall plants of the beautiful variety Murgot and its freely-produced pale rosy-lilac flowers. A few Chrysanthemums are intermixed with the Palms and other plants in the newer house, which is used as a winter garden. Both of these buildings are close to the Manor House entrance to the park.

VICTORIA PARK.

One characteristic of the collection at Victoria is repeated year after year. Certain varieties such as Gloire du Rocher and Val d'Andorre, are obtained in unusually good colour. As Mr. Moorman, the superintendent there, is a recognised "Mum" man, and a member of the Floral Committee of the National Chrysanthemum Society, it is not surprising that the plants are grown well, or that the display in this park is one of the best. Nothing novel in the way of presenting them to the public eye has been attempted, though in such a large and comparatively wide house there would seem to be opportunity to do so. No doubt all the collections in the parks suffer in arrangement from the consideration that has to be given to securing a free passage through the house for the public, and one that presents the least excuse for dawdling. In the present case there is a good wide path through the centre, and the Chrysanthemums are arranged in banks from either hand. We noticed fine blooms of the following varieties:—Bouquet de Dames, H. L. Sunderbruch, Mrs. E. S. Trafford (Japanese incurved, palest rose and lemon—very pretty); Amiral Avellan, Val d'Andorre, Beauty of Teignmouth, the new Ideality, a white-flowered incurved; Lady Byron, with richly golden Modestum, Emily Silsbury, with large pure white flowers; Mrs. A. Gardiner, a purple-flowered Anemone; and Mrs. Caterer, a white-flowered Anemone; Mrs. E. S. Trafford, the sport from W. Tricker, has done well; and there are fairly representative blooms of Edith Tabor, the huge *Australie*, International, A. H. Fewkes, Oceana, Mr. Bunn, C. H. Curtis, and others. The Victoria Park display has been on view since October 14, and will be in good condition for some time yet.

SOUTHWARK PARK.

The arrangement of the Chrysanthemums at Southwark has always differed from that in the rest of the parks, and has been less stereotyped. To obtain local change, however, this season, the collection does not afford this novelty in the same degree. The plants are displayed in an irregular T-shaped house, and the plants are grouped on either side of a central path, that passes up the stem of the T, and out at one of the elbows, the other being blocked by tall Chrysanthemums. This is another concession to the "move on" system. The display was opened to the public on October 7, and has since been visited by very large numbers of people. At most of the parks there is a tendency to obtain an exhibition at too early a date, beginning with the first week in October, and becoming very much less attractive at the beginning of November, when we think it should only be approaching its best. This is the case at Southwark, and the recent fogs have helped greatly to hurry the bloom past. There has been a good show, and a large number of varieties are grown, amongst which the hirsute section is well to the fore in more than a dozen sorts. A few of the best grown varieties when these notes were taken were Mrs. Chat. Blick, Lord Alcester, Hairy Wonder, M. C. Molin, the large yellow Margery Kinder, Mrs. J. Shrimpton, Mrs. G.

Gover (a very fine colour for this distinct variety), Sunflower, Duchess of Wellington, and Emily Silsbury. The Superintendent is Mr. R. Curle, who used to be at Waterlow Park, and formerly at Sefton Park, Liverpool.

BATTERSEA PARK.

The visitors to this south-western park, upon entering the Chrysanthemum-house, are not slow to appreciate the one characteristic that claims the attention of the connoisseur. The house is span-roofed, with the plants arranged in one group, with sloping face, and there is a path down one of the sides; the rest of the house has been decorated with Pompon and other varieties in quite a captivating fashion. Above one's head as you pass down the house, the roof is covered for a good part of its height with long-stemmed decorative and Pompon varieties, from which hang bunches of the prettiest blooms in much profusion. Even the ends of the house have been treated similarly, and therefore the effect upon entering is just that described in the frequent exclamations we heard, "What a picture!" It may be worth while reminding some of us who are prone to be carried away with enthusiasm for large blooms, that to most visitors at Battersea, this feature we have alluded to seems to be most admired. Mr. Coppin and his grower, Mr. Wheeler, are to be congratulated. The general collection is good, but has suffered much from the fog prevalent during the last week, and it is fortunate that there is a number of plants in reserve to take the places of some that will soon have passed. Mrs. G. Gover, M. Chenon de Lohé, Edith Tabor, Inar-nutious, Sunflower, Lady Byron, Queen of England, Madame Carnot, Graphic, and Hairy Wonder are a few varieties that appeared in best form.

WATERLOW PARK.

Since October 16 the show at this park has been open to the inspection of the public. The conservatory and greenhouses are filled with a very well-grown collection of plants, and the Highgate people have no cause to complain of the display their caterers have provided them with. Naturally the atmospheric conditions here and at Southwark or Battersea are very different, and it is easy to observe the effect of these upon many varieties in the collection. At no park have we seen this season better blooms of Viviani Morel and its sport, Chas Davis, than Mr. Pallett has at Waterlow, the size and colour of the blooms being both very good. Though this is one of the smaller-sized parks, the Chrysanthemums are kept well up to date, as is proved by the presence of such novelties as Western King, a large white; Modestum, M. Chenon de Lohé (one of Calvat's prettiest varieties), Kentish White, an incurved Japanese, and others. Western King had not quite developed its flowers when we saw them, but they promised well; and equally good were buds of Madame Carnot that were just upon opening. Three good blooms upon a plant well displayed the beauty of Phœbus; and there were not wanting fine examples of Hairy Wonder, W. Seward, and Lady Byron—a good white variety necessary to any collection. The most noticeable of incurved were Mr. Buun and White Beverley, but others will be better later. Waterlow is a charming little park.

CONTINENTAL NOVELTIES.

MR. ERNST BENARY includes among his novelties—

Cuphea miniata compacta (Benary).—This novelty, growing about 8 inches high, forms the first departure from the type of the valuable *Cuphea miniata*. Its flowers are produced in great numbers in various shades of carmine, scarlet, crimson, and purple, and form a pleasing contrast with the fresh green foliage. The bushy little plants are certainly a valuable addition to our dwarf-growing annuals, the more so as they bloom until late in the autumn. They will be found useful for bedding, and still more so as pot-plants, being the first annual *Cuphea* suitable for this purpose.

Leptosyne Stillmani (Asa Gray).—This beautiful Californian annual (fig. 99) comes from the Sierra Nevada, where it grows at a height of 5000 to 6000 feet. With graceful, thinly-cut foliage, and growing about 1 foot high, the habit of the plant is bushy and compact, and each of the numerous flower-stems is crowned with a golden-yellow blossom of over 1½ inch in diameter, which remains five to six weeks in full beauty. In addition to the rapid germination of the seeds, a prominent characteristic of this *Leptosyne* is that it blooms within four to five weeks after sowing, surpassing in this respect almost every other annual. It is best to sow in the open air in sandy ground in a sunny situation.

MR. FREDERICK ROEMER, Quedlinburg, Germany, ANNOUNCES—

Helianthus annuus, Goldleaf.—Single Sunflower, with golden-yellow variegated leaves.

Myosotis alpestris Triumph.—This novelty is another variety of the early-flowering class, and is

FIG. 99.—LEPTOSYNE STILLMANI (HORT. BENARY).

likely to prove the best variety for blooming in winter, and principally for cutting. It is a sport from *Myosotis alpestris robusta grandiflora* (the Hen and chickens Forget-me-Not); the plants are of a vigorous habit, grow about 12 to 15 inches high, and they bloom like their parent, having the same large bright azure-blue-coloured flowers borne on long stems, with the characteristic central double bloom.

RAMIE FIBRE.

As most readers know, the reducing to economic value of Ramie fibre has engaged the attention of the Indian Government from time to time during the past half-century. Premiums have been offered for the production of machinery capable of solving the problem of £ s. d., and much inventive talent and many thousands of pounds have been enlisted in the solution of the problem; and it is only now that we find a German firm actually placing on the market very fine samples of spun Ramie, and showing samples of fine lace work (all fibre), and quite a lot of other things, either mixtures of the fibre with cotton or wool, or fibre backed with either cotton or wool. The material is readily receptive of dyes, which in many cases appear to add to the silken sheen. The durability is probably the same as that of other vegetable fibres under like conditions, but of this we have no information. Glazed cotton and jute, not to mention other substances, have at present a

strong hold on the market for hangings, cords, trimmings, and other upholstering adjuncts; but doubtless Ramie will have a good turn when it can compete on the same terms. E. O. [The samples of lace and thread point to many uses the fibre of Ramie can be put. Ed.]

PLANT NOTES.

HYMENOCALLIS MORITZIANA VAR. MAJOR.

I IMPORTED about a dozen bulbs in February, 1895, from Venezuela, of which only this one survived, and has since furnished both offsets and seedlings. It differs from the type described in *Handbook to the Amaryllideae*, J. G. Baker; (1), in the leaves, which in the variety narrow abruptly to the stalks; (2), the valves of the spathe are not reflexed (at any rate, at first); (3), the tube is longer; (4), the segments lanceolate; and (5), the style shorter.

This plant would therefore take a position intermediate between *H. Moritziana* and *H. undulata* (Herbert, non Hort.), and, in general, is remarkable for the gigantic growth of its noble, deep green, shining eucharis-shaped leaves. It is also remarkable for the great size of its spathe, and for the development of wide bracts at the base of every one of its flowers.

Individually, these resemble the finer forms of *H. speciosa*, but the cup is smaller, and the flowers, instead of opening within a period of about three days, expand successively over a period of about a fortnight.

DESCRIPTION.

Bulb—3 to 4 inches in diameter, with short, distinct neck.

Leaves—a dozen mature leaves at flowering time, strictly distichous, glaucous, on long channelled stalks, winged at the base to clasp the stem, persistent eucharis-shaped, but not waved, with small acute tip. Very deep green in colour. Regular in shape, measuring 15 to 19 inches long in the blade, by 9 inches or more in maximum width, narrowed suddenly to the stalks, which are from 1 to nearly 2 inches wide by up to 1 foot in length.

Scape—central, stout, glaucous, nearly 2 feet high, and bearing an umbel of about twenty erect, sessile, flowers expanding successively.

Spathe—remarkably developed, the outer pair of valves being 6 inches long by 2 wide, and large subsidiary valves (or wide bracts) at the base of each flower (some 4 inches by 1 inch).

Flowers—erect, on erect tubes from 6 to 7 inches long. Very fragrant; span 8 to 9 inches.

Segments—lanceolate, recurved, more than 5 inches long by ¾ inch maximum width.

Staminal Cup—small, distinctly toothed, about an inch long, by ½-inch diameter.

Filaments—spreading, bright green in the free ends, which are more than 1½ inch long.

Anthers—¾-inch long; pollen orange coloured.

Style—horizontal, bright green, an inch shorter than the segments. Stigma capitate.

Seeds—produced single (or, as in *Elisena*, rarely two in a pod), ripening in one month, irregular, light green in colour, less than an inch long by more than half inch wide. A. Worsley, Isleworth.

[The photograph of the plant kindly sent in the spring of the present year was unfortunately unsuited for reproduction. Ed.]

VARIORUM.

WHORTLEBERRIES.—What the Cloud-berry is to the Norwegians, the Whortleberry is to the people of the West. The "Whorts" grow plentifully on the borders of Exmoor. Their half-acid, half-aromatic, flavour make the Plum-like fruit just the proper thing to eat with Devonshire-cream. Like many other wild fruits, they are the joy of childhood, and are not to be despised when that happy period has altogether fled. *Western Mercury*.

ROYAL HORTICULTURAL.

Scientific Committee.

OCTOBER 26.—Present: Dr. M. T. Masters, in the chair; Mr. McLachlan, Mr. Veitch, Mr. Douglas, Prof. A. H. Church, Mr. Shea, Rev. W. Wilks, and Rev. G. Henslow, Hon. Sec.

Galls on Oak Roots.—With reference to the specimens exhibited at the last meeting, Mr. McLachlan observed that the name of the insect was now *Biorhiza aptera*, and that only one sex (the female) was known as occurring in the root-galls. As soon as it was hatched, the insect climbed to the terminal shoots and laid its eggs in the buds. The result was the common spongy gall, known as the Oak-apple. In this, both male and female insects were produced, and were formerly thought to be a distinct genus, under the name of *Teras terminalis*. The females fall down to the foot of the Oak and lay their eggs in the roots under ground, and so reproduce the root-galls. This dimorphism is characteristic of other gall-insects on the Oak.

Sub-pelorian Cattleyas.—Mr. Veitch exhibited two sprays, carrying several flowers of *Cattleya labiata autumnalis*, having the two front sepals assuming the form of lips. He observed that the same plant had repeated the peculiarity both last year and this, but the lip-markings are now more pronounced. The specimens were received from Mr. F. R. Lloyd, of Coombe House, Croydon.

Carnation Leaves, Malformed.—Mr. Douglas exhibited leaves with peculiar horn-like excrescences on the margins. It was suggested that they might be caused by acari. They were forwarded to Dr. Michael for investigation. Dr. Masters observed that a *Yuca* in the Botanic Gardens, Dublin, produced very similar structures every year.

Malformed Cauliflower.—Mr. Henslow exhibited a stalk bearing a cluster of short Asparagus-like shoots, the leaves being reduced to a bract-like form, suggestive of the name of Broccoli—viz., *Brassica oleracea* var. *Botrytis asparagoides*. Dr. Masters observed that it bore a very unusual appearance, really intermediate between a Cauliflower and a wild Cabbage.

DEVON AND EXETER GARDENERS'.

OCTOBER 27.—"How a Knowledge of Botany is a Help to Gardening," was the title of a paper read at a meeting on the above date, by Mr. R. HODDER, gr. to Mrs. Trevor Barclay, Ponsonby, Torquay.

A knowledge of the physiology of plants, or the various phases of plant generation, growth, and development, was, said the essayist, a great help to a gardener. A knowledge of structural botany, in telling a gardener the reason for, and the legitimate use of the different organs of a plant, enabled him to guide its development, and treat it with greater benefit to the plant, and with much less labour to himself. A botanist has a great advantage in fertilising and hybridising over a gardener who is wholly ignorant of the science. Indeed, some knowledge of the science was essential to anyone who aspired to success as a hybridiser. Gardeners, he thought, ought all to learn botany. The paper was illustrated with living specimens of plants, roots, underground stems, leaves, flowers, &c. Referring to cross fertilisation, the lecturer showed that while certain crosses were bound to result in failure, and thus proved an impassable barrier known to the botanist, there was a wide field in other directions to the scientific hybridiser.

The chair was occupied by Mr. H. STONEMAN, late Teacher of Botany at the Exeter Museum. The Secretary (Mr. HOPKINS), exhibited a branch of *Cedrus Libani* from a tree growing in a clergyman's garden, the tree having been raised from a seed of a cone picked from one of the remaining specimens of the ancient Forest of Lebanon. A. H.

TORQUAY DISTRICT GARDENERS'.

OCTOBER 27.—This society held a most successful exhibition on the above date. The chief feature consisted of a large number of table decorations, which occupied the whole of one end of the hall. Mr. F. Peacock, gr. to P. W. BUSHBY, Esq., was awarded 1st prize for a very light and graceful arrangement; Mr. Davis, gr. to Lady MACGREGOR, being 2nd. A very striking exhibit was that of Mrs. WILSON, composed of *Gloriosa superba* blooms and grasses. The groups of Chrysanthemums were grand, Mr. C. R. Prowse, gr. to Dr. W. FORD EDGELOW, being 1st with a splendidly arranged bank of blooms (this group obtained a National Chrysanthemum Society's Silver Medal).

In the cut-bloom classes, Mr. J. BILL, gr. to the Rev. H. HUTCHINS, won the premier honours. There was a small but attractive display of fruit. Mr. W. J. GODFREY, of Exmouth, staged some grand cut blooms of Chrysanthemums, including many new varieties; and Mr. WELLS, of Earlswood, and Mr. GEE, of Teignmouth, also exhibited. Mr. W. B. SMALE was represented by a fine bank of blooms, prominent among which was Mrs. H. WELLS, generally remarked upon as being the best bloom in the show. Messrs. CURTIS, SANFORD, & Co. (Ltd.), HORN & SONS, W. BURNING & SONS, W. ALLWARD, & Co., W. TUPLIN & SONS, and R. VEITCH & SON other trade exhibitors. The attendance was very large, receipts largely exceeding those of any previous

EXMOUTH MUTUAL IMPROVEMENT.

OCTOBER 28, 29.—The twelfth annual exhibition of Chrysanthemums, fruits, and vegetables, was held in the Market Hall on the above dates and was in every way most successful.

For thirty-six cut blooms of Japanese Chrysanthemums, Mr. FOSTER, gr. to H. HAMMOND SPENCER, Esq., Teignmouth, was 1st, after keen competition. The uniform size, depth, and freshness of the flowers in this stand were noticeable. Among his best blooms were Edith Tabor, Graphic, M. Chenon de Leché, Australia, Phœbus, Ch. Davies, Colonel Chase, and Australian Gold; Mr. J. LLOYD, gr. to E. STUCKY, was 2nd, only just a few points behind.

Mr. FOSTER was 1st for twelve Japanese blooms, showing finely; and for twelve incurved, with good flowers of J. Agate, Brookleigh Gem, Jeanne d'Arc, and Barbara, among his best blooms.

The groups of plants were scarcely so good as formerly, but the circular one from General ROCKE was well deserving the 1st prize awarded it; Mr. KINGSCOTE, gr. to Mrs. CRESSWELL, was 2nd.

Other 1st prizes to groups were secured by Mr. HART, gr. to Mrs. H. STEWART; and Mr. CHURCHILL, gr. to Mrs. HUME LONG.

The grapes were more numerous than on previous occasions, and some fine exhibits were made.

A number of special prizes were offered, among them being a class for table decoration, to be judged by ladies. For the best arranged basket of Chrysanthemum blooms with Ferns, Miss SCHNEBER was successful. A Diamond Jubilee prize, offered by the Society for the best twelve blooms arranged in vase, was won by Mr. B. PIKE. A fine group of plants and cut blooms were staged by Mr. W. J. GODFREY, who had many choice varieties and novelties in excellent form. S.

A FUNGUS FORAY AT CASSIOBURY.

OCTOBER 30.—By the permission of the Earl of Essex and Sir Matthew White Ridley, the annual fungus foray of the Hertfordshire Natural History Society took place on Saturday, in the Swiss Cottage Woods, Cassiobury Park, and the wood-walks adjoining Cassiobury House. The foray was under the direction of Mr. Hopkinson, and the fungi were identified by Mr. George Massee, of Kew.

In the morning, a party of eight crossed the park to the grounds of the Swiss Cottage, finding about twenty species in the park, and increasing the number to nearly a hundred, besides several species not identified at the time, in the damp woods on the opposite side of the River Gade to the Swiss Cottage, which proved to be a prolific hunting-ground, especially for microscopic forms. In the afternoon, the party, increased to upwards of twenty, entered the Cassiobury Wood-walks, and strolled along the old high road which passes through them. The number of species found in the morning was nearly equalled in the afternoon, thus almost doubling the record, and there was again a much larger proportion of microscopic fungi than has been found at previous forays. The great find of the day was that of *Agaricus* (*Clitocybe*) *Sadleri*, discovered by Miss Buchanan. The species was first found growing on a tub in the Botan'c Gardens in Glasgow, and there is no previous record of its occurrence in England. It has now been added to English species by a young lady whose native place is the same as that whence came the fungus, or at least our knowledge of its existence as a species. After a brief visit to the gardens of Cassiobury House, the wood-walks were left, and the members were kindly entertained to tea by the Society's Librarian, Mr. Daniel Hill, at his residence, "Herga." Altogether, an interesting and enjoyable day was spent, and with the satisfactory result of beating any previous record in the number of species of fungi found.

ROYAL HORTICULTURAL OF ABERDEEN.

OCTOBER 30.—The annual meeting of the members of this Society was held on the above date. Mr. James Murray, of Glenburnie Park, presided.

The report by the directors stated that one exhibition was held during the year, in the grounds of Gordon's College, Aberdeen. From a horticultural point of view the show was fully up to the average; but, although the expenses were reduced by the sum of £110, the financial results were very unsatisfactory, owing to the unfavourable weather. The Directors, however, had pleasure in reporting that there is a free balance of over £190 to carry forward to next year's accounts.

NATIONAL CHRYSANTHEMUM.

NOVEMBER 1.—A number of very fine blooms came before the Floral Committee at the meeting held at the Royal Aquarium on Monday last, and though the members of the committee were fewer than is usual owing to the occurrence of numerous exhibitions, the awards were made with great circumspection.

From Mr. N. MOLYNEUX, gr., Rookesbury Park, Fareham, came Japanese, Mary Molyneux, a flower having a pale purple ground colour, with silvery reverse—a fine incurved variety that received a First-class Certificate. And his new white incurved, Mrs. N. Molyneux, a grand flower in the

style of Empress of India, but considered to be sufficiently distinct to merit a First-class Certificate of Merit. Japanese Princess Charles of Denmark, the committee wished to see again, it being a very promising flower; its colour, buff with a centre of orange-yellow hue.

From Mr. B. Dockerill, gr. to G. W. PALMER, Esq., Elm-hurst, Reading, came Mrs. G. W. Palmer, the rich bronzy and buff-coloured sport from Mrs. C. H. Payne, in much better form than it has hitherto been seen. It was unanimously awarded a First-class Certificate of Merit. From the same place came Miss Kittie Barratt, which came on the same shoot as Mrs. G. W. Palmer, six blooms being shown; but the committee regarded this as the true original form of Mrs. C. H. Payne, this variety of late having developed a rough and pale character.

Mr. H. WEEKS, gr., Thrimpton Hall, Derby, sent some seedlings of his own raising, and one of these, W. Cursham, a very promising variety, dull red, with amber reverse, the committee wished to see again. This was said to have been a seedling from G. C. Schwabe crossed with R. Owen. Two others have pretensions to character, and will no doubt be seen in better condition another season.

Mr. WILLIAM WELLS, Earlswood, Redhill, sent several Japanese and incurved varieties, among them G. J. Warren (First-class Certificate), a pale yellow-sport from Madame Carnot, which showed a greater depth of colour than has been before observed. N. C. S. Jubilee, a flower of a very pleasing delicate tint of mauve-lilac shade, with an ivory reverse, is very promising and was Commended. Directeur Liebert, amaranth, with soft shade of silvery-pink on the reverse of the florets, was in better character than we have previously seen it. Some new incurved were also shown by Mr. WELLS, the most promising being Topaz Orientale, a large pale-yellow bloom, loose in the centre as shown; and Lady Isabel, a flower of delicate purple shade, silvery-white on the reverse of the florets. From Mr. W. J. GODFREY, nurseryman, Exmouth, came a batch of new varieties, and First-class Certificates were awarded to the following Japanese varieties:—Mrs. F. A. Bevan, very soft pink with a silvery reverse—a full and beautiful incurved Japanese; George Foster, a grand incurved Japanese of excellent shape, with broad florets of a soft yet bright yellow colour; and Mrs. Charles Birch, incurved, white, the broad base florets of a soft shade of bright lilac colour; Admiral Ho, pale yellow; President Norm, rich bright buff, distinct, and pleasing in colour—the blooms being rather small, the committee wished to see it again; and Mrs. Hunter Little, soft yellow hue.

Mr. J. OLLERHEAD, Wimbledon House, Wimbledon, sent Japanese Lemawee, one of Messrs. Nathan Smith & Son's raising, Adrian, U.S.A., the colour bluish-white, the long basal florets of a delicate pink hue—a very pleasing sort of flower, of good quality. It was awarded a First-class Certificate.

M. ALFRED CHANTHIER, Bayonne, France, sends some seedling incurved flowers, but they were not sufficiently matured to enable the committee to judge accurately of their merits.

From Mr. R. OWEN, nurseryman, Maidenhead, came several new varieties, chiefly of incurved varieties, one of which, Thomas Lockie, white, with slight lilac base to the florets, the committee wished to see again. Thomas Singleton, white with deep pink base, fine in shape, was also of a decidedly promising character. Japanese Royal Standard was very fine in colour, but somewhat loose in texture, and was remarkable for its rich tint.

Mr. H. J. JONES, Ryecroft Nursery, Lewisham, sent several Japanese, the most striking of which was Mrs. P. R. Bum, a new one, flowered white with primrose cushion, which the committee wished to see again. Incurved Lady Gormston, a white variety, somewhat resembles C. H. Curtis in build.

CHRYSANTHEMUM SHOW AT DEVIZES.

NOVEMBER 2.—The annual Chrysanthemum Show, held in connection with the Devizes Benevolent Society, took place in the Corn Exchange on the above date, and proved, as it usually does, a decided success. A bazaar is held also, and the proceeds, after paying expenses, are expended in benevolent objects among the poor during the winter months. Mr. THOMAS KING, who has had charge of the gardens of Devizes Castle for many years past, carries out all the staging arrangements in a highly creditable manner, and judging is always commenced at the hour named.

The stalls forming the bazaar occupied one half of the Exchange, the remainder being devoted to the purposes of the flower show. The groups, occupying a space of 60 feet, were arranged in circles down the centre, the best coming from Mr. CLACK, gr. to Lieut.-Colonel C. E. COLSTON, M.P., Roundway Park, Devizes, who has taken the 1st prize for a group of plants for six years past, had plants trained to two or three stems bearing finely developed blooms, forming a bold and striking mass, chief among them were C. H. Curtis and Lord Wolsely as representing the incurved section, and such fine Japanese as Vivand Morel, E. Molyneux, Pride of Maiford, Mrs. C. H. Payne, Madame Carnot, and Etoile de Lyon. Mr. J. HADDINE, gr. to the Marquess de LAVALLETTE, Manor House, Market Lavington, was 2nd, the plants carrying some very fine blooms.

The best nine plants not disbudded came also from Mr. CLACK, admirable decorative specimens nicely grown, and having well furnished heads of bloom.

Cut Blooms.—The leading classes for cut blooms included that for twenty-four incurved, distinct, the 1st prize going to Mr. C. J. Salter, gr. to T. B. HAYWOOD, Esq., Woodhatch, Reigate, who set up some excellent blooms, including Mrs. J. Kearns, M. P. Martignac, Queen of England, Robert Petfield, Violet Tomlin, Princess of Wales, Mrs. Heale, Mrs. R. C. Kingston, Mrs. Coleman, Lord Wolseley, Madame Darier, C. H. Curtis, and Golden Empress. 2nd, Mr. W. G. ADAMS, 59, Clarendon Road, Southsea.

With twenty blooms of incurved, Mr. SALTER was again 1st. With twenty-four blooms of Japanese, the 1st prize being a handsome Silver Cup, given by the Mayor of Devizes, Mr. SALTER was again the fore, staging fine blooms of Mrs. J. Lewis, Charles Davis, A. H. Wood, Mona C. Molin, Mrs. C. Bick, Mrs. C. Orchard, Madame A. D. Chatin, Madame Chénod de Léché, E. Molyneux, Thomas Wilkins, Vivian Morel, Australian Gold, Phœbus; Mr. T. S. VALLIS, Bromham, was 2nd.

Mr. SALTER was again 1st for twelve blooms of Japanese incurved, having in fine character Lady Ridgway, Mrs. C. H. Payne, A. H. Fewkes, M. H. Jacotot fils, Lady Isabel, Duke of York, Madame Zeide, Australian Gold, Australis, &c.; 2nd, Mr. T. ROBINSON, who had Lady Ridgway, Oceana, Lady Isabel, Lady Byron, Ernest Cannell, &c.

There was a class for twelve blooms of Japanese, the competition confined to the county of Wilts, and here Mr. W. ROBINSON came in 1st with fine examples of Madame Carnot, Australia, Charles Davis, Elith Tabor, Mrs. J. Lewis, Beauty of Teignmouth, and M. Chénod de Léché.

There was also a class for twelve blooms of Anemone-flowered varieties, not fewer than six varieties, and here Mr. SALTER again took the 1st prize, having charming blooms of Mr. W. Astor, Owen's Perfection, Mrs. Judge Benedict, Descartes, Minnie Chater, &c.; Mr. W. ROBINSON was 2nd. D.

THE SCOTTISH HORTICULTURAL ASSOCIATION.

NOVEMBER 2. — Another very successful meeting was held on Tuesday last; Mr. TODD, the president, in the chair. Twenty-five new members were admitted. Mr. Harrow, of the Royal Botanic Gardens, was called upon to proceed with his paper on "Pot Cultivation *versus* Planting-Out." The general purport of the lecture may be said to have reversed the title; the lecture being in the main an exposition of the superior merits of the system of planting-out. Mr. Harrow has, within the last two years, as cultivator in chief under glass or sub curator, revolutionised the old pot systems so far, and as fast as may be, in the direction of planting-out; and in the fine ranges of new houses now being erected, ample provision is being made for the further extension of the system.

The exhibits included a fine spray of a superior strain of *Lagerflora rosea*, from Mr. FENTON, Clermiston, Corstorphine. Fine vases of the big *Magnus Daisy*, choice *Mignonette*, and a lovely bunch of General Jacquemont *Roses* gathered on November 3 from Mr. Todd's open garden, Stonybank, Musselburgh. As to the *Roses*, it was stated that since the early October frosts, no fewer than 300 blooms had been cut; and up to October 25, and after a dressing of nitrate of soda, no fewer than 300 to 400 bunches of *Mignonette* had been gathered. A poor sample of out-of-door Grapes was shown from Putney in the far South.

Mr. COMFORT, of Broomfield, Davidson's Mains, had an interesting exhibit of twenty-one different kinds of flowers from the open garden, forcibly illustrating the mildness of the season. D. T. F.

BRIGHTON AND SUSSEX CHRYSANTHEMUM.

NOVEMBER 2, 3. — This was a most successful show. Groups of plants were good, also specimen plants and cut flowers.

Mr. G. MILLS, Dyke Road Nursery, Brighton, won for a large and for a small circular group of plants; each group was arranged very tastefully, and in the premier class a happy combination was made of small but high-coloured *Dracenas*, *Crotons*, and *Caladiums*, placed at the base. Mr. W. E. ANDERSON, gr. to B. PARISH, Esq., Melodia, Preston Park, also won for a well-arranged group.

Mr. J. HILL, gr. to W. CLARKSON WALLIS, Esq., Springfield, Withdean, was a close 2nd in two classes of groups, but was most successful in the specimen plants competition, winning for four standards, four Pompons, four dwarfs, and for a specimen pyramid and standard.

Mr. T. FAIR, gr. to R. CLOVES, Esq., Horsham, won for four pyramids.

A good amateur's group came from Mr. C. F. GILLAM, 75, Waldegrave Road, Preston, and secured one of the Society's Medals.

Cut Flowers.—Twelve competed for thirty-six singles of Japanese varieties, Mr. J. R. HEASMAN winning with a grand lot, the best of which were Madame Carnot, Modestum, Western King, G. J. Warren, Phœbus, and Mr. C. Keyser. Mr. J. STRADWICK, Silver Hill Park, St. Leonard's-on-Sea, was just beaten by Mr. T. DANCY, gr. at St. Leonard's Forest, Horsham, for 2nd place.

Mr. WALLIS, gr. to Mrs. MAWS, Hartfield, was 1st for twenty-four Japanese, Mr. DANCY again following.

Mr. HARRIS, gr. to Lieut.-Col. C. P. HENTY, won for twelve Japanese and for six incurved, while Mr. DANCY, Horsham, won for six Anemone-flowered, and for six reflexed varieties.

Fruit.—For three bunches of white Grapes, Mr. W. Taylor,

gr. to C. W. BAYER, Esq., Tewkesbury Lodge, Forest Hill, won with Muscat of Alexandria, also for three bunches of black Grapes with Alicante and for three bunches of Gros Maroc; Mr. J. GORE, Polegate, winning for three of any black Grape, with good Gros Colmar.

For four dishes of dessert Pears, and for two of culinary ditto, Mr. G. Goldsmith, gr. to Sir E. G. LODGE, Bart., Horsham, won in a strong class; and was also first against seventeen competitors for four dishes of dessert Apples.

COVENTRY CHRYSANTHEMUM.

NOVEMBER 2, 3. — The third annual exhibition took place on the above dates. There were 115 entries. The show was opened by JOHN GULSON, Esq., who, though 84 years of age, gave a most interesting and charming address on the nature of the Chrysanthemum, and its cultivation. The chief prizes for Chrysanthemums were taken by Sir RICH. MOON, G. SINGER, Esq., J. K. STABLEY, Esq., T. BROWETT, Esq., S. LODGE, Esq., A. SMITH RYLAND, Esq., W. HERBERT, Esq., W. F. WYLYE, Esq., and others.

Messrs. B. S. WILLIAMS & SONS, London, showed a magnificent stand of Orchids and Begonias; Lord LEIGH showed a very fine collection of fruit and vegetables (not for competition), and these were artistically arranged by Mr. Martin, his lordship's gardener. Sir RICH. MOON also showed a fine collection of fruit; and the secretary of the show, Mr. F. CURTIS, had a stand of horticultural sundries. The exhibition was a great success.

OPEN CLASS.

The 1st prize for a group of Chrysanthemums (open) was won by a group from Sir RICH. MOON; G. SINGER, Esq., being 2nd.

The best group of foliage plants was also from Sir RICH. MOON.

A. JAMES, Esq., took 1st prize for twenty-four blooms of Chrysanthemums, Japanese; and W. HERBERT, Esq., was 2nd.

The best collection of twenty-four blooms, incurved, was shown by S. LODGE, Esq.; and A. SMITH RYLAND, Esq., was 2nd.

BRIXTON AND STREATHAM CHRYSANTHEMUM.

NOVEMBER 3, 4. — This old established society has again held its annual exhibition early in the season. The quality of the plants, notably the groups, was remarkably good. The cut blooms of the Japanese section were shown in better form than those of the incurved.

Plants.—The class for groups was well contested, the premier award going to a grand exhibit by Mr. HOWE, gr. to HENRY TATE, Esq., Park Hill, Streatham, each bloom being of full exhibition quality, whilst the plants were unusually dwarf, and well-clothed with dark, leathery foliage; nearly all of the plants being in 6-inch pots. The dwarf varieties employed were, *Souv. d'une Petite Amlé*, Vivian Morel, Phœbus, Chas. Davis, Mrs. Weeks, and Wm. Seward. The 2nd prize was awarded to Mr. MURSELL, gr. to Mrs. BURTON, Leigham Court Road, for an effective group, comprising many fine flowers.

The 1st prize for six specimen plants was awarded to Mr. J. WESTON, gr. to D. MARTINEAU, Esq., Clapham Park.

The 1st prize for three plants went to Mr. F. GILKS, gr. to A. MONNIS, Esq., Leigham Court Road, for a fine trio, the variety Col. W. B. Smith being about the best of these.

Cut Blooms.—The 1st prize for twenty-four Japanese was awarded to Mr. MURSELL for a very even lot of flowers of bright colours. The best were Sunstone (new), a soft primrose-yellow; Mrs. Weeks, a fine broad-petalled white; Middle Thérèse Rey, Thos. Wilkins, Phœbus, and Graphic; 2nd, Mr. Poulton, gr. to C. T. CARLEY, Esq., Leigham Court Road.

Mr. HOWE was easily 1st for twenty-four incurved blooms, well-finished and fresh, the best being Globe d'Or, Chas. H. Curtis, Princess of Wales, J. Agate, and Mrs. R. C. Kingston.

The best twelve of Anemone-flowered came from Mr. R. CASE, gr. to E. POCOCK, Esq., Clapham; the best-known old varieties being shown well.

Mr. MURSELL was 1st for twelve and also six varieties of Japanese, distinct, in a strong class.

Mr. MURSELL won again with six coloured varieties, his choice being Modestum, very fine; Mr. HOWE was 2nd with remarkable blooms of Vivian Morel.

The best basket of Chrysanthemums arranged for effect was exhibited by Mrs. STRUGGELL, Brixton Hill, consisting of yellow forms of Japanese in light and dark shades, with suitable foliage, and produced a pleasing effect.

At the annual dinner, held on the evening of November 3, N. N. Sherwood, Esq., presided. He was supported by the Hon. T. Mackenzie of New Zealand, Mr. J. A. Laing of Messrs. J. Laing & Sons, Mr. J. Peed of Messrs. J. Peed & Sons, and Mr. Jas. H. Veitch of Messrs. J. Veitch & Sons, Ltd., with W. Roupell, Esq., the Hon. Sec., and Mr. N. N. Sherwood, the Society's Treasurer. J. H.

SWAINSONIA ALBA AS A BEDDER.—We read in the *Florists' Exchange* of the above plant being employed as a bedding-out plant in Washington. The first experiment was made with plants which were lifted from the greenhouse benches, where they had furnished flowers for cutting during the winter.

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending October 30, is furnished from the Meteorological Office:—

"The weather during this period was fair and dry as a whole, but much fog or mist was experienced at times, especially over England. The fog which prevailed in the Metropolis and its neighbourhood on Thursday was unusually dense.

"The temperature was again above the mean, the excess ranging from 7° in 'England, S.W.' and over Ireland, to 3° over the eastern and central parts of Great Britain. The highest of the maxima were registered towards the end of the period, and ranged from 66° in the 'Midland Counties' and 'England, S. and S.W.' to 62° in 'Scotland, W.' The lowest of the minima, which were recorded on rather irregular dates, ranged from 34° in 'Scotland, E.', to 38° in 'England, S.' and 'Ireland, S.', to 41° in 'England, S.W.' and 49° in the 'Channel Islands.'

"The rain/fall was again much less than the mean. Over the greater part of England there was an almost entire absence of rain, but small amounts of moisture were deposited in the gauge by the wet fogs and dews which prevailed during the latter half of the week.

"The bright sunshine varied considerably in the different parts of the kingdom, but was, as a rule, more prevalent in the east and south than in the west. The percentage of the possible duration ranged from 53 in 'England, S.', 50 in 'Scotland, N.' and 'England, E.', and 41 in the 'Channel Islands,' to 26 in 'Scotland, E.', 23 in 'Ireland, S.', and 18 in 'Ireland, N.'"

POTATOS.

Trade is firm for finest quality and standard colour, but a shade weaker for other descriptions, owing to the continental supply. Hebrons and Snowdrops, 80s. to 105s.; Saxons and Maincrops 75s. to 100s.; Giants and Magnums, 75s. to 85s.; Blacklands, 65s. to 72s. 6d. per ton. Belgium and Dutch Ware, 3s. to 8s. 6d. per bag of 50 kilos. John Bath, 32 and 34, Wellington Street, Covent Garden, W.C.

SEEDS.

LONDON: November 3.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that there were but few buyers at to-day's market, with scarcely any transactions passing. All kinds of Clover-seeds are just now neglected. The prohibitively high prices asked for foreign Tares cause English-grown samples to be regarded with greater favour. Full rates are asked for Blue Peas and Haricot Beans. For Bird seeds the demand is meagre. New Scarlet Runner and Longpod Beans offer very reasonably. Mustard, Rape, and Linseed keep firm.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qr.), for the week ending October 30, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

(Markets carried over to p. xii.)

BOOKS: R. Joyce. *The Art and Practice of Landscape Gardening*, by H. E. Milner (published by Simpkin, Marshall, Hamilton, Kent, & Co., Stationers' Hall Court, London); *How to Lay Out a Garden*, by E. Kemp (published by Bradbury, Agnew, & Co., Ltd., 10, Bouverie Street, Fleet Street, E.C.)—C. A. Webster's *Practical Forestry* (Rider & Son); Grigor's *Arboriculture* (Edmonston & Douglas). There are other more elaborate works on the subject.—C. J. N. *The Orchid Manual*, by B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, would be of service, there being numerous illustrations in its pages.

CARNATION: J. Gachelin. The plant is a prey to the fungus, *Helminthosporium echinulatum*. See answer to Malmaison.

CHRYSANTHEMUMS: W. B. The leaves are mined by the larvae of a minute fly. On the first appearance of the mines in the leaves, the grubs should be nipped with the thumb-nail; any neglect to do this being followed by the disfigurement, and eventually the loss of the leaves. Syringing with Quassia-water during the warm weather, might prevent the flies depositing their eggs on the leaves.

CHRYSANTHEMUM LEAVES INJURED: A. B. The injury has been caused by syringing with some caustic liquid.

CORRECTION.—On p. 369, of vol. xxi of your paper, under the caption "The Testing of New Varieties," there are erroneously attributed to Dr. Liebscher certain statements for which he is not responsible. The article referred to was originally printed as an editorial in *Experiment Station Record*, vol. vii., p. 903, and was based upon compiled records of experiments made at the Agricultural Experiment Station of Illinois. *The Experiment Station Record* is published by the Office of Experiment Stations of this department, and not in Illinois. A. C. True, Director, Office of Experiment Stations, Washington. [The article referred to was taken from the *Revue Scientifique*.]

DOUBLE-FLOWERED PRIMULA: J. Gachelin. When the plants cease to flower, place them in a frame on a spent hot-bed—*couche soudee*—plunged to the rims of the pots, and fill up between, and close round the plants with sphagnum-moss and sharp sand, and keep moist, and somewhat close. Roots will soon push into the moss in great numbers from the stems; the growths should then be detached, and potted in thumbs and small 60's, and treated similarly to Primula seedlings.

DOUBLE LAPAGERIA FLOWER: Crossland Bros. Not perfectly double, but nearly so. By layering from the joint whence these were produced, it might be possible to obtain a plant that would produce double blooms.

MAGNOLIA LEAF: E. B. Of more than ordinary size.

MALMAISON CARNATIONS DISEASED: Malmaison. The plants sent are suffering from an attack of the fungus *Helminthosporium echinulatum*. There is no known cure, the disease commencing in the tissues, and your best course is to pull up the entire plant or plants, and forthwith destroy by burning.

MUSHROOM DUNG: R. S. G. Let this remain in a flat, wide mass on the floor of a shed, after removing the long litter, and well mixing the droppings and short litter together. If it be about 1½ feet deep, it will generate a strong heat regularly all over in a few days, which it should be allowed to do for two days, and then be turned and mixed, and again spread out to heat. This should be repeated twice or thrice, as may be found necessary to get rid of the rank smell, and the tendency in the dung to get very hot, which, if it occurred in the Mushroom-bed would kill the spawn, and end in the drying of the materials of the bed and its consequent rapid cooling. A Mushroom-bed should be made about 2 feet thick, and the spawn inserted when the warmth is at blood heat, and it is not likely to get warmer.

NAMES OF FRUITS.

* Applications to name fruits are so numerous at this season, as seriously to hamper us in the exercise of our editorial duties. They entail an expenditure of time, labour, and money, of which our readers can have little idea. We are most desirous to oblige our correspondents as far as we can, but we must request that they will observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones, just approaching ripeness, and they should be properly numbered, and carefully packed. We do not undertake to send answers through the post, or to return fruits. Fruits and plants must not be sent in the same box. Delay in any case is unavoidable.

A. Fyerley. 1, Annie Elizabeth; 2, Grange's Parnmain.—H. J. Wheeler. Tyler's Kernel.—E. J. 1, Lord Grosvenor; 2, Nonsuch; 3, Court of Wick.—J. Down. Apple Dumelow's Seedling, fine specimen.—T. M. 1, Blenheim Orange; 2, Beauty of Kent; 3, King of the Pippins.—H. C. Blenheim Orange.—Major C. E. Wood. Cat's-head.—C. P. 1, Emperor Alexander; 2, Duke of Devonshire; 3, not sure of.—W. Young. 1, probably from the stock, of no merit; 2, King of the Pippins; 3, Tom Putt; 4, specimen over-ripe.—C. R. 1, Cellini; 2, Ecklinville Seedling; 3, Golden Reinette; 4, Cox's Orange Pippin; 5, Beurre de Capiaumont; 6, Calabasse Bosc.—M. W. 1, Cox's Orange Pippin; 4, Warner's King; 5, Cox's Pomona; 6, Royal Codlin; others not recognised.—A. J. Long. 1, Knight's Monarch; 2, Franc Real.—John Bolam & Sons. 1, Old Winter Parnmain; 2, Scarlet Nonpareil; 3, Hambledon Deutsaus; 4, Gloria Mundi.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—G. H. M. *Euphorbia pilosa*, *Ruscus racemosus* (Alexandrian Laurel).—G. P. *Aster novi Belgie*. We cannot tell the variety. 1, *Chrysanthemum serotinum*.—R. H. G. 1, *Mikania scandens*; 2, *Pellionia pulchra*; 4, *Passiflora*, cannot say without seeing flowers; 5, *Clematis indivisa*.—H. J. *Liverpool*. *Euonymus europaeus*.—S. D. It is very difficult to name such scraps; 1, probably *Cupressus macrocarpa*; 2, *Juniperus excelsa*, probably; 3, *Picea orientalis*; 4, with cone, *Picea Glehnii*; 5, variety of Yew.—W. O. W. We suspect that the plants you sent us a month ago were not named owing to the specimens being poor ones. Several of those before us are also insufficient for determination. 2, *Epiphyllum truncatum*; 3, *Abutilon vexillarium*; 5, *Acacia* species.—W. H. D. 1, *Euphorbia pilosa*; 2, *Polygonum* sp., not a fair specimen; 6, *Carex japonica variegata*. The Asters should be sent to a nurseryman who grows these plants largely.

ORCHID FLOWERS DAMPING: Paisley. In towns, fogs cause Orchid blooms to wither; and even in the country they go in the same way during continued sunless weather.

VICTORIA MEDAL: J. H. No doubt there are very many deserving gardeners and others, but we cannot undertake to discuss the qualifications either of actual or of possible medallists.

VINES AND MEALY BUG: R. S. G. See our calendar for "Fruits under Glass" in present issue. You might use the XL All Vaporiser during the winter of good strength, and during the summer of less strength. Clear out the upper crust of the border, replacing it with new loam, crushed bones, lime rubbish, charcoal, making it quite firm by tramping, then apply a mulch of dryish manure from the stables. Afford a good application of water if the border on examination is found to be dry. Besides carrying out the above operations, you should limewash the walls, do any necessary painting of the woodwork, or failing the need for this, scrub it with soap and water, doing the same to the hot-water pipes, about which mealy bugs are sure to harbour.

WHITE CAPE ERICAS FOR FLOWERING AT THE SEASON: B. H. W. There is no pure white flowered Cape Erica flowering in the winter. E. *hyemalis* flowers in early winter, and E. *Willmoreana* in late winter and spring. Neither is quite white.

THE

Gardeners' Chronicle.

SATURDAY, NOVEMBER 13, 1897.

THE PINE-APPLE IN QUEENSLAND.

THE constitution of the Pine-apple in this colony is very different to what it is under artificial cultivation in the old country, and affords an instance of how a plant may become tender when cultivated under glass, and with artificial heat. The heat of the ground and the atmosphere in Queensland is, throughout a good part of the year, as high as is found in Pine-stoves in England; but it is during the months June, July, and August, which are considered the winter season, that the difference is greatest, for during July we sometimes see slight hoar frost for two or three mornings—indeed, to give a comparison, we have had sufficient to blacken the leaves of Vegetable-Marrows and sweet Potatos, but it did not seem to affect the Pine-apple plants in the least degree. During the winter they (the plants) assume a reddish tint. We cut fruit almost every day, and, as far as I can see, we shall not be out of fruit this winter, for they are in various stages at the present time (July 9), some ripening, and some showing; but it is in December and January that there is a glut of Queens, the smooth Cayenne following these. The foliage is firmer and harder than that of house-grown plants, and as evidence that this is so, the crowns may lie kicking about on the ground, with the sun shining on them at 160° or 170°, and then grow if stuck in the ground. Here the plants never have the fine appearance they have under glass, for the ploughman, with his horse-plough or scarifier, often breaks the leaves and twists the plants about. Even around Brisbane, which is 625 miles further south, they do very well; but before winter the farmers go through the fields and put a wisp of hay over the fruit, to keep the frost off them, for although frost does not destroy the leaves, it spoils the fruit.

It is not much over thirty years since the town consisted of the dilapidated tent of the pioneer, Mr. McKay, who was the discoverer of the river, and after whom the town was named; but it was not long after that when Pines began to be grown by another of the pioneers, who is now dead, and if an old country grower could drop down on the spot, and see the soil, it would be a bit of surprise for him, for the land consists entirely of sand, apparently as pure and clean as the sea-beach at Brighton, and but a few feet above the level of the sea, and oftentimes flooded by salt-water. He grows them in rows 13 feet apart, and I have heard it said that he had Pine-apples 13 lb. in weight, but I have not seen any of a greater weight than 9 lb.; but then they had been cultivated on the same land for several years. The first time I visited his grounds, after I came out here, he

pointed to the fruit of what was the third crop; he said I always got two crops, but this is the first time I have taken a third. I have seen the third suckers fruiting. It might be supposed that planted at 13 feet between the rows was a waste of land; but as it did not cost him anything, and for a good many years afterwards was not worth more than 2s. 6d. an acre, with six years in which to pay that sum, he could afford to be liberal in the use of it, but he told me he had tried them at various distances, and had found that he got the greatest weight of fruit under a wide-line system. No manure was applied, for the very sufficient reason that there was not any to apply. This grower got a good price for his Pines at Sydney; and as time went on the town grew in populousness, and he got good sale for them at Mackay, which induced other persons to cultivate the fruit, with the result that there was soon a glut, and prices went so low that it was not worth while to cart them into the town. A gentleman who went into it largely about 16 miles out on the sea coast (sand again), saw that he had overdone it, so he got as many pigs as he could to eat them—still then thousands of the fruits rotted on the fields. It was proposed to raise a company to can the fruit in the neighbourhood, this grower contracting to sell his Pines at 1d. each, and it would have paid him at that price, but the scheme fell through. The Trinidad Pine attains the largest size with me (8 lb. the heaviest), but Reine Pomare (a Queen) is by far the finest flavoured variety. Certainly the flavour is richer here when well ripened on the plant than it is in the old country, but the intense sunshine and dry atmosphere for a good part of the year may account for this.

No doubt many of your readers will consider that frost and clear sand are conditions not very favourable to Pine-growing; the suggestion that the sand contains disintegrated coral which abounds on the coast may have something to do with the growth; it is a supposition only, and may or may not have anything to do with our success—but the frost we can understand, and might come to the conclusion that it was impossible to grow Pines under such conditions. Although we have not seen any hoar inside the nursery, it has been seen on the grass alongside the Lagoon and in the horse paddock this winter, and yet the Pines are in all stages of growth and fruiting; one cannot help coming to the conclusion that artificial cultivation renders plants tender. The Vegetable-Marrows, I think, is an illustration; it grows and bears well till killed by frost in England, and yet it is evident that when the Pine-apple and it are grown under the same conditions, the Pine is the hardier of the two. It is very seldom that the temperature here in summer rises above 100°, it has not done so for the past five years, 96° to 98° is about the highest, so the Pine and the Pumpkin have the same chance.

I noticed in the *Gardeners' Chronicle*, May 15, 1897, in "Notices to Correspondents," some remarks on the Papaw, and I see its fruiting is not very frequent, and that is rather surprising to me, seeing the enormous weight of fruit they bear here in a season, would make them worth cultivating in England, and as the fruits ripen, one, two, or three at a time, a tree would continue in bearing for a long time; but I expect the quality of the fruit would not be esteemed. ~~Many people~~ here are fond of them, and the grower them; it is only by rid and sugar with them

that I can eat them. I plant them out in a row 3 feet apart, and at this distance they will flower when about 3 feet high; the males and females can then be distinguished, the males that are not wanted being then cut out, and the females thinned out to 15 feet apart; the plants fruit well for two years. The variety that I grow is called the New Papaw, it is distinct from Papaya, in being dwarfer and branching, and as the plants are all grown from seed, they differ a good deal in sweetness and flavour. D. Buchanan, State Nurseries, Mackay, Queensland.

NEW OR NOTEWORTHY PLANTS.

ACANTHOPANAX SESSILIFLORUM.*

ALTHOUGH, as the references show, this cannot be considered a new plant even in gardens, yet it is comparatively little known. We met with it in fruit lately in the nursery of M. Lemoine at Nancy, and with the predatory instinct of the botanist, secured a specimen for the benefit of the readers of the *Gardeners' Chronicle* (fig. 100, p. 339). It is a handsome shrub, presumably perfectly hardy, with long-stalked, palmately three-lobed leaves, the lobes leathery, dark green, broadly lanceolate, and tapering at each end, finely serrate at the margins. The flowers, which we did not see, are in globose heads, and are succeeded by black berries, each the size of a small Pea, and reminding one of Privet-berries, or still more of Ivy-berries. The shrub is a native of the Amoor region, of the coast of Manchuria, and of North China. M. T. M.

TAMARIX HISPIDA VAR. KASHGARICA.

We met with this shrub flowering freely at the end of September in the nursery of M. Lemoine at Nancy. It is much more glabrous than the true *hispida*, of which there is a good figure in the *Revue Horticole* (1894), 353, but the structure of the flower is the same. The Tamarisks as described are rather numerous, but the distinctions are difficult to see. Naturally they grow in dry, rocky localities, or on ground impregnated with salt. It is on this account that the common Tamarisk does so well by the seaside.

TWO NEW NEPENTHES.

N. Jardinei, Bailey, n. sp. (after Frank L. Jardine) Stems several, rather stout, arising from a hard, knotty rhizome, 2 to 3 or more feet high; not climbing, sometimes branched, clothed with leaves mostly bearing pitchers; the young growth more or less clothed with soft hairs, the shorter ones of which are usually stellate, the longer ones frequently simple. Leaves decurrent, and slightly stem-clasping; petiole 2 inches long, winged; lamina 8 inches long, and from 2 to nearly 3 inches broad in the middle, tapering towards each end; midrib at first purplish-red, longitudinal nerves on each side of midrib usually six; the narrow portion of stalk of pitcher about 6 inches, without the loop of *N. Kennedyi* (F. v. M.); pitcher 5 to 7 inches long, 1½ inch diameter near the top, enlarging in the lower half to about 2½ inches, with numerous prominent longitudinal nerves and reticulations; anterior ribs with narrow red wings; orifice wide, and arising towards the spur; peristome narrow, about 1 line broad, with numerous transverse veins; posterior spur recurved; operculum elliptical, about 2 inches long, with numerous various-sized circular glands on the inner surface; inside of pitcher more or less spotted or stained purplish-red. Racemes dense, 4 to 8 inches long in the males, but shorter in the female racemes; male perianth of four oval segments, about 3 lines long, reflexed upon the pedicel, united, and forming a cup at the base; staminal column about the length of the perianth segments, head of anthers about 1 line

* *Acanthopanax sessiliflorum*, Seemann in *Journ. Botany*, v. (1867), 299; syn. *Panax sessiliflorum*, Ruprecht and Maximowicz, 1857, and Maximowicz, *Primit. Flor. Amur.* 131; Regel, *Garten Flora* (1862), t. 369, p. 238; *Panax sessilifolium*, C. Koch, *Dendrob.*, l. 673.

diameter; female perianth like the male, stigma sessile; capsule coriaceous, $\frac{3}{4}$ inch long, four-valved, each valve crowned by a lobe of the stigma. Hab., Somerset, Cape York Peninsula, Frank L. Jardine.

N. Rowan, Bailey, n. sp. (after Mrs. Rowan, a painter of Australian flowers). Pitchers, when fresh, beautifully marked with reddish-purple, about 6 inches long, shortly and abruptly curved at the base, from which it widens upwards, attaining a width at the top of about 3 inches, prominently marked on the outside by oblique parallel nerves and reticulate veins; anterior ribs hard, scarcely winged, much nearer together than in *N. Jardinei*; orifice very wide, posterior spur flat, tomentose; peristome 3 or 4 lines broad, with close transverse veins; operculum nearly orbicular, about $2\frac{1}{2}$ inches in diameter, with numerous circular glands on the inner face. Hab.: Somerset, Cape York Peninsula, Frank L. Jardine (Bailey, in *Queensland Agricultural Journal*, Sept., 1897.)

MARKET-GARDENING IN LINCOLNSHIRE.

Boston and its district is famous for its market-gardening: a very extensive acreage of the best land is now principally employed for the growth of market produce; the farmer class is taking to it, and cultivating crops of ordinary vegetables in place of low-priced cereals. This practice appears to be increasing throughout the Midland districts, where the soil is suitable, and an outlet is found for a great deal of the produce in the markets of Yorkshire, Newcastle-on-Tyne, &c. Occasionally, when there is a scarcity in the London markets, great quantities are sent there. The deep fertile loams about Boston, lighter in some places than others, are found very suitable for the culture of early Potatoes, especially the Ashleaf, and from one railway-station near to Boston enormous quantities are sent away soon after midsummer. It is the practice with many to plant three rows of Potatoes, leaving space for a line of Celery, the Clayworth Prize Pink being that principally grown; the plants are put out early, and as soon as the crop of Potatoes is lifted, earthing-up commences. The Celery plants are put out during the month of May. Other growers plant between each row of Potatoes some description of Winter Greens, such as Brussels Sprouts, Savoy Cabbages, or Veitch's Autumn Giant Cauliflower, and sometimes the Early Drum-head, or one of the garden varieties of Cabbage.

Spring Cabbages are another staple vegetable, a very large acreage of land being devoted to them; the leading sorts are Early Rainham, Early Offenham; and occasionally selections from the Nonpareil type, with Ellam's Early, or a kindred form, are grown in small breadths on lighter warm land somewhat sheltered. Seeds are sown from the middle to the end of July, to the first week in August. The land, having been manured for Cabbages, is planted with Potatoes for a late crop, or with Veitch's Autumn Giant Cauliflower as soon as the Cabbage crop is cleared.

Carrots are also largely grown, the intermediate types mainly; and there are moderate breadths of Beet and Parsnips; but it would appear that the Jerusalem Artichoke is becoming increasingly popular and there is a decided extension of its culture—the white-skinned variety in particular. As in Bedfordshire, so at Boston, Cucumbers and Melons are grown between the rows of early frame Potatoes, and as soon as the Potato crop is cleared, the bine is allowed to extend.

A considerable acreage is given up to Peas for picking for market; the leading varieties are Earliest of All, Improved Sangster's, William Hurst, English Wonder, American Wonder, Prince of Wales, Prize-taker, Telegraph, Fortyfold, an improved stock of Gladiator, Veitch's Perfection, and Duke of Albany. Good remunerative prices are obtained for the early and second-early varieties. Broad Beans are also a leading crop; the leading varieties being the white and green Harlington Windsor, these appearing to be most in demand in the markets.

Throughout Lincolnshire, on the soils found most

suitable for Peas, very large breadths of blue Peas are grown for boiling purposes, it having become a very important farm crop; the leading sorts are Belman's Imperial and Harrison's Glory. R. D.

BOTANISING IN SOUTH-WEST AFRICA.

THERE is no letter-box here "round the corner," but we have to ride on horseback about thirty-five hours as far as Keetmanshoop to post or to fetch letters. In Swakopmund, though we landed there goods during twelve days, I was so busy botanising in the Swakopbed, with paper-drying, changing, labelling, and such work, that I did not find time to pay my visits to all the store-keepers and officials. But my working there was very successful. I collected about 140 plants in flower or fruit, among them, I believe, some are new as you will see when Professor Schinz publishes them in the *Journal of Botany*. I went in the Swakopbed with a soldier to a distance of 16 kilometres up, as I wished to see the Ana-tree, a kind of Acacia. In very swampy places in the said river-bed grew in quantities an Apium, which may be our common European Celery.

Four or five hours' voyage brought us to Walfisch-bay, a very sheltered, but very sandy natural harbour. The settlement is placed in a still more desolate landscape than Swakopmund. I walked to Sandfontein, where I found the very curious Cucurbitacea *Acanthosicyos horrida*, a bright-green, leafless, but excessively spiny plant, with upright branches 4 ft. high, just with buds, flowers, and fruits, in all stages of development, the largest as big as a head, and covered with short, thick, fleshy spines. It is a perennial, growing in the poorest sands, and luxuriating with a little dew. I found nothing else in Walfisch-bay except the common weed, *Nicotiana glauca*, and in what quantities! In the Swakopmund, too; thirty-five hours more travelling, and we were at Lüderitsbucht. Apparently only brown barren rocks, without any vegetation; at least, a mile away from the shore. On shore I was quite astonished to find in every cleft of the granitic rock the most interesting forms of the vegetable kingdom, which kept me in that place for ten days. All the rocks around Lüderitsbucht form together an enormous natural "succulent rockery." There are three kinds of very nice-flowered *Pelargonium*, about ten species of *Mesembryanthemum*, two *Crassulas*, one *Septas*, one *Sarcocaulon* (Schinz says in his excellent book S. Burmanni, but it is a perfectly different one), one *Euphorbia*, half-a-dozen *Zygophyllaceae*, one frutescent *Umbellifer*, three yellow-flowering *Compositae*, with quite white woolly and fleshy leaves; and a very small succulent grass, *Aristida subcaulis*, besides a host of most interesting plants whose relationship I do not yet know. I have some reason to think the *Septas* a very curious minute *Mesembryanthemum*; and a precious *Stapeliaceae*, perfectly new plants, as they are so wonderfully accommodated to the surrounding stones, that only one with very practised eyes could discover them.

The travel by oxen-wagon from Lüderitsbucht to Inachab in sixteen days was for me a travel through Paradise (for other more reasonable people through a desert!). I must admit that the first three or four days through the endless sands are to most people horrifying, but then the country and the vegetation becomes surprisingly rich and varying. I collected not half of the flowering plants which I saw. I have more than 200 species together, and we are now in the middle of winter. The first few dozens of *Aloe dichotoma*, the most stately plant of the whole genus, I found first in the neighbourhood of the Tsehirubpass. It is a tree as much as 15 to 20 feet, with a stem often 2 feet diameter at the base, and more than 1 foot thick in the height of the branching.

In Gubub, at a height of about 1100 meters, how great was my joy! as I found *Sutherlandia frutescens* and *Aloe striata*, and two other *Aloes* which I did not know; one possibly new *Crassula*, growing only in places where the sun never penetrates! two *Seneciones* of

the *Kleinia* section, *Cotyledon orbiculare*, and *C. sp.* a very curious species, with leaves similar to those of a *Kleinia*, and growing on wet rocks. Around Gubub I noticed about sixty frutescent *Compositae*, each worthy to be introduced into S. European gardens. Under overhanging rocks the small leaves (flat, adpressed to the soil) of a *Massonia*, the large leaves of *Hemanthus*, a single flowering specimen of a fine *Antholyza* (quite like *A. Schweinfurthii*), two species of *Stapelia* (which I cultivate here until I have seen them in flower).

In Zachanebas there were enormous specimens of *Aitonia capensis*, tree-like bushes, with stems 18 inches thick at the base, and here in Inachab I have four specimens of this plant directly in front of my windows. In the Ugam valley I found the largest specimen of this perhaps finest of all S. African shrubs; this specimen carried at least seven full grown *Misletos*, a plant much like *Viscum album*, but in all parts smaller, and the berries yellow, not whitish. Thousands of the small berries, which had fallen off, stuck on the bark of the lower branches, where I could see them in all phases of germination, without the aid of birds. I found also number of berries germinating on the green stem of the mother *Misletos* itself. Two very fine species of *Loranthus* are very common upon *Acacia detinens* (the *Waitabit*), *horrida*, *Parkinsonia* species, and other shrubs. The flowers much resemble those of a red flowered *Lonicera*; and some *A. horrida*, were so full of those parasites, that they had broken down.

The *Acacia horrida*, growing in great quantity, is suffering much from the larvae of a goat-moth. I found stems $1\frac{1}{2}$ foot thick converted, from the base up to the finger-thick branches, into sawdust. The beautiful "Kamuldoorn" (*Acacia Giraffe*) does not seem to have such dangerous enemies as the "Doornboorn," at least, not to the same extent. Its pods are of such a curious construction, that I cannot compare them with any other species of *Acacia*. The very large seeds are embedded irregularly in a very thick mealy substance. The oxen are very fond of these pods, and the consequence is, that on garden-land, where ox-dung is used, thousands of young *Acacia Giraffe* spring up, as here at Inachab. The Ebony-tree (*Euclea pseudobenum*), a beautiful tree, with gracefully hanging thin branchlets, and black berries in the axils of the leaves, is very common here on the borders of the river-beds, and its perfectly black and very hard inner-wood may one day become an article of export, provided we get the long-promised railway from Lüderitsbucht to Keetmanshoop. Many square miles of land round Inachab are literally covered with an *Euphorbia* sp. (belonging to the same group as *E. Schimperii* and *E. rhipsaloides*), which look like enormous brooms. The green bark of these nasty plants is covered with a kind of vegetable-wax, which can easily be collected. This might also become a source of revenue to the intelligent farmer.

The *Eriobotrya japonica* seeds, which I collected shortly before leaving La Mortola, are germinating now. I saw a considerable quantity of *Ailanthus glandulosa*, which may be used as a shade-tree, for timber, and the leaves if possible as fodder for oxen. A little later on I will write you about my experiments with Vine-seed, and other discoveries which I shall make the next few months. Dinter, Inachab, near Keetmanshoop, Great Nama-land.

HOLMEWOOD, CHESHUNT.

THE interesting garden of J. T. Bennett-Poe, Esq., contains a large number of rare and pretty plants, each of which is specially tended, and various devices and shifts are resorted to for the benefit of reputed difficult subjects, whose interests are allowed to encroach on the primness usually affected in gardens of moderate size.

ORCHIDS.

The comfortable span-roofed Orchid-houses contain a very fine show of flowers of the very best quality, borne on plants in vigorous health, all indi-

the skilful treatment of Mr. Downes, the owner at Holmewood, and the interest taken in one and all, by their owner. In the first warm weather a number of well-bloomed plants of *Cypripedium*, *Spicerianum*, and a grand lot of *Dendrobium* *Schroderianum*, chiefly of the light-

lip, which in the different specimens varies from chrome-yellow to orange. Also in bloom are *Vanda* *Sanderiana*, *Coelogyne* *Micholitzii*, *Oncidium* [*Papilio*], *Miltonia* *Rozeii* *alba*, *Aërides* *Lawrenceae*, *Calanthe* *× Clive*, *Cypripedium* *× Perseus*, *C. × cardinale*, *Vanda* *Bensoni*, *Cypripedium* [*Victoriae* *Marie*], and a

orange-scarlet flowers; *Anthurium* *Andréanum* and *A. Scherzerianum* display their dark scarlet spathes; and some of the *Nepenthes* are well-furnished with "pitchers."

In the next house the most prominent plants in flower are *Vanda* *cœrulea*, a pretty group of *Pleione*: *Wallichiana*, *maculata*, and *lagenaria*; some very fine *Laelia* *Dayana*, *Cattleya* *Dowiana* *aurea*, *Dendrobium* *aureum*, blooming profusely on the current year's growths; *Coelogyne* *ocellata* *maxima*, *Zygopetalum* *intermedium*, *Lycaste* *Deppel*, and a singular bluish-white *L. Skinneri*; *Cypripedium* *Arthurianum*; and at the end of the house two very fine *Sobralia* *xantholeuca*, and one of *S. macrantha* *alba* promise well for bloom.

In the third house is a good show of *Odontoglossum* *grande*, and a few other species, and here are a quantity of splendid plants of *Cattleya* *citrina*, which bloom so profusely at Holmewood. During the heat of the summer, and until a fortnight ago, the plants were suspended from the sides of the staging, and hang over the shaded walk, a position which suits them admirably. During the winter they are suspended near the glass of the roof. In this house is a fine specimen of *Nerine* *× Mauselli*, with ten spikes of its showy carmine crimson flowers; the pretty *N. Novelty*, and other *Nerines*; also *Cyrtanthus* *lutescens*, *C. McKennii*, *C. parviflorus*, and other *Amaryllids*; and the richly-coloured *Begonia* *Freesei* incomparably illustrated from these gardens in the *Gardeners' Chronicle*, December 7, 1895, p. 681.

Also in bloom is a very fine batch of the best form of *Laelia* *pumila*, *Epidendrum* *× O'Brienianum*, *Trichosma* *suavis*, *Cypripedium* *Charlesworthi*, *Oncidium* *Forbesii*, *Cypripedium* *× Lecanum*; a fine batch of varieties of *C. insignis*, of which the *C. i. violaceo-punctatum*, *Chantini*, and *nitens* are especially good.

The other plant-houses have numerous pretty species not generally met with in gardens. Indeed, it is towards these rather than towards the ordinary run of showy flowers that Mr. Po's fancy leans. In one house the *Lapageria* *rosea*, *Nash* Court variety, and the *L. alba*, are well in bloom; *Campanula* *Vidali*, and other uncommon plants are in flower, and a batch of *Disa* *grandiflora* flourishing.

In one of the vineries are some sturdy *Dendrobiums* at rest, some of them having been ten years in cultivation. Here, also are in flower *Cestrum* *aurantiacum*, *Swainsona* *galegaefolia* *alba*, *Calceolaria* *Barbidgei*, *C. alba*, and the pretty Myrtle-like *Eugenia* *australis*, covered with pretty white flowers.

In another house are several kinds of *Nerines* in flower, *Gerbera* *Jamesoni* in bud, *Toxicophloeæ* *spectabilis*, and other flowering shrubs, and in the open garden beside the plant-houses are huge masses of *Crinum* *Powellii*, *C. P. album*, and many other fine plants, which in their season have given a great show of blooms.

CANADA IN COVENT GARDEN.

You ask me to state briefly what is being done by the Canadian Government in assisting to develop Canadian trade with Great Britain in agricultural products. I will endeavour to give you some of the general details and the outlines of our methods.

As you know, we have in Canada in connection with the Federal Government a Minister of Agriculture. The Hon. Sidney Fisher, who holds the position, is a practical farmer. He is thoroughly interested in everything which tends to promote the success and prosperity of the tillers of the fruitful soils of Canada, and realizes that the corner-stone of our national wealth rests largely upon agriculture in its various branches. Associated with him in the department is Professor J. W. Robertson, Agricultural and Dairy Commissioner, who has done as much as or more than any man in Canada by his earnest efforts and faithful service for many years in the work of the department.

As the result of the interest taken by the Government of Canada along this line, we have our agricultural colleges, our experimental farms scattered here and there over our vast dominion, our dairy schools, our

FIG. 100.—*ACANTHOPANAX SESSILIFLORUM*: BERRIES LUSTROUS BLACK. (SEE P. 337.)

ed type, some of them having nearly white and petals. Here, too, the *Calanthes* are grown, and are sending up numerous spikes in the display throughout the winter. Suspended overhead are several splendid specimens of *Obidium* *formosum* *giganteum*, with their large white flowers, bearing a yellow blotch on the

plant of *Cypripedium* *Chamberlainianum*, which, as an imported plant, opened its first bloom in April, 1895, and produced the twenty-seventh flower on the same scape in October, 1897, having been continuously in flower for thirty-one months. Of plants other than Orchids in this house, several fine plants of *Costus* *igneus* have a brilliant display of dazzling

travelling dairies, our farmers' institutes, our fruit and dairy associations—all of them educational in their character, and disseminating knowledge, gained by scientific and practical means, among our people. Canada, with its rich agricultural fields, its boundless prairies, its orchards and vineyards, its vast forests, and great mineral wealth still unexplored, is capable of supporting many millions of people; and, with its varied soils and climate, can produce everything essential to the wants of mankind—and of a very choice quality.

In consequence of our situation alongside of a nation with unfriendly and ungenerous tariffs, the Government have realised the importance of aiding in some tangible way the placing of Canada's surplus productions upon the market of Great Britain in the best possible condition. With this purpose in view, State aid has been granted in the way of a thorough cold-storage system for food products—such as poultry, eggs, creamery butter, meats, and fruits—conveying them from the points of production until they are placed upon the markets of this country. The Government are aiding and encouraging the building of cold-storage warehouses, the running of cold-storage cars to the steamships, and have subsidised this season some seventeen steamers running from Canada to the ports of Great Britain, in order that Canadian productions—which have hitherto been considered of a perishable nature because of the want of these transit advantages—may be placed upon the tables of the consumers of this country in a fresh and sweet condition, fully equal to the productions of any country.

The Canadian Government is also this season making some experimental shipments of Pears, Peaches, Plums, Grapes, and Tomatoes. The first shipments to reach England were not altogether satisfactory, the result very largely of our inexperience; but I am pleased to say that the shipments now arriving are in fine condition, and will ultimately prove a grand success. The consignments by the steamship *Gerona* are being sold at Covent Garden Market by Messrs. Garcia, Jacobs & Co., who are acting for the Government in London.

In conclusion, let me say that I trust that the people of the grand old motherland will give her colony a preference, if no more, in our exports to this country, all things being equal. This much we as Canadians do claim, and look forward to in the near future, that the consuming millions of this great country should be supplied by the people and from the soils of the colonies, instead of buying their food from foreign nations that are hostile to England, not only in tariffs, but in sentiment and sympathy. *W. T. Crandall, Agent, Canadian Department of Agriculture, in "Canadian Gazette," Oct. 23, 1897.*

FLORISTS' FLOWERS.

THE HERBACEOUS CALCEOLARIA.

VERY seldom do we see well-grown plants of the above in private gardens, though few if any flowering-plants make a finer show, and last such a length of time as the Calceolaria. One batch alone I have had in flower for fully six weeks. Where there are large conservatories, the Calceolaria is as indispensable a plant in the spring months as the Chrysanthemum in the autumn, not for cutting purposes certainly, but for a display in the pots, and in this respect it has no equal at that season.

I generally sow the seed (which should be secured from a trustworthy source) about the end of July, in shallow pans filled with light sandy soil, thoroughly soaking the soil with water before sowing the seed. The seed must be carefully distributed thinly over the surface, and barely covered with a sprinkling of silver-sand, a sheet of glass, and a covering of brown paper, or a tile put over each pan, and they are put into a cold frame. In the course of three or four days the plants appear, and the pans should be placed near to the glass, removing the paper, but allowing the glass to remain over the pans for a few days longer. Should the soil require water, the pans

must be sunk to half their depth in a pail of water, and the water allowed to penetrate the soil almost up to the surface, water applied at this stage with a can causing damping. The seedlings may be pricked-off when two true leaves are made into larger pans or thumb-pots, using a compost of loam three-quarters and leaf-mould and rotten cow-dung, with a dash of silver-sand, placing a layer of dried cow-dung over the crocks. In the course of a month the plants will be ready for potting, using good yellow loam and cow-dung only, with silver-sand in the same proportion as before, but in a coarser condition. Over-potting must be avoided, small shifts and often being the best practice, the time and labour in doing this being amply repaid; pot firmly, keeping the bottom pair of leaves well down on the soil.

I have grown the plants for some time now in a large hip-roofed pit, fixing the stage so as to allow the plants to be within 6 inches of the glass, thus securing dwarf, sturdy growth. Under the stage is a large water-tank, and the moisture arising from this body of water seems to benefit the plants greatly. A cool, shady house with plenty of moisture, and an occasional dewing overhead with the syringe, is what is required by the Calceolaria during the growing season, never allowing the soil to become dry, and affording air whenever the weather is mild enough to permit this to be done. Fire-heat should be avoided as much as possible, merely warming the pipes so as to keep out the frost in severe weather. Sunshine in the early spring strengthens the plants, but as it increases in power shading must be used. A good size of pot for flowering the plants in is a large 32, a useful size if the plants are used for in-door decoration. The plant can be grown of large size in 24's, but then stopping is required. As the flower-spikes begin to throw up, the plants should be removed from the pit to the greenhouse. The flower-shoots should be neatly staked out, otherwise they fall over the sides of the pots, having an untidy appearance.

Weak applications of manure may be given as soon as the flowering-pots become filled with roots, and as the flowers open, the application of water should be very carefully carried out, too much water causing the flowers to become spotted, and damp-off. The plants must be fumigated once a fortnight, whether green-fly be observed or not. *R. N.*

CHRYSANTHEMUM GOSSIP.

(Continued from p. 333.)

MR. H. J. JONES'.—There is always much interest afforded by an inspection of the Ryecroft collection of Chrysanthemums, for all of the plants in it represent new varieties. We use the term in the comparative sense, and do not mean that they are all this or last season's novelties. Old sorts, however, that do not need to be further "tried" find no place in the show-house, and such, for instance, as Sunflower are only grown for stock purposes. When so many novelties are grown, a few of which are good, and others good for nothing, it must prejudicially affect the general display; yet there is a capital show of blooms. Mr. Jones tells us incidentally that on Sunday, November 1, about 1600 persons inspected the plants—a fact that was turned to account in favour of the Gardeners' Orphan Fund. In the principal house one is soon attracted by a few of the novelties already partially known, such as Western King, which was sent out last year jointly by Mr. Jones and Mr. Davis, of the Framfield Nurseries. Like Simplicity, it is of American origin, and both are white, slightly incurved Japanese varieties. The differences between the two are not very great, but Simplicity is a purer white, and its petals are less broad. Western King does capitally at Ryecroft, in every conceivable manner, late struck cuttings, as well as the more cared-for specimens, bearing plenty of good blooms. Mrs. Richard Jones, another white Japanese of much depth, and one of Mr. Jones' seedlings, is better known. Then there is H. J. Cutbush, a fine deep chestnut-coloured flower; Pride of Exmouth, one of the very best of Exmouth-raised Chrysanthemums; and Mrs. "Oporto" Tait, a

good yellow Japanese incurved of Messrs. Cannell's. After examining a few such recruits that have entered the ranks, but have still to prove themselves, we are attracted by numerous seedlings and continental novelties not hitherto observed. The capital market variety, Niveum, has sported, and there, under the name of Pride of Ryecroft, is displaying yellow blooms that deepen in colour as they age, and, apart from colour, are of the same character as Phœbus. If it proves as remunerative to market cultivators as Phœbus has done, it will be very valuable. Crown of Gold (Shea), sent out last spring, is very pretty; the name describes the flower, which is colour is true golden-yellow, while the centre of the flower, which is distinct in appearance, suggests a crown. Miss Shea (1897) is a yellow Japanese with slight green shade, as we saw it, and in shape and build reminds one of Avalanche. N. C. S. Jubilee (Calvat) is a fine incurved Japanese of faint rose-lilac colour; the apex of each floret is toothed, and some of the florets are very slightly hirsute. One of the most distinct flowers we saw was that of Mrs. H. Garrat Cumines (Jones). The florets are rather long, narrow, quilled at extreme base, and in those earliest produced, twisted also in various directions. It is rose-coloured, and though not an exhibition flower, is very pretty.

A pure Japanese is Frau Agathe Hesson (Jones), remarkable for being a bright, clear rose-colour, and the flower of good size. Then there are two French raised varieties in Emile Nonum, and President Nonum. The colour of the first named is suggestive of G. C. Childs, with bronzy-buff reverse, and the latter is a true buff Japanese incurved of considerable size and value. Madame Bruant has been certificated this season already, and described several times. It has a distinct and most beautiful appearance, the base being pure white, and the wide florets mauve-coloured towards apex. Vivian Morel has increased its reputation for sporting by producing a variety about midway in colour between the type and Charles Davis. This is named Lady Hanham, and different persons see in its colour tints of yellow, mauve, pink and lilac—it is really very pretty. While speaking of sports, we may mention the name that Mrs. Harman Payne's variation is known by, viz., Mrs. G. W. Palmer—it is a more pleasing tint of colour than the type. Master H. Tucker, a Japanese incurved of deep brown crimson and chestnut reverse, is already in some collections. The ladies may have another green-flowered novelty in Madame Edmond Rogers, and if a pale green flower is ever to become popular, this one is likely to do so, for the flower and florets are good. There are many other novelties in the Japanese section to be seen at Ryecroft, which we must pass on this occasion; but a seedling of the present year calls for the last word. There is but one plant of this variety, R. H. Pearson, with three blooms upon it, and it promises to be a first-class buttercup-yellow Japanese, deeper in colour than Edith Tabor, or any yet sent out.

Of incurveds there seems to be more novelties than for several years past. Mons. Desblanc, a reddish-rose flower, was seen last season occasionally; but in Chrysanthemum Bruant we have a novelty that promises to become a first class back row flower that will need very little preparation for the exhibition-board. The plant is apparently rather tall, and the large flowers are bronze coloured. "*Mum.*"

AT EARLSWOOD.

There is probably no finer or more extensive trade collection in the country than Mr. W. Wells has at Earlswood. Certainly few growers are more enterprising, or strive to secure a more varied collection of the novelties, home and foreign. The greater portion of the huge collection is housed in a big span 160 feet by 30 feet, thus giving ample room and an abundance of light and air. Out of so many new ones there is a large number that, whilst very beautiful, are not likely to make show-flowers; but there are some of much excellence. Then there are many late-struck plants blooming finely, and these furnish an admirable object-lesson in securing desirable dwarfness. Quite new of Japanese is Madame Tarlat, pure white, flowers very deep and massive.

which now seem more important, will most surely fade from sight and be forgotten long before Mr. Stiles' work (of which the volumes of *Garden and Forest* are only examples) ceases to have a wide and cogent usefulness. Mr. Stiles was a leader and a teacher in horticulture; he was such by reason of his broad culture, his thorough training, and his lively sympathy with living plants and growing fruits, and all animate nature. There is an unfortunate tendency in certain places in this country, and I suppose in every other country, to measure the value of a horti-

LILY DISEASES.

Lily diseases are often quite troublesome in nurseries, gardens, and greenhouses in this country. Certain fungi (among which certain *Botrytis* are conspicuous) attack many species, and often make very serious work of it. The common Meadow Lily, *L. canadense*, is sometimes found very much disfigured with large dead blotches on the foliage. *L. candidum* is so badly attacked, in this immediate neighbourhood at least, that its garden culture is a business of great uncertainty. The same species often suffers severely

SOIL INOCULATION FOR LEGUMINOUS CROPS.

The cultivation of leguminous crops for the atmospheric nitrogen which they gather and add to the soil, is a subject full of lively interest for all progressive American cultivators. The special use of such crops for soil-cover in orchards has been referred to before. One of the interesting points which investigation has developed is, that most leguminous species are able to forage most successfully for atmospheric nitrogen only when grown on ground previously occupied by the same species. Thus, in some experi-

FIG. 102.—THE UPPER FISH-POND, GATTON PARK. (SEE P. 312.)

icultural leader by the quantity of his so-called "practical experience;" and the application of this very erroneous standard is likely, I fear, to disparage our lamented friend and teacher in the eyes of those very ones who most needed his kind of inspiration. He was a leader by virtue of a much better title than could be given by any number of years' work in hearing Cole's beds or squirting tobacco-juice at noxious little insects. And so it is for the larger qualities of his mind, for all those delicate refinements of taste, and for that something more than academic polish, that we shall feel the vacancy he has left; and it is also for these things that his memory must long be a part of our better ideals.

also in the nursery. The most marked immunity from disease belongs to *L. tigrinum* and *L. Henryi*. Mr. Albert F. Woods, of the United States Department of Agriculture, has been studying the Bermuda Lily disease, which he finds to be due to a combination of causes, acting chiefly, however, by weakening the vegetative vigour of the plant. Improper selection and propagation, mites, fungi and bacteria, all come in for a share of the blame. This suggests that any preventive measures must look to invigorating methods of culture with such treatment as shall keep the plants free from insects and fungi. The use of chemical fertilisers in place of solutions of horse, cow, or sheep manure, is also recommended.

ments made by Mr. J. F. Duggar, in Alabama, Hairy Vetch grown without fertiliser on land where this plant had been repeatedly cultivated, yielded 17,765 lb. of green forage, and 4174 lb. of hay to the acre; while on a field where Hairy Vetch had never been grown, and where the fertilisers applied contained phosphoric acid and potash, but no nitrogen, the yield was only 235 lb. of hay to the acre. On another plot adjoining the latter, and similarly treated, except that the seed was inoculated with soil from an old Vetch field, the yield of hay was 2540 lb., or an increase of 995 per cent. The use of the German preparation, "nitragin," also greatly increased the yield of various leguminous plants. F. A. Waugh

Crocuses, Snowdrops, and Iris reticulata having developed a little activity at the root, will soon show flowers after being introduced to a warmth of 60° by night, and 65° to 70° by day, and will be found of much use where cut bloom is greatly in request. The various bulbs, plunged in coal-ashes and other sorts of protective material, should be examined

every ten days, bringing into the light those which have developed abundance of roots. These include Lilies, Roman and other Hyacinths, Narcissus, Tulips, Frezias, and Lachenalias.

Miscellaneous Subjects.—Roman Hyacinths are pretty flowers for very early flowering, and being very cheap, they should be grown in large numbers by those who need flowers about Christmas and onwards. A good batch, either in boxes for affording cut bloom, or in small pots for other use, may now be placed in the forcing-house, if they were potted and have plenty of roots. Narcissus Paper-white is another useful early bulb that may be put into heat. Those who require early flowers of Lily of the Valley had better rely upon roots that have been kept in cool chambers, such coming into bloom in a fortnight after being placed in heat. The practice of retarding does away with the need of the hard forcing always necessary to get early bloom of freshly-imported crowns. No attempt must, however, be made to retard these once they are taken from the ice, or damping-off will ruin them. On receiving them from the nurseryman, place them in pots or boxes in cocoanut-fibre refuse, and keep them shaded in a warm-house for a few days, afterwards gradually accustom them to the light, but still keeping them in a warmth of 65° to 70°.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leicestershire.

Late Vinerias.—Those Vines on which Grapes are hanging require much attention at this season, or they will lose their plumpness; and ventilation is a very important matter. Let a genial warmth circulate in the heating apparatus, affording free ventilation only when the weather is bright and dry, and very little, and that only by the top ventilators when it is damp. Close the ventilators early in the afternoon, before outer air becomes charged with humidity, and keep a night temperature of 50° to 55°. If the berries shrivel in the least degree it is a sign that the moisture in the borders has given out, and they should be examined, and if really found to be dry, water should be applied on a bright morning, heat being turned on, and all the ventilation possible afforded to dry up the surface moisture before closing time. When the leaves fall, it is better to cut the bunches and bottle them, and in this way afford the Vines a long period of rest, and save the Grapes from loss. Means to shade the bunches of Muscat Grapes must be taken, or they will get browned by the sun, which soon occurs after the foliage has partially fallen and the weather is still sunny. A thin piece of tiffany drawn over the roof on bright days will avert this evil. Before putting Grapes into the Grape-room, let the bottles be cleaned and dried outside, and afterwards refill them with clean rain-water, to which a few pieces of charcoal may be added, or, rather, put the charcoal into the bottles first. Choose a fine day for bottling, and let the bunches be carried so that no shaking takes place, an important matter with Muscat Grapes, as they are easily discoloured. Having arranged the bottles, with the bunches hanging clear of them, keep the room dry, cool, and dark, and twice or thrice a week examine each bunch, cutting out decayed berries. The bunches absorb water freely during the first few days, so that it is necessary to fill up the bottles in three or four days after bottling. If these instructions be carried out the Grapes will remain plump and in good condition till new Grapes are ripe in May.

Early Fig-house.—Where ripe fruit is required in April and May, no time should be lost in getting the early-house started, if that be not already done. If the trees were clean and healthy last season, a copious syringing with soft soap or Gishurst-soap and rain-water after pruning, before the trees are untied, will be all that is needed. The soap may be used at the rate of 8 oz. to the gallon of water. Old ties, shreds, &c., should be burnt if the trees are infested with mealy-bug or scale; they should be similarly treated to Vines as indicated in my last week's calendar. Trees in pots may be plunged in a bed of warm leaves with a temperature of 75°, and doing this will be of great assistance in getting them to make an early start. The night temperature at the start should not exceed 50° at night and 60° by day. Syringe the trees twice or three times a day. Examine the borders where planted-out trees are growing, affording the soil plenty of water if found at all dry at 85°. Later Figs should be kept cool, but not exposed to hard frost, or the points of the shoots will suffer. Resting Figs in borders and pots should be kept on the dry side.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Mushrooms.—Indoor Mushrooms will now be plentiful in most gardens, and be the more appreciated since the supplies from meadowland are exhausted. The gardener should endeavour, so far as his means will allow, to make up fresh beds at fortnightly intervals. Nothing is better for the cultivation of the Mushroom than a dry underground cellar, where the temperature varies but a few degrees at any season. In artificially heated-houses, great care is needful in order not to let the temperature get higher than 60°, or the air becomes parched. The beds should be examined once a week, in order to ascertain if an application of water be needed; the beds often being dust-dry below whilst the surface is moist. Let tepid water then be used, and if the beds have been for some length of time in bearing, one handful of common salt to three or four gallons will be beneficial, or weak manure water may be afforded in place of clear water. Outdoor beds should be matted over, and other covering put over the mats to protect them against frost, snow, and rain. Thatched hurdles answer very well if litter be first placed on the bed.

Chicory, &c.—Where Chicory and Dandelion are used in salads, a good supply of the roots of these plants should be lifted and laid in a frost-proof place in readiness for forcing as may be required. It is a good practice to introduce a batch of roots into heat every week in order to keep up a succession of leaves, as the heads do not remain long in fine condition after they become fit for table. A warm, darkened shed with a warmth of 60°, or the Mushroom-house, will answer for forcing and blanching the heads; or a dozen roots may be put in light mould, in an 11-inch pot, first cutting away the top leaves at 1 inch above the root. Having packed them in the soil with the tops just protruding, afford a good watering, which will be sufficient till the crop of leaves is gathered. Roots once forced are no longer of any use, and should be thrown away.

Celery.—The finishing touches should now be put to the late Celery ridges, and even those already finished may have a little more earth added, or a layer of coal-ashes, as an extra protection against frost. The latter is less liable, owing to its porosity, to cause rotting of the tops. An advantage that the dwarf varieties of Celery, such as Sutton's Al among red, and the incomparable among white ones, is that much less earthing-up is required than is necessary with the tall varieties, which is, of course, a saving of labour, as, after all, 12 inches of nicely-blanched stalk is all that is really necessary, and the long green tops are so much waste.

White Turnips, &c.—These if of full size may now be taken up and stored for use, either putting them in heaps outside, covering with some dry litter, and afterwards banking-up with soil, or into a cool yet frost-proof shed, where they will keep in good condition for many weeks. Such hardy sorts as Chirk Castle, Red Globe, and the yellow-fleshed varieties, are able to withstand the frosts of an ordinary winter, more especially if they are not of full size when cold weather stops their growth. A supply of Jerusalem Artichoke tubers may also be lifted and got under cover, as although these are perfectly hardy, they are difficult to get when the ground is frozen hard, or it lies deep under snow.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

A Suitable Site for an Orchard.—A new orchard should be made, if possible, on land which is fairly sheltered from the north, east, and south-west winds, the soil of which would grow good Wheat, and is heavy rather than light, as well as being either naturally or artificially drained.

Excavating Holes.—For two-year-old trees, the holes in which the trees will be planted may be 18 inches wide and deep, the bottom being broken-up, but left in its place; some of the top spit may then be returned into the hole, and should the staple be impoverished, a small quantity of rotten manure may be mixed with the soil. Let the trees be rather higher in the soil than before; shake in an upright direction when planting, so that the soil may find its way among the roots; fill in about one half, and then make the soil firm by treading it slightly, and fill in the hole, mounding it slightly round the stem. Of course,

before planting any tree, the longest roots should be shortened, and damaged ones cut away. The distance between the trees may range from 15 to 20 feet. Half-standards (that is, trees having clean stems from 3 to 4 feet long) and pyramids are the best forms of trees to grow, and these should be on the paradise-stock. If the soil be wet when the trees arrive, lay them in till it becomes fit to trample upon without injury. In planting, always spread out the roots in every direction; and if the bottom of the hole be a bee-hive-like mound, so much the better. In planting grazing orchards, standards with 6-foot high stems should be employed. If the land be low-lying, the trees should be planted on mounds 12 feet in diameter, and 1 to 1½ foot above the level. All trees should be secured to stakes as soon as planted, doing this loosely, and putting a cushion between stake and tree, in order to prevent injury to the bark. A good watering may be afforded at the roots if the land be dry. The turf in grass-orchards may be returned to the soil provisionally, and in the early spring the holes may be filled in finally, the soil levelled, and the turf replaced and beaten flat. It will be well to place rabbit-proof wire round the trees without loss of time.

Winter-Moth.—As stated in last week's "Calendar" (p. 326), this is the time to take precautionary measures against the Winter-Moth, by placing Horne's grease-bands round the stems of the trees at 3 feet from the ground, more or less according to length of stem; this being the most simple and effective way of preventing the attacks of these pests, by capturing the female-moth, which is obliged to climb the tree to deposit her eggs.

VARIORUM.

JAPANESE MUSHROOMS.—Mr. Robert P. Porter, who has been conducting investigations into the industries of Japan, states that one of the most interesting studies in that country is the growing of Mushrooms in the Shikoku Island, where most of the camphor is produced. This is an important article of export, mostly to China, and during the year 1895, the last year for which the returns are available, the quantity of Mushrooms exported from Japan to all countries amounted to 1,780,597 lb. Of the numerous species of edible Mushrooms, the one called Shitake is the most important, being abundantly exported abroad, and also used for many culinary purposes at home. Logs which are used for cultivating this Mushroom are various species of Oak. The principal districts where this Mushroom is produced are the provinces forming Shikoku, Kiushiu, Wakayama, and Shiozuka prefectures. Oak-trees twenty-five to thirty-three years old are felled in the autumn, and incisions made with axes at intervals of 3 or 4 inches, the incisions generally reaching the woody layer. The trees are then cut into logs of 1 to 5 feet in length, and left in dark, secluded parts of the forest. After the third year, Mushrooms make their appearance in the incised portions. When the growth lessens they are replaced by new logs. The Mushroom grows at each season of the year, winter, spring, summer, and autumn; but the growth in winter and spring is the result of artificial stimulus. The logs are steeped in water for a number of hours, according to the dryness of locality, and then struck with pommels or axes to prepare the beds for facilitating the growth of the Mushrooms. The autumn crop is the most abundant. After being collected, Mushrooms are dried either by the sun or by artificial heat. *Journal of the Society of Arts.*

UNSEASONABLE FLOWERS.—As showing the unusual mildness of the weather generally in this country, a quantity of flowers in great variety and good condition, have been sent us from the gardens of Stokesay Court, Shropshire; amongst them being Tea, H.P., and China Roses, *Crocsmia aurea*, *Tropaeolum penegrinum*, *Kniphofia*, *Malva*, *Sweet William*, *Carnation*, *Mignonette*, *Fuchsia*, *Anemone japonica*, *Sweet Pea*, *French and African Marigold*, *Aster dumosus*, *Pentstemon*, *Tagetes pumila*, and many others which in most cases are usually laid low by the first nip of frost.

THE LINNEAN SOCIETY.—This society held its opening meeting of the session at Burlington House on the 4th inst., Dr. A. GÜNTHER, the president, being in the chair. An interesting collection of zoological and botanical exhibits collected by the Jackson-Harmsworth expedition was shown by Mr. F. G. JACKSON, the leader, and Mr. FISHER, the botanist of the expedition, the former also exhibiting upon a screen a number of photographs of animals and birds which inhabit the Arctic regions. Some lantern-slides of marsh-birds and their nests from photographs recently taken in Spain and Holland were shown by Mr.

had the present shapes and outlines, brilliant colours, the sweet scent and the honey of flowers been gradually developed through the unconscious selection exercised by insects, but this applied even to minor points, such as the arrangement of lines and the different shades of colour. Professor PLATEAU records a series of experiments on the Dahlia, in which he shows that bees come to these flowers even when the ray-florets have been removed; and, discussing this point, Sir J. LUBBOCK said it was somewhat singular that he should have selected as proving that insects are entirely attracted by scent a flower

Professor PLATEAU do not in any way weaken the conclusions which have been drawn by SPRENGEL, DARWIN, and others, and that it is still clear that the colours of flowers do serve to guide insects to the honey, and in this way secure cross-fertilisation. A paper by Mr. W. C. WORSDELL on "Transfusion Tissue" was afterwards read.

— At the evening meeting to be held on Thursday, November 18, at 8 P.M., the papers to be read are:—1, "On Pontobolus Manaarensis," by Prof. A. DENDY, F.L.S., &c.; and 2, "On Haddonella, a new genus of Foraminifera," by F. CHAPMAN, A.L.S., &c.

FIG. 103.—VIEW AT GATTON PARK, SHOWING REIGATE HILLS IN THE BACKGROUND. (SEE P. 342)

REGINALD LODGE. Following the discussion upon these exhibits, Sir John LUBBOCK, M.P., read a paper on "The Attraction of Flowers for Insects," in reply to three Memoirs recently published by Professor PLATEAU. The Professor attempted to show that the colours of flowers do not serve to attract insects; but on the contrary, that this is effected entirely by the sense of smell. Sir JOHN LUBBOCK explained that his view was, like that of SPRENGEL and DARWIN, that we owe to insects the beauty of our gardens and the sweetness of our fields. To them, he said, flowers were entitled for their scent and colour. Not only

which had, so far as we knew, no scent at all [?]. He gave several reasons for disputing the conclusions drawn by Professor PLATEAU from his experiments, and recorded various experiments made by himself to refute them. He had experimented upon species in which the scent is in one part of the flower and the coloured leaves in another, as, for instance, the *Eryngium amethystinum*. The flower is surrounded by brilliant blue bracts, and he found that if the two were separated the bees came much more often to the bracts than they did to the flowers themselves. He maintained, therefore, that the new observations by

THE GHENT QUINQUENNIAL.—*Eheu fugaces!* Next April we shall once more have this imposing ceremonial to record. The covered space allotted to exhibitors covers more than 8000 square metres. Pleasing prospect for the reporters! A special stamp has been prepared, a specimen of which is given in the current number of the *Revue de l'Horticulture Belge*.

DR. HOGG'S LIBRARY.—The total amount realised, remarks "W. R.," by the sale at Messrs. Sotheby, Wilkinson & Hodges, on Thursday last, of

Dr. Hogg's library, was about £372, the number of lots being 232. The following list includes the highest prices:—J. C. Loudon, *Arboretum et Fruticetum Britannicum*, 1838, the numerous plates cleverly coloured by hand, £7 15s.; *The Flower Garden Displayed*, 1732, with many fine coloured plates, very rare, £5 5s.; Leonard Mascall's *The Countryman's Recreation: or, the Art of Planting, Grafting, and Gardening*, 1640, £5 12s. 6d.; Mascall's *Booke of the Art & Maner, howe to Planke & Graffe all sortes of trees, &c.*, by one of the Abbey of S. Vincent in France, with woodcuts, printed by H. Bynnenman, without date, £15; Thomas Hill, *The Profitable Arte of Gardening*, 1593, £7; Dr. R. Hogg, *Hertsfordshire Pomona*, 1878—85, with seventy-six finely coloured plates, £6 17s. 6d.; R. Dodona, *A Nicwe Herball*, 1578, £17 10s.; J. Parkinson, *Paradisi in Sole*, 1620, £10 5s.; and Wylliam Turner, *A New Herball*, 1561, and other works bound up in the same volume £15 15s. All the foregoing were purchased by Mr. Bernard Quaritch.

"BOTANICAL MAGAZINE."—The plants figured in the November number are:—

Mammea americana, Linn.—A West Indian tree, producing a globular fruit of the size of an Orange, the pulp of which has a sweet, slightly aromatic flavour, elsewhere likened to a Turnip. The tree, with its brilliant green leaves and deliciously scented white flower, is so handsome an object that DE TUSSEAC eulogises it as "la Sirène Végétale." There is a tree in the Economic-house at Kew which flowered in 1896; t. 1562.

Tainia penangiana, Hook. fil.—An Orchid having much the appearance of a *Cologyna*, with small fawn-coloured, stellate flowers, with a white lip, the fore-lobe of which is ovate acute, with a central yellow ridge. It was discovered by Mr. CURTIS on damp rocks at Penang; t. 1563.

Cynorchis grandiflora, Ridley.—A native of Madagascar, with long linear-lanceolate green leaves, spotted with brown, as also are the sepals; the flowers are about 1½ inch broad, flat, spreading; petals white; lip violet-purple, with two retuse lateral lobes, and the anterior lobe dividing into two linear spreading sub-divisions; t. 1564.

Drimys Coleae, Baker.—A new species of *Drimys*, found in the Golis range in Somaliland by Miss EDITH COLE, and flowered by her in October last year. It is a bulbous plant, with broad, strap-shaped, fleshy leaves of a pale-green colour, but thickly spotted with darker green spots; flowers each about three-quarters of an inch long, in terminal many-flowered racemes, segments six, linear recurved, whitish, stamens pink; t. 1565.

Scolopus Bigeliorii, Torrey.—See *Gard. Chron.*, 1894, vol. i, p. 267, fig. 8.

BANQUET TO MM. LUBBERS AND DE MIDDELEER.—On November 21 a banquet will be offered to Mr. LUBBERS, the Curator of the Brussels Botanic Garden, on the occasion of his promotion to the grade of Officer of the Order of Leopold. At the same time M. DE MIDDELEER, who has been on the Council of the Linnean Society for upwards of twenty-five years, and President since 1887, is to receive a similar compliment.

MR. DINTER, formerly curator of Commander HANBURY's garden at La Mortola, has transferred his services to Mr. GESSERT at Inachab, near Keetmanshoop, Great Namaland, German South West Africa. Mr. DINTER will be occupied with the afforestation of the district, and proposes to investigate the flora of Southern Great Namaland. He will prepare dried specimens and distribute them in "centuries." The plants will be determined by Professor SCHINS of Zurich. We are glad to say that Mr. DINTER will contribute to our columns notes on the botany of the district, and on the introduction of useful plants into the colony. His first contribution, which is very interesting, will be found on p. 323.

STOCK-TAKING: OCTOBER.—It is not to be supposed that with a trade-war actually raging, and another ready to start, we can look for any improve-

ment in trade—for an increase in the volume or value of either imports or exports. The Board of Trade returns for October place before us a series of facts which it would be well that all parties concerned in the present condition of things should carefully study, and, where possible, promptly end. So far as it goes, our table of extracts from the monthly "summary" speaks for itself—a few statistics added from the mass of figures will assist in better defining the position:—

IMPORTS.	1896.	1897.	Difference.
Total value ...	£9,574,800	£8,043,763	—£1,531,037
(A.) Articles of food and drink—duty free ...	13,630,015	13,031,059	—598,956
(B.) Articles of food and drink—dutiable	3,295,672	3,166,814	—128,858
Raw materials for textile manufactures ...	5,167,994	4,517,491	—650,503
Raw materials for sundry industries and manufactures	4,549,091	5,241,185	+692,094
(A.) Miscellaneous articles ...	1,385,403	1,214,130	—171,273
(B.) Parcel Post ..	93,540	81,161	—12,379

The decrease in the values of imported food and drink is in great part due to a fall in prices of cereals, &c., owing to increased supplies—something, perhaps, to a lowering of the demand. But, by the way, the rise in the value of "animals, living, for food" has been increased by £57,653. Of the principal "minus" items in the record before us, we may note the following:—Tobacco, £120,486; chemicals (!), £75,100; raw material for textile manufactures, £650,513; miscellaneous articles, £141,272. In the "plus" column, we note metals, £144,567; oils, £26,575; raw materials for sundry industries and manufactures, £693,094; manufactured articles, £169,549. The total imports for the past ten months foot up £368,786,726, against £355,850,402—a difference of £12,936,324. Our little fruit, &c., table has all its normal interest, though it cannot always be taken as an index to prices, so much depending on the home stock and the condition of imported fruits and vegetables. At present, the market seems to be well supplied all round, and London youngsters revel in all sorts of Nuts, in good foreign Grapes, in Bananas, Pears, and Pomegranates. The figures are as follows:—

IMPORTS.	1896.	1897.	Difference.
Fruits, raw:—			
Applesbush.	1,601,403	457,447	—1,144,956
Cherries"
Plums"	9,242	29,389	+20,147
Pears"	33,255	107,525	+74,270
Grapes"	298,242	360,151	+61,909
Unenumerated"	115,381	119,816	+4,435
Onions"	786,991	710,701	—76,290
Potatoescwt.	25,036	325,253	+200,217
Vegetables, raw, unenumeratedvalue	£77,081	£77,297	£216

In the matter of—

EXPORTS

a downward tendency has, of course, still to be noted. The total for last month was £19,283,052, against £20,683,457—a decrease of £1,400,405. Amongst the "minus" records are yarns and textile fabrics, £859,910; metals and articles manufactured therefrom, except machinery, £285,562; machinery and millwork, £465,041; apparel and articles of personal use, £62,637; other articles, either manufactured or partly manufactured, £256,958—a heavy list. Of the "plus" recorded are the following:—Articles of food and drinks, £51,492; raw material, £164,918; chemical and medical preparations, £37,284; parcel post, £35,382; live-stock, £10,627. We may add that the decrease for the ten months is given at £6,665,029—the figures for 1897 being £195,274,228; for 1896, £201,339,257. Added to the unsatisfactory state of things at home, there is the still unfavourable aspect of affairs abroad,

concerning all of which the reader is doubtless thoroughly well informed; and we can only hope for an improvement in the two months yet to be placed on the year's record.

THE WEATHER AT FROGMORE IN THE MONTH OF OCTOBER LAST.—Mr. O. THOMAS, of the Royal Gardens, Frogmore, contributes the following observations on the weather during the month of October. The month was very mild and most enjoyable, being sunny, warm, and dry, with a total absence of the storms that usually prevail at this season. The mean temperature was higher than usual, and although there occurred frequently slight hoar-frosts, only once was vegetation injured by night frost, viz., on the 6th, when 7° of frost were registered, blackening Dahlias, &c. After the 20th easterly winds prevailed, and dense fog during the last week of the month. The maximum temperature in the sun was 80° on the 1st of the month, and in the shade it was 65° on the 17th. The minimum, 25°, was reached on the 6th. The total rainfall for the month was .91 of an inch, whereas in the same month of 1896 it was 2.22 inches. The average at Windsor being 3.00 inches. The rainfall for the month is the lowest recorded at Frogmore for the last twenty-three years.

A MILD AUTUMN.—At the Exmouth Chrysanthemum show held on October 28 and 29, several collections of vegetables contained good and fresh samples of green Peas, Scarlet Runner Beans, and Tomatoes. A good show was also made of single and Cactus-flowered Dahlias, Sweet Peas, and some other plants. At the Exeter show, held a week later, on November 4 and 5, a good show of these flowers was again made by Mr. W. J. GODFREY, of Exmouth. All were cut from plants growing in the open air, which had not received the least protection.

THE CHISWICK MUSCAT GRAPE.—Should the very interesting Muscat of Alexandria sport, which for the second season has presented itself on a long rod of one of the Vines in the great vinery at Chiswick, eventually prove to be distinct, it should undoubtedly have the appellation which heads this note. A sport in gardens so well known merits complete association with the place of its origin. Last year the bud sporting threw a weak lateral, and but a small bunch. The berries, however, were so fine that special attention was given to the bud this year. The growth last season was too small to furnish eyes. This year the lateral is, oddly, even stouter than are other natural laterals, and there will be no difficulty in securing many good eyes. The leaves, whilst of the Muscat of Alexandria shape, are yet much more deeply serrated. That is a marked feature of the whole of them on the lateral. The bunch this season, though again not large, carried very fine berries, fully double the size of those on the other bunches, and both seasons setting, though not in the least artificially assisted, was of the very best. The berries so closely resemble those of the well known Cannon Hall Muscat in size, form and colour that there is naturally some possibility that the Cannon Hall sport has after many years been repeated here at Chiswick; but whilst that variety is far from being a free setter, the Chiswick sport seems to be a good one. Of course, a better test will be furnished in 1899, by which time it should be possible to have strong fruiting rods in pots, and others planted out in a house, capable of carrying at least a couple of good bunches each. If a Muscat of the fine form of the Cannon Hall, and as easy to grow and set as Black Hamburgh or Alicante could be obtained, without doubt it would be a grand addition to our white Grapes. The big vinery at Chiswick, it should be remembered, is far from being an ideal Muscat-house.

HOME CORRESPONDENCE.

CARNIVOROUS SLUGS.—I notice that Mr. Webster in the *Gardeners' Chronicle* for October 30 says that he has not found them out of the soil. Now my experience is exactly the reverse of his, for I have only found them when they have been

crawling on the gravel-walks, or in the houses. I first saw them in the gardens at Gledstone Hall, Skipton, Yorkshire, about 1870, and there I saw one devouring a worm, and they were fairly plentiful there. I found one here last year in the plant-stove, and afterwards several outside on the walks. *D. R. Dixon, Stourbridge.*

— *Testacella haliotidea* is found in my garden at Bishopsteignton, Devon, generally at a few inches below the surface, but on a few occasions it has been found neatly covered by dead leaves at the edges of beds, &c. I also noticed it in a garden at Plymouth, and I believe this species to be commonly distributed in the south-west of England. I was offered one some years ago by a postman at Marston, near Oxford, who had found it in his garden. Your correspondent, M. Webster, must be mistaken about the *Testacella* swallowing worms. His many-toothed tongue, a lingual ribbon, is frequently set as a microscopic specimen, and a very curious and beautiful object it is. The object of the shell on its tail is said to be to protect the creature from the attack of another of the same species following it down a worm's burrow. *S. H. Boyle.*

— Though we cannot come up to your correspondent, M. Webster, as to numbers, we have a fairly large stock of the worm-eating slug, *Testacella haliotidea*, at Middleton. They, however, certainly do not remain in or under the soil, but can frequently be seen on the gravel walks after a mild damp night; and last week I found a large one in a small puddle of water, into which it had apparently crawled and got drowned. Even in the daytime, in fairly dry weather, we can generally find them by turning up a board or slate that might be lying on the ground, sometimes with their last meal in the shape of a bristling worm hanging out of their mouths. Like your correspondent, I have found gardeners who eyed them very suspiciously; one especially, who destroyed all he could, with the idea that he was sure to be right in killing a slug. *T. Trollope, Middleton Park Gardens, Oxfordshire.*

THE LINDLEY MEDAL.—As public attention has at last been directed to the Lindley Medal, by your paragraph in last week's *Gardeners' Chronicle*, may I be permitted to respectfully state that, I also, was awarded the Lindley Medal for an exhibit of three *Phalenopsis Schilleriana* at the Royal Horticultural Society's meeting at South Kensington, on March 5, 1867; but though thirty years have passed, the medal has never come into my possession. In April, 1867, Mr. G. Eyles wrote me that the medal was awarded to me, and was in course of preparation, and that I might expect it in a fortnight or so; but the fortnight passed, and many, many more, till, in answer to my enquiry, Col. Davenport, in 1874, obligingly replied, "that when the distribution of Lindley Medals took place I should not be overlooked," a promise repeated in August, 1875, but "Hope deferred maketh the heart sick," and I have long given up any hope that may have lingered through many years, that the promises of the society's secretaries will be redeemed. Still, I may be pardoned in desiring to know whether others actually received the medals? Not for its intrinsic value did I covet this prize, but in winning a medal specially given in memory of one of our greatest horticulturists, and bestowed on such rare occasions, there was to me an honourable distinction, which the society, by withholding the medal, has never recognised. *Philip Parkes.* [Our statement last week was inaccurate. Mr. Anderson appears never to have been awarded a medal, whilst Messrs. Veitch, Bull, Parkes, Taplin, Goode, May, Needle, and Denning were each honoured in this way (see *Gardeners' Chronicle*, December 12, 1874). Has it been awarded since? *Ed.*]

KIRKE'S SOIL-TESTER.—This useful implement seems about to have the usual run of most useful inventions. New ideas, discoveries, may sleep for years, or centuries, but no sooner does some one ahead of, or more sensible than his fellows, give to his fellows something new or better, than hosts of discoverers rush to the front to assure us that they knew all about it twenty, thirty, forty, fifty or more years before. Well, what if they did? Who was the better, the richer, or who had the burdens of their labour lightened through their discoveries? You, Mr. Editor, have had several communications to that effect, so have I; the pity of it is that they were not chronicled at the time they were made, and the invention described and exhibited, and advertised. The labour and the worry of these Grapes and other fruits; the capital that

might have been thus saved, who can calculate! to say nothing of the honours that could have been so honourably and nobly won. But the inventors of soil-testers tied their talents so closely up in napkins that none of us heard a whisper of their existence until a few of the merits of Mr. Kirk's border-testers were truly chronicled. Mr. Sorley, of Falkirk, has courteously written to me of his invention, and his mention of it in a local lecture some twenty years ago. He also consulted Mr. Harry Veitch, who gave him the sound advice to protect it and bring it out. However, he tells me he did neither. And since writing to you I have heard that there may have been several others in the field, neither of them from all I have heard being the same as the one described in the *Gardeners' Chronicle*, and seen at work at Alloa and on other Vine-borders. Neither am I aware that Mr. Kirk makes any particular claim to originality. With him the border or soil-tester has been an evolution rather than a sudden inspiration. The origin and progress of such useful inventions interest only a few. Their practical efficiency and every-day usefulness are a boon to all, and I consider credit is due to Mr. Kirk, who has done what in him lay to render his great revealer of soil and border secrets as indispensable in every garden as knives or spades. *D. T. Fish.*

MUSCAT OF ALEXANDRIA.—My attention was called to an article in your paper of Sept. 25, respecting the Muscat of Alexandria Grapes grown in these gardens. Your correspondent credits me with having the finest house of this Grape in England. This encomium I am not vain enough to believe. His meagre hints on my method of cultivation will, I fear, be misleading to many who read them, as he does not correctly describe them. The vineries are lean-to's, of very light construction, with large panes of glass, so that in a hot summer (not in spring) I find it imperative to shade the Vines lightly, that is, I use one or two thicknesses of fishing-net to obviate any danger from the powerful rays of the sun, and not because ventilation is neglected, as that is a point about which I am very particular. *W. Harman, Neesham Paddock Gardens, Lutonworth.*

GARDENERS' SUPPLANTERS.—The rebuke administered by "Overhanded" in last week's *Gardeners' Chronicle*, under the above heading, was not altogether uncalled for. But he should have taken more trouble to differentiate errors against good taste, or even common decency, from downright mean and despicable conduct. The case in particular to which "Overhanded" refers, is scarcely veiled, and it amounts to this, that certain gardeners, upon hearing that another gardener was very dangerously ill, were ill-advised enough to apply to that gardener's employer for the position that it was thought the gardener would not require longer. But fortunately this skilful and respected gentleman has recovered. Now, no gardener is warranted in seeking a situation held by another, until he is certain that such a mistake is not possible; and in the case of a dangerous illness, this can only be known after actual decease. Any direct action previous to this is condemnable. At the same time, there is no indication exhibited in such a case of a desire to supplant a gardener in a position he is known to still require. There is another practice (and we are thankful to say an uncommon one amongst gardeners) of a widely different nature, where a person, by the most despicable means, slyly attempts to oust another person who has no intention or necessity to vacate the position he holds. Had "Overhanded" referred to such an action, he would have been better justified in using the terms "Supplanters," "Jacob's," "Covetousness," &c. *R. P.*

YORKSHIRE APPLES.—I was greatly interested in the note from Mr. Down of Wassand Hall, &c. the above, and the editorial remarks appended thereto, in the *Gardeners' Chronicle* of Nov. 6, p. 331. When we consider the situation of Wassand and its proximity to the sea coast, the results attained must be pronounced as decidedly good. Your correspondent asks for a recommendation of a substitute for Cox's Orange Pippin, as it does not finish its fruits well with him. My own experience of this variety may be of service to him, this experience, I may add, being gained near Hull, on the banks of the Humber at Brough. Grafted on the Crab stock and grown in the rich alluvial deposits of the Humber Basin, Cox's Orange Pippin grew very vigorously, producing such a large amount of gross wood, but very little fruit, these finishing very badly, being principally produced in the centre of the tree, and very few on the outside branches; thus they were deprived of sunshine and air, the two essentials for high colour and good flavour. Grown

side by side with several recognised rampant growers the Orange Pippin proved the worst example in this respect. The trees had received an annual mulching of farmyard manure; this was discontinued, a heavy dressing of lime was substituted, together with severe root-pruning. In after years, the branches were well thinned, and the fruit was greatly improved in quantity and quality. I have no doubt the geological formation has a great influence on this question, as I have seen capital trees of this variety nearer Hull, when we approach the chalk; also from where I now write, on the magnesian limestone. Cox's Orange Pippin gives as good result as do most other varieties under ordinary treatment. There is no novelty about the above; probably your correspondent has already tried it, if so, as a substitute the well-known Ribston Pippin may be recommended along with these others, which, generally speaking, do well in the East Riding of Yorkshire—Gascogne's Scarlet, Gravenstein, and Sturmer Pippin. Ribston Pippin is not always commended for its regularity of cropping, but there is no doubt about its value if it can be induced to flourish. With me this year it has surpassed all others, and the reports from the Midlands point to the same fact. *F. Dixon, Elmcroft Gardens, Ripon.*

— In reply to Mr. Thomas Down, Hull, as to the variety near it in flavour to Cox's Orange Pippin, I advise him to plant Margil, which, although not ripening any earlier, does well on the Paradise stock, and is best as an espalier. As for districts more to the north of the kingdom, earlier-ripening sorts are a clear advantage—I mean Kerry Pippin, a variety ready in September. It is of the richest flavour, and, although small, it is pretty, and is prolific on the Paradise stock. Another very pretty but small variety of delicious flavour is Benoni (American), to eat from the tree in September. Also Lady Sudeley, introduced some twelve years ago by Mr. Bunyard, should be in every garden, ripening its fruit in August and September—juicy and rich, as well as very productive and handsome; it bears on the points of the branches, like Irish Peach, and is best eaten from the tree. Mother (American) is also to be recommended; it has a rich soft flesh, and ripens in October. A bolder variety, and extremely handsome, is Gravenstein, which forms a large pyramid; the fruit is high-flavoured, although sub-acid. The heavy supplies America sends us annually of this originally German variety are surpassed in flavour by the home-grown article, ripening in September and October. The sugary Grand Sultan or Transparent is a pleasing earliest Apple. In conclusion, I will only name Devonshire Quarrenden and Worcester Pearmain, as probably too well known already to require describing and recommending. A little Sussex Apple, Colonel Vaughan, is the prettiest sight to see a crop of on a pyramid, in this respect similar to Worcester Pearmain. *H. H. R., Forest Hill.*

AUTUMN v. SPRING-DIGGING.—Your able and instructive article on "Autumn v. Spring-digging" in the last issue of the *Gardeners' Chronicle*, will doubtless be read with pleasure by many thinking and experienced cultivators of the soil. May be many persons have experienced some corroboration of the soundness of the methods advocated. In reading the article in question, the thought occurred to me that it might be worth my while to mention what was communicated to me only a few weeks ago by a friend in South Norfolk, but in his case it was autumn v. spring-ploughing; but practically, from a cultivator's point of view, it is one and the same thing. When I visited him he was busy drilling Wheat, and our conversation turned on the cultivation of the soil, and agricultural crops and prospects. Eventually he told me of his experience this year of autumn and winter ploughing, and the resulting crops. Neglect of autumn ploughing was a case of necessity with him; so he claimed no credit for the method or the results therefrom. His soil is a sandy loam resting on sand and red gravel. Last autumn two portions of different fields were left unploughed, and subjected to a deal of trampling and carting throughout the winter. A certain amount of annual vegetation had likewise taken possession of the unploughed ground. Early this spring the two fields were ploughed over, and one was at once sown with Barley, and the other planted with Potatoes. During the summer the crops on the spring ploughed portions of the fields, become noticeable, having darker and more vigorous growth, and all through the summer they maintained it, and finally gave a much better yield of grain and tubers than the autumn-ploughed portions. This so favourably im-

pressed him, that immediately after harvest this year, he sowed his stubbles with Vetches and Mustard, "not mixed," and is now feeding them off with sheep, and intends letting the greater portion of it remain unploughed until seed-time next spring, but for the sake of another experiment, he will autumn-plough a small portion to note the results again, and if satisfactory, he says he will give up autumn ploughing for crops that are sown in the spring. What is true on a large scale is equally so of a small area. In gardens where one has a clayey loam to contend with, autumn digging becomes almost a necessity, for it would be nearly impossible to obtain satisfactory seed-beds without the ameliorating influences of winter frosts; but it is not so with sandy soils. If the above facts can be yearly relied on, what a saving of labour could be effected in the cultivation of light soils, besides the retention of so valuable a manure as the element nitrogen, one of the most expensive and least abiding. *J. Easter, Nostell Priory Gardens.*

FLOWERS IN SEASON AT PENZANCE.—Hoping it may interest the readers of your paper, I send a few facts relative to plants in bloom at this season of seasons. First and foremost have been the Chrysanthemum shows at Penzance, Truro, and elsewhere; but going into the first and last nursery in England, at Penzance, I find that Mr. Hedley Fox has still some plants of *Lobelia cardinalis* var. *Queen Victoria*, which are showing splendid blooms; also of *Kniphofia grandis*, *Dahlia*s, and all in vigorous health; and lastly, *Chrysanthemums*. Has our mild and equable climate at Penzance all to do with the happy state of things of our floral friends, to-day? *A. Hemwood Teague, F.L.S.* (Judging from our correspondence, Cornwall has just now no monopoly in this matter. Ed.)

BELGIUM.

SPECIAL EXHIBITION OF CATTLEYA LABIATA AT BRUSSELS.

An exhibition of *Cattleya labiata* (*Warocqueana*) was organised by the Brussels Orchidéenne, and held on November 7, 8, and 9. On this occasion the large hall of L'Horticulture Internationale looked very beautiful with the Orchids, *Chrysanthemums*, *Palms*, *Tree Ferns*, and other foliage-plants, displayed in it. The exhibition, in fact, was in every way successful.

The jury (M. Kegeljan of Namur, President) awarded:—*Objet d'Art*, 1st class, to L'Horticulture Internationale (M.M. Linden). This exhibit occupied a stage 65 feet long, and included some fine species and hybrids, among them good specimens of *Cattleya labiata*, a number of fine varieties, including John Schultz, with a wonderful depth of colouring; *Marmorata*, as curious as it is interesting and beautiful; *Melusine*, of a charming wine-red colour, with a yellow lip; also *C. gigas*, with six fine large flowers, rare at this season; *Oncidium Marshallianum*, with a large cluster of forty flowers, with wide divisions, and of brilliant colouring; *Odontoglossum crispum* in variety, one plant showing an unusual number of spots and markings; another, well-shaped, white, with cream and fawn shadings; *Cypripedium bellatulum* × *Boxalli*, a pretty hybrid; *Oncidium ornithorhynchum album*, always rather rare; *Cattleya maxima*, some varieties very beautiful; *Odontoglossum nubilosum*, with all the parts speckled with little rose-coloured dots; *Oncidium St. Legerianum*, *Cattleya aurea*, with a large flower and well-coloured lip; and *Miltonia Bluntii* *Lubbersiana*, remarkable for size and colouring. There were also numerous *Vanda corulea*; *V. Sanderiana*, an excellent variety; *Cypripedium in-signe* var. *Lucianum*, one of the best of the insigne group known; *C. Lebrunianum*, *Laelio-Cattleya* × *illuminata* (C. Warneri × *Laelia purpurata*), a fine flower in size and colouring; *Cypripedium insignis* *Lindeni*, much admired; and *Sobralia Lindeni* from Peru, now, snow-white, the lip handsomely ornamented with purple radiating stripes. These Orchids were tastefully grouped with *Palms*, *Ferns*, *Maranta*, *Dieffenbachia*, *Phyllotenusium*, *Leea*, *Heliconia*, *Alcornoia*, and *Dracena*, and with flowering *Chrysanthemums*, which produced a curious effect.

One group in the centre of the hall included a fine *Cocos* in the centre, with a base of *Palms*, *Ferns*, *Aspidistra*, and *Dracena*; on this background, the *Cattleyas* and *Chrysanthemums* showed up well.

M.M. Lucien Linden & Co., covered a staged with 300 specimens of *Cattleya labiata*, which secured them an *Objet d'Art*, 2nd class. There were certainly 3000 blooms, many excellent varieties being represented. The Marquis de Wargny, and Mdlle. Trieu de Teridonck, each obtained a 3rd class award for *Cattleya labiata*; a Bronze Medal was awarded to M. Kierstein of Bordeaux, also for specimens of this plant.

A 1st class Diploma of Honour was allotted for an interesting specimen of *Odontoglossum Rossi* var. *De Bosccherianum*, to M. Guill. de Boscchère; the sepals are yellow; the sepals amply spotted on a yellow ground; a very curious variety.

M. Georges Martin, of the Château d'Olivet, obtained a Diploma of Honour with the congratulations of the jury for

a noteworthy exhibit of seedling *Cattleyas* raised by himself. M. Gibex obtained a Diploma of Honour for a hybrid *Cypripedium Argus* × *C. villosum*; and the Marquis d'Applaineourt a Botanical Certificate for a fine group of *Cymbidium* or *Cypripedium elegans*. *Ch. De Boscchère.*

SOCIETIES.

NATIONAL CHRYSANTHEMUM.

November 9, 10, and 11.

(See also p. 346.)

CHRYSANTHEMUM SHOWS at the Royal Aquarium, Westminster, Kingston, Birmingham, and many other places on Tuesday last, coupled with the ordinary fortnightly meeting of the Committees of the Royal Horticultural Society at the Drill Hall, ensured a busy day for horticulturists. We do not remember to have experienced a more busy day for some years past. But we are not all journalists, and probably some gardeners were not at all sorry to be able to visit the annual Exhibition of the National Chrysanthemum Society upon a day when the business of the Royal Horticultural Society Committees compelled them to come to town.

COMPETITION BETWEEN AFFILIATED SOCIETIES.

There were three Societies in contest this year for the honour of obtaining the Challenge Shield in the First Class. It is for an exhibit of forty-eight blooms, in equal numbers of Japanese and incurved varieties. £10 accompanies the Shield, and the other prizes are considerable. One or more members of each competing society may contribute blooms. The laurels on this occasion were taken by the Bromley and District Chrysanthemum Society, and they were won by an exhibit worthy the class. Japanese and incurved were almost equally good. The Sittingbourne and Milton Gardeners' and Amateurs' Association was 2nd, and the Highbridge Horticultural Society 3rd.

OPEN CLASSES.

Thirty-six Incurved blooms distinct.—The Holmes Challenge Cup and 1st prize was won by Mr. W. Mease, gr. to A. Tate, Esq., Downside, Leatherhead. His blooms were—*Back Row*—Duchess of Fife, Violet Foster, J. Agate, Dorothy Foster, Major Bonaffon, Mrs. R. C. Kingston (very good), William Tunnington, Lord Alcester, Lady Isabel, a very large but rather flat bloom; Robert Petfield, C. H. Curtis, capital bloom; and *Ma Perfection*. *Centre Row*—Robert Cannell, Jeanne d'Arc, Globe d'Or, one of the weakest flowers in the stand; Golden Empress, Lord Rosebery, Jno. Lambert, Violet Tomlin, Queen of England, M. P. Martignac, Lucy Kendall, Empress of India, and Jno. Doughty, a bloom with very poor centre. *Front Row*—Princess of Wales, very neat and pretty, Brookleigh Gem, Empress Eugénie, George Haigh, Bonnie Dundee, Noel Pragnell, very fine; Princess Beatrice, Mrs. Hepper, Alfred Siler, Mrs. Heal, C. B. Whitnall, and a very nice bloom of Miss Haggas. Though the two best collections of incurveds required little judging as between one and the other, at the same time the exhibit from Mr. W. Higga, gr. to J. B. HANKEY, Esq., Fetcham Park, Leatherhead, was one deserving of great commendation. He had a good number of fine flowers, of which the following may be mentioned—Duchess of Fife, Major Bonaffon, J. Agate, Chas. Curtis, Empress of India, Prince Alfred, Jeanne d'Arc, Mrs. S. Coleman, and Bonnie Dundee. The better of the other two exhibitors was Mr. H. Butcher, gr. to C. J. Buss, Esq., Lodge House, Smeeth, Ashford, Kent.

Twenty-four Incurved blooms, distinct.—Of four competitors in this class, the 1st prize was won by Mr. F. G. Foster, Brockhampton Nurseries, Havant. Some of the best blooms in this collection were J. Agate, Mrs. R. C. Kingston, *Ma Perfection*, Duchess of Fife, Miss Violet Foster, Mr. J. Kearn, and Major Bonaffon. The 2nd prize was taken by Mr. H. Butcher, gr. to C. J. Buss, Esq., and the 3rd by Mr. C. W. Knowles, gr. to Mrs. C. Egeaton, Solna, Southampton.

Twelve Incurved blooms.—Exhibitors in the preceding class could not enter in this one. There were eight collections staged, and the winner of the 1st prize proved to be Mr. J. W. Barks, gr. to P. RALLI, Esq., Alderbrook, Cranleigh. All of the blooms in this stand were of first-rate merit, being of good size, neat, and well-built blooms; they were *Empress of India*, Lord Wolseley, J. Agate, Golden Empress, Lord Alcester, Princess of Wales, Miss M. A. Haggas, Mrs. R. C. Kingston, Violet Tomlin, Mrs. S. Coleman, Mrs. Heal, and Lucy Kendall. The 2nd prize exhibit contained some large, fine blooms, and some inferior ones. It was staged by Mr. F. King, gr. to Mrs. McIntosh, Havering Park, Romford. The best flower was a very fine one of C. H. Curtis. The 3rd prize was taken by Mr. A. J. Driver, gr. to the Misses DAVIES, Bridgend House, Stonehouse, Gloucestershire.

Six Incurved blooms, one variety.—There were eleven exhibits, and the only varieties staged were C. H. Curtis, Empress of India, and Queen of England. All the prizes were obtained by the variety C. H. Curtis. The best lot were from Mr. W. Teboy, gr. to Mrs. RYCHOFF, Everlands, Sevenoaks, being the best blooms of this variety that we have yet noticed; Mr. F. King, gr. to Mrs. McIntosh, Havering Park, Romford, was 3rd.

Forty-eight Japanese blooms, distinct.—It was an extraordinarily fine collection that obtained the Holmes Memorial Challenge Cup and 1st prize for Mr. W. MEASE in this class. To prevent, we presume, the usual flat appearance of the exhibits, Mr. Mease raised the centre flowers highest, and then gradually fell to either end. *Back row*—Madame Carnot, Etoile de Lyon, Mrs. W. H. Lees, M. de la Rochetiers, Baron Ad. Rothschild, a bloom of pleasing distinctness to all of the others in the exhibit; J. Brooker, Mrs. C. H. Payne, Vivand Morel (very large), Mons. Paskoucke, Eva Knowles, Pride of Exmouth, A. H. Wood, the sport from Primrose League; Lady Hanham, the new and charming sport from Vivand Morel; Simplicity, Australia, and a Premier bloom of the yellow sport from Madame Carnot. *Centre row*—Lady Ridgway, Mons. Hoste, Edith Tabor, Mons. Grays, Mrs. J. Lewis, E. Molyneux, very fine in colour; Australian Gold, M. Chenon de Leché, Mrs. Chas. Blick, Chas. Davis, Mdlle. M. Hoste, Mrs. G. Carpenter, Mutual Friend, Julie Scaramanga, Mrs. Dewar, and Phoebe. *Front row*—Mrs. Weeks, a beautiful flower when done well; Mons. C. Moll, Col. Chase, Sunstone, Mdlle. M. A. de Galbert, Modestum, Madame M. Ricoud, Baron Tait, Niveum, Mrs. Brims Ironside, Madame Gustave Henri, N. C. S. Jubilee, Miss E. Teichmann, Robt. Powell, Robt. Owen, Viscountess Hambleton. This excellent collection was followed in the prize list by one from Mr. H. Perkins, gr. to the Hon. P. W. D. SMITH, M.P., Greenlands, Henley-on-Thames. Mr. Perkins' flowers were of less size, and generally they were very equal in point of merit with each other. Australian Gold, Edith Tabor and a few others were, however, the best. For 3rd place, P. WATERER, Esq., Fawkham, Kent, just beat Mr. J. F. McLEOD, Dover House Gardens, Rochester.

Thirty-six blooms of White, Yellow, and Crimson Japanese.—These blooms were to be shown in twelve varieties, three blooms of each, on ordinary show boards, and six inches of clear stem to be above the boards. Chrysanthemum foliage of any variety might be shown as a separate stem attached to each bloom. The contest lay between Mr. N. DAVIS, and Mr. W. G. GODFREY, Exmouth Nurseries, Devon, and the advantage lay with the first-named. Each collection presented a commendable appearance, and should encourage the Society to again solicit this and similar less common methods of displaying the blooms. Mr. DAVIS alternated his tints thus, White, Crimson, Yellow, throughout the length of the board. His varieties were, Whites, Madame Carnot, Mr. Weeks, Mdlle. Thérèse Rey, Western King, Crimsoms, Beauty of Castlewood, Dorothy Shea, R. Dean, and Jno. Neville, Yellows, Phoebe, A. H. Wood, Edith Tabor, and Modestum; all of the flowers shown were fine, those of Western King being particularly so. Mr. GODFREY had all his blooms of one colour together, an arrangement we should be sorry to condemn, because the differences in the similarly coloured varieties are by this method the better demonstrated. The 1st prize of £1 was accompanied with a handsome Memorial Challenge Cup, presented by the Trustees of the Turner Memorial Fund.

Twenty-four Japanese blooms, distinct.—Mr. W. Mease, gr. to C. H. BERNERS, Esq., Woolverstone Park, Ipswich, beat five other exhibitors in this class, with a most praiseworthy lot of blooms, good in size, colour, and finish. To specify a few of the best we may mention Madame Carnot, Etoile de Lyon, Edith Tabor, Australia, Modestum, Mdlle. Ad. Moulin, Phoebe, capital in colour; C. Davis, Rose Wynn, and M. Chenon de Leché. It was a collection of blooms of very fine merit also that won 2nd prize for Mr. B. Kenyon, gr. to A. F. HILLS, Esq., Monkham, Woodford Green, Essex, very even in size and merit, the varieties staged call for no special mention. Mr. H. BURCHER was 3rd.

Twelve Japanese blooms, distinct.—This class accounted for a prodigious lot of first-class blooms; there were upwards of twenty collections staged in competition, and we should suppose the judging of such a class was not an easy matter. However, it had to be done, and eventually a collection of blooms from Mr. W. MESENGER was placed 1st. His blooms were Madame Carnot, E. Molyneux, Modestum, Australia, Madame G. Henry, Internationale, Australian Gold, Mrs. C. H. Payne, Phoebe, Miss E. Teichmann, M. E. André, and Edith Tabor. The blooms were all good, and that of Internationale was very fine in point of colour, as was E. Molyneux. The 2nd prize was obtained by Mr. H. SHOESMITH, Clarence Nurseries, Woking, for a very remarkable lot of blooms that lacked coloured varieties, there being too many whites and yellows; had it not been for this the collection would have been very hard to excel. The 3rd prize went to Mr. B. Kenyon, gr. to A. F. HILLS, Esq.

Six Japanese blooms, any colour except white.—There was much competition in this class, and the 1st prize was awarded to six excellent specimens of Phoebe, shown by Mr. J. McKenzie, gr. to F. S. CORNWALLIS, Esq., Little Maldstone; 2nd, Mr. T. H. Lodge, gr. to Mrs. M. H. Hockerill, Bishop's Stortford, for six blooms of Edith Tabor.

Six Japanese blooms, hairy-petalled varieties, distinct.—Mr. Jno. Justice, gr. to Sir R. TEMPLE, The Nash, Kempsey, was 1st, and showed the well-known Hairy Wonder and Mrs. De Ward; also Mrs. W. J. Godfrey and White Swan, both white flowers; Princess Ena, mauve-coloured, very good; and Vancouver, pink, but not very hirsute. The 2nd prize went to Mr. W. Batchelor, gr. to C. BILLYARD TRANK, Esq., Hatfield Park, Uxbridge.

Six Japanese Blooms, one variety, white.—The best bloom in this class were those of Madame Carnot, six very fine specimens of which were shown by Mr. NORMAN DAVIS. There were eight other collections, and with the variety Mrs. Chas. Blick, the 2nd prize was won by Mr. T. H. Lodge, gr. to Mrs. MESEY, Bishops Stortford. The variety Mdlle. M. A. de Galbert, obtained the 3rd place.

Six Japanese Incurred Blooms, distinct.—There was not so much competition in this class as might have been expected. The 1st prize was won by Mr. W. ROBINSON, who showed Oceana, Australia, Western King, Duke of Wellington, Pride of Madford, and Lady Ridgway.

Twelve large flowered Reflexed blooms.—These varieties rarely find many exhibitors in these days. On the occasion under notice there were two in this class, and the 1st prize was taken by Mr. W. ROBINSON, gr. to the Right Hon. Lord LUDLOW, Heywood, Westbury, Wilts. There appeared to be nothing new in the varieties staged, and the 2nd prize was awarded to the other exhibitor, Mr. G. W. FORBES, gr. to Madame NICOLA, Itenge House, Surbiton.

Twenty-four large-flowered Anemone blooms distinct.—There were six contributors in this class, and the best proved to be Mr. JNO. JUSTICE, gr. to the Right Hon. Sir R. TEMPLE, Bart., The Nash, Kempsey. His varieties were W. W. Astor, Madame Lawton, Caledonia, Rouche Lyonnaise, Jno. Bunyan, Mdlle. Cabrol, Mr. H. Gardner, and Sir W. Raleigh.—Robin Adair, Queen Elizabeth, Enterprise, Dame Blanche, Nelson, Owen's Perfection, Delaware.—Junon, Mrs. J. Benedict, Gladys Spaulding, Lady Margaret, La Denil, Fleur de Marie, Miss A. Lowe, and Empress. This stand presented a very pretty show, and most of the flowers were well staged. The 2nd prize was taken by Mr. W. Skoggs, gr. to A. MOSZLEY, Esq., West Lodge, Barnet; and the 3rd by Mr. A. IVEY, gr. to E. C. JONES, Esq., Hadley Lodge, Barnet.

Twelve large Anemone blooms, Japanese excluded.—There were again six competitors, and the 1st prize was won by Mr. J. JUSTICE with an elegant collection of blooms, including Junon, Delaware, Gladys Spaulding, Mdlle. N. Brum, Mrs. J. Benedict, Acquisition, Miss A. Lowe, Lady Margaret, M. C. Lebosqui, Cincinnati, Fleur de Marie, and Gluck. The 2nd and 3rd prizes were taken by Mr. A. IVEY, and Mr. W. RING, gr. to JAS. WARREN, Esq., Caple House, Waltham Cross.

Twelve Japanese Anemone blooms, distinct.—Mr. JUSTICE again took premier honours with good blooms of Mrs. Hugh Girdner, Sir W. Raleigh, Robin Adair, Mdlle. Cabrol, Queen Elizabeth, Nelson, Caledonia, Rouche Lyonnaise, Owen's Perfection, Jno. Bunyan, W. W. Astor, and Enterprise. Mr. W. SKOGGS was 2nd, and Mr. RING 3rd.

Twelve Pompons, distinct.—The Pompons are usually shown in sprays of three, with foliage attached. There were three exhibitors in this class, and Mr. T. CARYER, gr. to A. G. MEISSNER, Esq., Aldenholme, Weybridge, was adjudged best of these. He staged the following varieties: Rubro-perfectum, Prince of Orange, W. Westlake, Perle des Beauties, Osiris, Mr. Holmes, Mdlle. Marthe, President, Mdlle. E. Dorian, La Vogue, Pygmalion, and Toussaint Maricot. It was a first-rate collection of well-grown blooms, and the 2nd exhibit was little inferior. It came from Mr. W. ALDRIDGE, gr. to G. LUCY, Esq., Springfield House, Palmer's Green.

Single flowers.—There were five contestants in the class for twelve sprays of single flowers, three blooms to each spray. These flowers made a glorious display and are worth much more attention than is given them. The best came from Mr. W. ALDRIDGE, gr. to G. LUCY, Esq., who had very fine ones indeed. The varieties were Lady Churchill, Ewan Cameron, Springfield Beauty, Orange Beauty, Purity, Miss Brown, Miss May Braithwaite, Miss A. Munford, Rose Pink, Lizzie Mainwaring, Kate Williams, and Rev. E. W. Remfrey. The whole of these are worth getting by those who do not possess them. The 2nd prize collection was very close to the one just noticed in point of quality, and was staged by Mr. G. W. FORBES. Mr. FIELDGATE, gr. to the Duchess of WELLINGTON, Burihill, 3rd.

TRADE CLASS.

Thirty-six Blooms including twenty-four Japanese and twelve incurred.—The 1st prize was taken by Mr. W. WELLS, Earlswood Nurseries, Redhill, Surrey. In this collection one of the best blooms was Mme. Forlat, a beautiful white or pale lemon incurred bloom of fine size and build: Mrs. J. W. BARKA, a very fine sport from Edith Tabor; G. J. WARREN, Ella Curtis, Lady Hamham, Georgina Pitcher, with others, were interesting and good. The only other exhibit was one from Mr. NORMAN DAVIS, Framfield Nurseries, Sussex; President Nonin, Framfield Gem, and a few other novelties were staged in this collection.

PLANTS.

The best group of Chrysanthemums in pots mingled with foliage plants, and arranged for effect in a circle of 12 ft. in diameter, was adjudged to be one shown by Mr. J. SPINK, Summit Road Nursery, Walthamstow. It was a perfect sugar loaf in shape, and at the summit was a plant of Kentia Forsteriana. The plants were well grown, the blooms large, and there was little fault in the disposition of the plants, except in so much as the method is not the best. The 2nd prize was taken by Mr. W. HOWE, gr. to H. TATE, Esq., Park Hill, Streatham, and the 3rd to Mr. ED. DOVE, gr. to H. E. FAR, Esq., Bickley Hall, Kent.

Trained specimens.—The 1st prize exhibit in the class for six trained specimens of large flowered varieties was down-right excellent. The varieties were Florence Percy, John Shrimpton, John Lightfoot, Col. Smith, Glorioso, and W. Tricker. Those of Col. Smith, Jno. Lightfoot and Jno. Shrimpton were the best.

The best collection of four trained plants was from Mr. F. GILKS, gr. to A. MORRIS, Esq., Court Green, Streatham Hill. The varieties were Emily Silsbury, Col. W. Smith, Vivand Morel, and Mrs. E. S. Trafford. Mr. W. DAVEY, gr. to C. C. PAINE, Esq., was 2nd.

The best six standard trained Chrysanthemums were from Mr. D. DONALD. He had Eva Knowles, Cleopatra, Col. Smith, Chinaman, W. Tricker, and Miss Alice Luckman.

The best standard trained plants in a collection of four were from Mr. W. DAVEY, gr. to C. C. PAINE, Esq., Hildfield, Haverstock Hill, N.W., and he showed Col. Smith, Stanstead Surprise, Cleopatra, and W. Tricker.

The best six trained Pompon plants were also from Mr. D. DONALD, who had Black Douglas, W. Westlake, Scur Melanie, Yellow Martha, W. Kennedy, and Antonius. All of these were first rate.

The best specimen Chrysanthemum plant, any type, pyramidal trained, was a fine plant of Col. W. Smith, shown by D. DONALD, gr. to J. G. BARCLAY, Esq., Knoll Green, Leyton.

AMATEURS.

CUT BLOOMS.—DIVISION I.

Twenty-four Japanese, distinct.—Only two collections were staged, and the better one was from Mr. L. GOOCH, gr. to J. WICKHAM JONES, Esq., Troceter Lodge, South Norwood. The varieties Miss Dorothy Shea, M. Chenon de Leché, and Matthew Hodgson were best shown; Mr. JAS. STREDWICK was 2nd.

Eighteen Incurred, distinct.—Of three collections, that from Mr. C. E. WILKINS, Wellington, Swanley Junction, was best, but the quality throughout the class was not remarkable; Bonnie Dundee and Princess of Wales were the best blooms in the 1st prize exhibit.

Twelve Japanese blooms, distinct.—This class was the subject of a keen competition, and a very commendable lot from Mr. JAS. STREDWICK took 1st prize. In this stand the varieties T. Wilkins, Eva Knowles, A. H. Wood, Madame Carnot, and Phoebe were the best. The 2nd prize went to Mr. J. ACOCK, gr. to Mrs. BACON, Stoneleigh, Sutton, also a very good exhibit.

Six Japanese blooms, distinct.—Mr. W. PERRIN, gr. to C. W. RICHARDSON, Esq., Sawbridgworth, Herts, was 1st, who had really fine blooms of Madame Carnot, G. C. Schwabe, Madame Gustave Henry, Australia, G. J. Warren, and Etoile de Lyon; 2nd, Mr. JAS. STREDWICK. The best six blooms of Japanese one variety were some good specimens of Phoebe shown by ED. SMITH, Esq., Ingleside, Chatham; and with Vivand Morel, Mr. J. STREDWICK, Silver Hill, St. Leonards, was 2nd.

Twelve Incurred blooms, distinct.—Of four exhibitors the best was Mr. C. E. WILKINS, who had a very even lot of blooms of medium size and finish. Mr. WILKINS also won in the class for six blooms. The 2nd prize for twelve went to Mr. C. GODDARD, gr. to W. H. FRANCIS, Esq., Broomfield, Sutton.

Six Incurred blooms one variety.—The 1st prize was awarded to the variety Mrs. R. C. KINGSTON, shown by Mr. WILKINS.

DIVISION II.

Eighteen Japanese, distinct.—Mr. HENRY LOVE, 1, Melville Terrace, Sandown, Isle of Wight, had a stand of very good blooms, including some varieties not frequently staged in exhibition. Mr. J. LOVE was the only other exhibitor.

Twelve Japanese Blooms.—Mr. HENRY LOVE again led here followed by Mr. A. R. KNIGHT, 63, Hardinge Road, Ashford, Kent.

Six Japanese Blooms, distinct.—Mr. H. A. NEEDS showed well in this class, staging the following varieties: Chas. Davis, Miss Elsie Telchmann, Edith Tabor, Madam Carnot, Phoebe, and M. Chenon de Leché. 2nd, Mr. W. E. REEVE, Lyndhurst, Maybury Road, Woking.

The best six blooms of Japanese of one variety was an exhibit of Mdlle. Th. Rey, from Mr. W. E. REEVE, Lyndhurst, Maybury Road, Woking.

Incurred Blooms.—The class for twelve blooms distinct was won by Mr. A. R. KNIGHT, who included a nice specimen of Mrs. R. C. KINGSTON.

MAIDEN GROWERS.

There were a few classes for subscribers who have never won a prize previously at the National Chrysanthemum Society's Shows. For six Japanese blooms distinct, Mr. R. CHAMBERLAIN won 1st prize; and for three blooms distinct the 1st prize was taken by W. T. NEAL, Esq., Chessalon, Woking. Mr. S. ELY, gr. to H. H. GARDNER, Esq., had the best three bunches of Pompons.

SPECIAL PRIZES.

For the special prizes offered by Mr. H. J. JONES for six vases of Japanese Chrysanthemum blooms with twelve inches of stems above the buds, Mr. T. H. LODGE was the best exhibitor, showing varieties with stiff stems that needed no supports.

The class for which special prizes were offered by P. WATERER, Esq., for a specimen Chrysanthemum plant grafted with not fewer than three varieties, was won by Mr. D. DONALD, who had a plant bearing the following varieties: John Lightfoot, Chas. Davis, and Vivand Morel. Another exhibitor had a plant with four varieties engrafted, but exhibiting less good culture.

The special prize offered by Mr. J. T. SIMPSON, for the premier bloom of Japanese Chrysanthemum selected from the entire exhibition, was won by a magnificent bloom of Yellow Madams Carnot in the winning stand of 48 Japanese blooms, shown by Mr. MEASE.

The prizes offered by Mr. W. Wells for six sprays of single flowered Chrysanthemums did not bring such satisfactory exhibits as they should have done.

TABLE DECORATIONS, BOUQUETS, ETC.

The best exhibit in an open class for a table of Bouquet Wreaths, &c., was won by Miss NELLIE EBLEBACH, Stoke Newington, followed by Messrs. HARWOOD BROS., Balham.

There was extraordinary competition in a class for three Espergues of Chrysanthemum blooms, suitable for table

decoration, there being about fifteen exhibits staged. Of these a trio from Mr. D. B. CRANE, 4, Woodview Terrace, Archway Road, Highgate, were adjudged the best; and Miss C. B. COLS, The Vineyards, Feltham, also showed admirably.

The best two vases of Chrysanthemums were shown by Mr. MARK WEBSTER, gr. to E. J. PRESTON, Esq., Kekey Park, Beckenham. Mr. MARK WEBSTER had also the best pair of hand bouquets or posies of Chrysanthemums.

The 1st prize for a hand-basket of Chrysanthemums in a class limited to ladies was won by Miss EASTERBROOK, Fawkham, Kent, from more than half a dozen competitors. The blooms used were exclusively of a variety that reminded us of Princess Clothilda, with a few Asparagus spray. Mr. J. BROOKE, gr. to W. J. NEWMAN, Esq., Totteridge Park, Herts, had the best vase of six blooms of Japanese Chrysanthemums, showing Madame Carnot.

The remaining class in this section was for a hand-basket of natural autumn foliage and berries, and a very pretty arrangement obtained the 1st prize for Miss E. WADSWORTH, Brook House, Basingstoke.

FRUIT AND VEGETABLES.

Although the Society has no titular connection with fruit or vegetables, there is generally some very good produce exhibited at the November show. One of the Special prizes this year was for a collection of Apples, to consist partly of varieties in cultivation on previous to 1837, and of others introduced during the past thirty years. The 1st prize was won by Mr. McKENZIE, gr. to F. B. CORNWALLIS, Esq., Linton Park, Maidstone. The best exhibitors of Grapes were Mr. W. HOWE, gr. to H. TATE, Esq., Park Hill, Streatham; Mr. W. GOULDER, Frome, Somerset; and Mr. W. TIDY, gr. to H. D'ARCY, Esq., Stanmore Hall, N.W.

Mr. A. J. THOMAS, Burgess Hill, Rodmersham, and Mr. G. Goldsmith, gr. to Sir E. G. LODGE, Bt., Leonardslee, were successful exhibitors of Pears and Apples.

Potatoes were shown well by Mr. SILAS COLE, gr. to EARL SPENCER, Althorp Park, Northampton; and Mr. E. BECKETT, gr. to Lord ALDSHAM, Aldenham House, Elstree, had 1st prize for a fine collection of vegetables.

Messrs. Sutton & Sons, Webb & Sons, and Mr. Dorrill and others offered special prizes for vegetables.

NON-COMPETITIVE EXHIBITS.

Messrs. B. S. WILLIAMS & SON, Upper Holloway, staged a pretty group of stove plants, including a fine lot of Orchids in flower, and also well-flowered plants of Begonia Gloire de Lorraine, and several species of Erica. Some of the Crotons were very fine.

Messrs. JNO. LAING & SONS, Forest Hill Nurseries, London, S.E., had a collection of Apples and Pears, and a few plants of Bouvardias, Begonias, &c., in flower.

Mr. H. J. JONES, Ryecroft Nursery, Hither Green, Lewisham, furnished one of the cross tables with fine Chrysanthemum blooms, plentifully relieved with Ferns and pretty foliage plants. Many novelties and some seedlings were shown, the best of which are noticed on p. 340. Also a pretty group of Chrysanthemums in pots, staged in tasteful manner under the large organ; and adjoining this was a record stand of Chrysanthemum blooms from Mr. NORMAN DAVIS, Framfield Nurseries. Western King was capitally shown in about a dozen blooms in this exhibit, and there were extra large blooms of Madame Carnot and many novelties.

Another table was occupied by an exhibit from Mr. THOS. S. WARE, Hale Farm Nurseries, Tottenham, which consisted of Chrysanthemum blooms and Ferns. Some Chrysanthemum blooms and winter-flowering Carnations came from Mr. E. G. RAID, nurseryman, Beckenham Hill.

Messrs. SUTTON & SONS, Reading, exhibited heaps of fine Potato tubers of varieties which the firm believe to be best adapted to resist diseases. Nearly forty distinct varieties were shown, including Sutton's Seedling, Windsor Castle, Nonsuch, Satisfaction, Reliance, and others equally good. The tubers were of the best appearance possible.

A nice collection of Apples and a few Pears were noticed from Messrs. S. SPOONER & SONS, Hounslow Nurseries; and a collection of hardy fruits, Violets, &c., from Messrs. W. & J. BROWN, Stamford, Peterborough and Grantham.

Mr. H. DEVERILL, of Banbury, exhibited some of his remarkable Onions; also Leeks, Celery, Parsnips, Carrots, and other vegetables. Mr. H. BERWICK, Sidmouth Nurseries, Devon, exhibited some very highly coloured Apples and a few Pears.

Messrs. H. CANNELL & SONS, Swanley, Kent, made an exhibit of sprays of Zonal Pelargoniums as bright and charming as ever, always very attractive when the fog days have commenced. They had also a rare lot of Chrysanthemum blooms tastefully set up over a groundwork of Ferns. Amongst these were many novelties, including some of the Continental sorts. The new green flowered Japanese, Madame Edmund Rogers, was represented by three good specimens. A bank of Cannas in many varieties completed the exhibit.

Mr. W. WELLS, Earlswood Nurseries, Redhill, Surrey, had a most commendable group of Chrysanthemum plants in flower, remarkable for the size and freshness of the blooms. This was one of the finest exhibits on the ground floor, and displayed a considerable number of novelties, which have been noticed on p. 340.

Mr. B. LADHAMS, Shirley Nurseries, Southampton, showed a fine lot of blooms of a new decorative Chrysanthemum named Gold Elsie; also Gaillardia blooms, and a few other hardy flowers.

Mr. ROBT. OWEN'S Chrysanthemum flowers from Maldenhead furnished a good-sized table, and many novelties were well shown in this exhibit. Some winter-flowering Carnations in pots from Messrs. CRANE & CLARKE, Hillside Nursery,

March, Cambridgeshire, were scarcely in full flower, but the culture of the plants had been good.

Messrs. W. CUTBUSH & SON, Highgate Nurseries, London, made an extensive exhibit in the gallery composed of Chrysanthemums in pots, also a fine lot of Begonias, Gloire de Lorraine, Ericas, Oranges, &c.

Mr. W. J. GODFREY, Exmouth Nurseries, Devon, displayed a fine lot of Chrysanthemum blooms, each cut with good stout stem, and most of them representative of new varieties, also winter flowering Carnations.

Mr. JNO. RUSSELL, nurseryman, Richmond, had a group of Ivies in pots, exhibiting many diverse varieties. Other stands represented several of the horticultural sundriesmen, various horticultural manures, patent watering-cans, garden labels, &c.

ROYAL HORTICULTURAL.

NOVEMBER 5.—A meeting of the FRUIT AND VEGETABLE COMMITTEE was held on this date at the Royal Horticultural Society's Gardens, CHISWICK.

Present: Mr. H. Balderson, in the chair; the Rev. W. Wilks, Secretary; and Messrs. J. Wright, W. Bates, J. Smith, A. F. Barron, R. Fyfe, W. Farr, and A. Dean.

Four late varieties of Potatoes, tubers of which were seen lifted at a previous meeting, having been cooked, were tasted. Of these Sutton's Supreme and Vert's Diamond Jubilee, both cooking well, but not of high flavour, were awarded two marks. Deficiency in flavour largely characterises modern Potatoes, especially heavy croppers. The best-flavoured variety tasted at Chiswick this season was one sent for trial from the Canary Islands, having much of the Ashleaf character. An extensive collection of Kales, two long rows of each being grown, were next seen. In connection with these, it was noticeable, and the matter merits the fullest scientific enquiry, that all the Breda or Asparagus section, including Ragged Jack, Lapland, and Delaware, in all some ten lots, had almost disappeared, having been eaten up by a fungus [probably a slime-fungus, Ed.] This pest, however, did not affect all the curled Kale section, nor yet the Chou de Milan, or Cottagers' Kale.

The group comprised forty-six stocks, and largely diverse. Of these the following received three marks, or High Commendation: Cutbush's famous strain of tall Scotch Curled, very dark leaved; Brydon's Selected Green Curled (Kent & Brydon), a capital strain of the tall Scotch, but of lighter hue; Dobbie & Co.'s Victoria Kale, a splendid and solid form of the tall Scotch, one of the very best. Jas. Veitch & Son's capital strain of variegated Kale, heads to be seen at the Drill Hall later on. Cottagers' Kale, a good and even stock (C. Turner); Chou de Milan, a first-rate stock of this fine late hard sprouting Kale, from Watkins & Simpson. Culzean Castle, another extra strong-growing stock of the tall curled Scotch (Hurst & Son); and Late Hearting, a dwarf and compact hearting of a semi Savoy type (Hurst & Son). Two Marks, or Commended, were given to Dobbie & Co.; Dwarf Purple Curled, and to Barr's exquisite Purple Curled. These, however, are identical, and are the same as the Purple Arctic or Labrador Kale, well known in commerce.

Three varieties of Beets were seen, but were, whilst clean and even stocks, not of high-class root quality, and inferior to well-known established varieties.

A bed of Parsley also was seen, but the stock was a poor one. A trial of Parsley next year may be worthy consideration.

A large trial of Onions has, so far, been conducted, that several dozen rows of plants, 3 feet apart, are well up; and it is proposed to sow a row of each variety beside these in the spring, and also to transplant one row besides from each autumn-sown variety. A few stocks of Brussels Sprouts were also seen, but they were coarse in growth, and very uneven in quality—much inferior, in fact, to what may be seen in the market-fields. Perhaps the Chiswick soil is too rich and porous; but it is the case that firm, well-trodden soil, not too highly enriched, usually give the cleanest stems, and the best Sprouts.

A trial of Celeries is to be determined at the Drill Hall when blanching is complete, and the winter has tested endurance.

NOVEMBER 9.—GENERAL MEETING.—This meeting, owing partly to the late period of the year, and to the great amount of interest centered in the Show of the National Chrysanthemum Society in a neighbouring building, was a small one, and especially as regarded the number of Orchids and Chrysanthemums staged. The fog and darkness prevailing, made an examination of the various objects very difficult at times.

Floral Committee.

Present: W. Bain, Esq., in the Chair, and Messrs. J. D. Pawle, J. W. Bennett-Poë, C. E. Pearson, J. F. McLeod, J. Jennings, C. J. Salter, J. H. Fitt, Chas. Jeffries, E. Mawley, and R. M. Hogg.

Messrs. HUGH LOW & CO., Bush Hill, Enfield, and Clapton, showed Carnation Mathew's Winter Red, said to be an improvement on the well-known Winter Cheer, in that it is a better winter flowerer; but it is of no use for summer blooming. About fifty plants in 48's were shown. The habit is compact and short, and foliage is freely produced. The flower is of good form, with cupped petals, and the colour a

F. F. THOMPSON, Esq. (gr., Mr. T. Mann), of Pentstemon Seedlings of average merit. CLARKE, March, Cambridgeshire, exhib-

ited a few plants of Tree Carnation Queen Victoria, with flowers of a shade of pink, double, habit of the plant tall, evidently a free bloomer. They also showed plants of the tall-growing white-flowered Bouvardia Humboldtii grandiflora, a striking variety, with large blooms, receiving for this an Award of Merit.

Mr. R. GULZOW, Melbourne Nurseries, Bexley Heath, Kent, showed a group placed on the floor, consisting in the main of varieties of Dracaena, including D. Sanderiana, a magnificent plant, with sixteen stems 6 feet high, and several smaller ones; D. albo-lineata, a narrow-leaved variety, with white and green leaves, and graceful in habit (Award of Merit); D. indivisa Burtons, resembling the type in all respects but colour, which is bronzy-green, with a suspicion of red in it (Award of Merit). The group consisted of the best of modern varieties. Two 6-feet high examples of D. Doucetii, furnished with leaves down to the pots; several Crotons with pendent foliage, a few Palms and Cycads, complete the list of the plants (Silver-gilt Flora Medal).

A group of Chrysanthemums, including Japanese, incurved, single-flowered and reflexed varieties, came from Mr. G. Wythes, gr. to Earl Percy, Stion House, Brentford. Many of the Japanese and incurved flowers were above ordinary form. The group was nicely relieved with Maidenhair Ferns in small pots; and the flowers were placed in two's and three's in bottles, and were mostly fresh-looking specimens (a Silver Banksian Medal).

Mr. JOHN RUSSELL, nurseryman, Richmond, Surrey, placed a group of Tree Ivies of diverse species upon the floor of the Hall, some of the examples reached a height of 5 feet to 7 feet; several of them were loaded with fruits. The silver and the yellow variegated forms were very telling objects. One tall silver variegated example had its stem surrounded with a framework that supported a mass of neatly-trained shoots of the common Ivy, and some others of dwarf stature were similarly treated (Silver Banksian Medal).

Spra of Vitis heterophylla humulifolia in fruit came from A. KINGSMILL, Esq., Harrow Weald. The bunches are short, in some cases very short, and grow axillary on the current year's shoots, and the sky-blue fruits, of the size of Red Currants, are thinly set on the stalks. The leaves are small, with three and five laps. It was grown outside, in front of a glass corridor.

W. W. MANN, Esq., Ravenswood, Bexley (gr., Mr. J. Simond), showed Japanese Chrysanthemum Cyril C. Mann, a white sport from the orange-coloured Col. W. B. Smith. The flower is a creamy-white, an increase of colour being perceptible towards the centre.

Sir TREYOR LAWRENCE, Burford Lodge, Dorking (gr., Mr. Bain), showed Sonerila longifolia Lady Burton, a bronzy leaf densely spotted with white, and patches of the same (Award of Merit). The President of the Society showed an incurved variety of Chrysanthemum named Brunt, of a deep orange colour, a massive flower; also C. Mrs. J. Gardiner, a bright yellow variety belonging to the same section.

Mrs. G. LANE, Highfield, Englefield Green, showed incurved Chrysanthemum, Geo. Lane, a massive bloom (three on the plant) of a pale violet tint.

Messrs. J. VEITCH & SONS, Ltd., Royal Exotic Nursery, King's Road, Chelsea, exhibited Wallflower Parisian Early, a brownish-yellow flowered variety with densely flowered, short, compact spikes; the flowers as large as a florin. The exhibitors received an Award of Merit for the strain. From the same nursery came Aster grandiflorus (Vote of Thanks).

Messrs. W. BALCHIN & SONS, Hassocks Nurseries, Sussex, showed Diplazis glutinosus Jubilee, a bright orange coloured flower, and D. g. rubra, one of a deep orange colour.

Mr. GODFREY, Exmouth, Devon, showed Japanese Chrysanthemum Beauty of Adelaide, a pale lilac variety; also Japanese incurved Mrs. Chas. Keyser, a beautiful bright yellow, of fine form; Japanese Mrs. M. Grant, orange-coloured, with twisted narrow florets; Japanese Mrs. George Gover, reddish lilac, confused, broadish reflexed florets; Japanese Admiral Itto, bright yellow, and stiff, voluted, narrow florets (this got an Award of Merit); Japanese Lady Northcote, white in the centre, florets which acquire a lilac tinge with age; it has much-reflexed narrow florets, of great length. Japanese Wilfred F. Godfrey is a flower that is orange-coloured in the centre, with buff outer florets, incurved, yet with an open centre.

Mr. C. CADDELL, gr., Camfield, Herts, showed Chrysanthemum Lady Ellen Clark, a pyramidal flower, with narrow, open used florets, white.

Chrysanthemums were also shown by Mr. T. GEE, Mr. C. F. THOMPSON, and Mr. OWEN, of Castle Hill Nursery, Maidenhead.

Flowers of Cyrtanthera chrysostephana were exhibited by F. W. MOORE, Esq., Royal Botanic Garden, Glasnevin; the flowers are tubular, of orange and red colour, growing terminally on the shoots—a useful plant at this season of the year.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Sec.), Dr B. Crawshaw, H. J. Chapman, S. Courtault, W. Thompson, J. Jacques, C. Winn, Major Mason, F. J. Thorne, T. W. Bond, W. H. Young, and G. Shorland-Ball.

The Right Hon. Joseph Chamberlain, Highbury, Moor Green, Birmingham (gr., Mr. Smith), sent six grand examples of Cattleyas and Laelia-Cattleyas, prominent among which were Cattleya Folia (labiata ♀, Dowiana aurea ♂). The original was raised by Messrs. James Veitch & Sons, and shown in 1894. The plant now shown had large flowers, the sepals and petals of which were light rose, with a

slight trace of yellow; lip broad, and of rich dark purple colour, with some distinct orange lines at the base (First class Certificate); Cattleya Miss Endicott (maxima × Loddigesii), with very pretty flowers, somewhat resembling those of C. maxima, but of firmer texture. Flowers bright, light rose; lip white, with a tinge of rose, and with distinct purple veining in the centre; Laelia-Cattleya Semiramis (Parrini × Gaskelliana), L.-C. Sallieri (L. purpurata × C. Loddigesii), Cattleya × Massiliensis (Transtr × aurea?), and a very large and finely-coloured Cattleya labiata. The group secured a Silver Banksian Medal.

A Silver Banksian Medal was also awarded to G. SHORLAND-BALL, Esq., Ashford, Wiltshire, Cheshire (gr., Mr. Alex. Hay) for a neat group of excellently grown Orchids, among which were two fine plants of the famous Cypripedium insigne Sanderi, the larger, which seemed to be rather broader and more yellow than the original, though the difference was infinitesimal and such as might occur very readily on growths from the same plant, having six fine flowers (Cultural Commendation). Another fine plant was Cypripedium × Lecanum magnificum, resembling the best form of C. × Lecanum giganteum, but with darker-coloured flowers and shorter flower-stalks (Award of Merit). Mr. BULL also showed a nice plant of the white Dendrobium Phalenopsis album, a good example of Lycaste macrobulba (Maxillaria macrobulba of Botanical Magazine, t. 1228) also known in gardens as L. Youngi; a splendid form of Cypripedium Alfred Hollington, the yellow C. insigne Bullii, and the massive C. i. Harfield Hall variety; C. × Memoria Moensii, C. × Niobe, two fine plants of Masdevallia Veitchiana, &c.

Messrs. JAS. VEITCH & SONS, LTD., Royal Exotic Nursery, King's Road, Chelsea, were awarded a Silver Flora Medal for a group of rare hybrids, among which were Laelia-Cattleya Daphne (L.-C. × Schilleriana (L. elegans alba) ♂, C. Mossii ♀), with flowers equal in size to small C. Mossii; sepals and petals bluish-white, the latter bearing within the margin a pretty veining of purple colour; lip white, with chrome-yellow disc, and purple front; Cypripedium Actem (Lecanum ♀, insigne Sanderi ♂), resembling C. × Lecanum, but of a yellow tint; L.-C. Pallas, L.-C. Lady Rothschild, L.-C. Decia, L.-C. Statteriana, L.-C. Novelty, Cattleya Eurydice (Aeklandia × labiata ♀), C. Portia (Bourgingiana × labiata ♂), Cypripedium Niobe, C. Euryades, C. Tityus, &c.

Messrs. F. SANDER & CO., St. Albans, secured a Silver Banksian Medal for a bright group of varieties of Cattleya labiata, with which were Cypripedium insigne Sanderi, Lycaste Skinneri, the pretty Calanthe × bella, Laelia-Cattleya Broomfieldensis, Laelia autumnalis delicata, Miltonia veillaria Leopoldi, Cattleya aurea, and a finely flowered pan of Sophronitis grandiflora.

Messrs. W. L. LEWIS & CO., Southgate, showed a group of fifty of their fine importation of Laelia pumila, the best of which were L. p. conspicua, L. p. albo-marginata, L. p. grandiflora, and L. p. magnifica. The finest plant in the group was Cattleya labiata Lewisii, with sepals and petals pure white, the front of the lip being soft violet-purple, margined with white (Award of Merit). Also in the group were good Odontoglossum Rossi majus, Momodes pardunum, and its yellow variety, citrinum (unicolor).

Messrs. HUGH LOW & CO., Clapton, staged a group of Vanda corulea, &c., with which were the fine white Calanthe × Veitchii alba (First-class Certificate); the pure white Cypripedium bellatulum album, C. × Lecanum, C. × Niobe, &c.

W. VANNER, Esq., Camden Wood, Chislehurst (gr., Mr. W. H. Robbins), showed a stand of cut Orchids, including Cypripedium insigne Sanderianum, C. Stonii, C. × lo, C. Charlesworthii, C. × Niobe, C. × Harrisianum superbum, C. × Pitcherianum, C. × Schroderae, &c.; also plants of the fine spotted Odontoglossum crispum Dormanianum, Cypripedium × Egermannianum superbum, and C. × Vanneri (superbians × sellig-rum rubrum).

J. T. BENNETT-POE, Esq., Holmewood, Chesham (gr., Mr. Downes), showed Cypripedium × Phoenix, of unknown parentage, with flower somewhat resembling C. × Chas. Canham; also Vanda Sanderiana, Holmewood variety, with flowers nearly circular in form, the segments also being round and good in colour.

C. L. N. INGRAM, Esq., Elstead House, Godalming (gr., Mr. T. W. Bond), showed Cattleya × Comfrey (Lawrencea × Warscewiczii), a neat, light-coloured flower.

HENRY TATE, Esq., Allerton Beaches, Liverpool, sent Cypripedium Allertonense (villosum × bellatulum) and C. insigne bisepalum, a very singular and constant form in which the lower sepals are larger than the upper, and similarly tipped with white.

Mrs. S. WOOD, Moorfield, Glossop, showed Cypripedium × Alcides var. (insigne Maulei × hirsutissimum).

Fruit and Vegetable Committee.

Present: Phillip Crowley, Esq., in the chair; and Messrs. G. Bunyard, G. W. Cummins, A. H. Pearson, A. Dent, W. Iggliden, C. Herrin, F. Q. Lane, J. Smith, Rob. Fyfe, G. Norman, J. Wright, J. Willard, J. Cheal, and J. H. Veitch.

The Apple and Pear flavour competition brought twenty dishes of these fruits of a meritorious description, not a blemished example being remarked among them. The 1st prize for Apples was secured by Mr. TUNTON, gr., Maiden Erlegh, Reading, with Cox's Orange Pippin, fine fruits, above medium size; the 2nd prize was awarded Mr. G. WOODWARD, gr., Barham Court, Maidstone, for Ribston Pippin, the fruit also above average size, and with a very fine appearance.

Messrs. HARTLAND & SON, The Lough Nurseries, Cork,

showed Moreton Pippin, a crimson-skinned fruit of conical form and large size. Several dishes of Ribston and Cox's Orange were shown, also of King of the Pippins, King Henry, Cockle, Fearn, &c., by other persons.

Mr. WOODWARD, of Barham Court Gardens, was 1st for Pears, with Doyenné du Comice; and the Rev. H. GOLDING PALMER, Reading, was 2nd with Glout Moreau, small examples, with unblemished skin. Other varieties shown were Marie Louise, Zepherine Gregoire, Winter Nolis, Emile d'Heyst, Brown Beurré, &c.

From the garden of the Duke of Rutland, Belvoir Castle (gr., Mr. W. H. Divers), came a small collection of Pears (thirty-two dishes), of apparently excellent quality. We remarked of Pears, samples of Beurré du Buisson, Doyenné du Comice, Beurré Jean Van Geert, very high in colour, like Flemish Beauty; Beurré Rance, Marie Louise, Hayshe's Prince Consort, Madame Millet, Easter Beurré, Olivier de Serres, Doyenné d'Alençon, and Beurré Diel (Silver Banksian Medal).

Mr. W. IGGULDEN, Frome, Somersetshire, showed four basketsful of Gros Colman Grapes, 48 lb. in all. The fruit was extremely fine in every point and was awarded a Silver Banksian Medal. It exhibited a good way of showing Grapes in competition or for display in the shops.

Mr. O. THOMAS, of the Royal Gardens, Frogmore, sent a box filled with twenty fine symmetrical fruits of Frogmore All the Year Round Cucumber. The fruits were in all cases 20 inches long, slightly ribbed, short-necked, and without spines. It is a variety that develops fully in the dull season, and was stated to be a cross between Rochford's Market and Dickson's All the Year Round.

Mr. G. WYTHES, Sion House, showed Wythes' St. Martin's Cabbage, a firm-hearted variety.

Messrs. HARRISON & SONS, Market Place, Leicester, showed a very large collection of varieties of Beetroot, and were awarded a Bronze Banksian Medal. It seemed to comprise all the best known varieties of garden Beet.

SOUTHAMPTON CHRYSANTHEMUM.

NOVEMBER 2.—The Victoria Hall was again the site chosen for holding the exhibition of Chrysanthemum.

Groups of Chrysanthemum plants were a distinct feature, so well were they represented. The 1st prize was taken by Mr. C. HOSEY, gr. to J. C. E. D'ESTERRE, Esq., Elmfield Hill, Southampton, with plants less than 3 feet high, thoroughly well clothed with foliage, and carrying fully developed blooms of leading Japanese varieties.

Mr. H. G. HOLLOWAY, gr. to A. BROWN, Esq., Hill Farm Dairy, Southampton, staged the best specimen Chrysanthemum plants, averaging fully 3 feet in diameter, and carrying good blooms.

Cut blooms were thoroughly well shown. In the class for eighteen Japanese distinct there were no fewer than nine competitors. To Messrs. ELCOMBE & SON, Romsey, was adjudged the premier position for excellent examples of leading varieties. Mr. G. NOBBS, gr. to Her Majesty THE QUEEN, Osborne, I.W., was 2nd with a moderately good exhibit.

From Mr. F. G. FOSTER, Brockhampton Nursery, Havant, came the best incurved blooms in the principal class for eighteen varieties; and Mr. J. AGATE, The Nurseries, Havant, was 2nd.

Messrs. ELCOMBE & SON were again successful in the class for twelve Japanese.

Mr. WOODFINE, gr. to Major BOYD, Emsworth, was 1st for twelve incurved varieties.

Vivian Morel was adjudged the premier bloom in the Japanese section, and was staged by Mr. H. M. MONSE, Belmont Nursery, Sholing.

Mr. H. H. LEES was the most successful competitor in the amateur classes.

FRUIT was a feature of the show; excellent were the Grapes staged by Mr. MITCHELL, gr. to J. W. FLEMING, Esq., Chilworth, Romsey.

Mr. G. GOODWIN, Canterbury, contributed the premier Apples in each of the classes set apart for this fruit.

Mr. N. MOLYNEUX, gr. to J. C. GARNIER, Esq., Rookesbury Park, Wickham, Fareham, staged seedling Chrysanthemums of his own raising, to each was awarded a First class Certificate, viz.:—Mary Molyneux, Japanese, a full sized broad petalled, loosely incurving variety of a soft pink colour. Japa ese, Princess Charles of Denmark, bronze-yellow; and to Mrs. N. Molyneux, an immense ivory-white incurved variety.

HEREFORDSHIRE FRUIT AND CHRYSANTHEMUM.

NOVEMBER 2, 3.—This Society held its annual exhibition in the Shire Hall on the above dates. The display of Apples and Pears was, as usual, a very conspicuous feature, and that of Grapes and collections of fruits and vegetables was likewise a very good one; and although competition in the classes devoted to Chrysanthemums was in some cases less keen than usual, the excellence of the flowers was noteworthy.

FRUIT.

Apples, fifty dishes, distinct.—In this class, Mr. BASHAM, Fair Oak Nurseries, Newport, was deservedly placed 1st, with fruits of high quality, and had among his best dishes Mère de Ménage, Bramley's Seedling, Lord Derby, Sandringham, Bismarck, Newton Wonder, Lana's Prince Albert, King of the Pippins, Cox's Orange, and Adams' Pearmain; 2nd, Mr. PITT, Abergavenny.

Apples, thirty dishes distinct.—Here C. LEE CAMPBELL, Esq. (gr., Mr. Bayford), took the lead, with a fine collection, his best being Tyler's Kernel, Gloria Mundi, Winter Nonsuch, Bismarck, Warner's King, Peasgood's Nonsuch, Ribston and King of the Pippins, and American Mother; 2nd, Messrs. PEWTERESS BROTHERS, Pillington.

Pears, twenty-four dishes, distinct.—In this class, Mr. WATKINS, Pomona Farm, Hereford, was 1st, with a fine lot of fruit, his best dishes being Pitmaston Duchess, Beurré Balthé, Doyenné Boussoch, Napoleon, Beurré Diel, and Doyenné du Comice; 2nd, Mr. PITT.

Pears, twelve dishes, distinct.—1st, Lady EMILY FOLEY, Stoke Elith, Hereford (gr., Mr. Ward), having fine fruits of Easter Beurré, Pitmaston Duchess, Doyenné du Comice, Marie Louise, &c.

Apples, twenty-four dishes, twelve culinary and twelve dessert (open only to amateurs in Herefordshire).—1st, Sir J. PULLEY, Lower Eaton (gr., Mr. Williams), with good dishes of Tyler's Kernel, Alexander, Worcester Pearmain, Cox's Orange, King of the Pippins, Blenheim Orange, &c.; 2nd Mr. BLASHILL, Bridge Sollars.

Amongst non-competitive exhibits, Messrs. CRANSTON & CO., King's Acre, Hereford, had seventy dishes of Apples of considerable merit, those noted being Stirling Castle, Beaumann's Red Reinette, King of the Pippins, Grenadier, Schoolmaster, and Golden Noble.

CHRYSANTHEMUMS.

Group of plants 12 feet by 7 feet.—The 1st prize in this class was a Silver Cup, which was won by Mr. Williams, gr. to Sir J. PULLEY, Lower Eaton, with a brightly coloured and nicely arranged group; he was closely followed, however, by Mr. GRINDROD, gr. to P. S. PHILLIPS, Esq., Whitfield; 3rd, Messrs. PEWTERESS BROTHERS.

Cut Blooms.—Thirty-six blooms, twenty-four Japanese, twelve incurved (open).—1st, J. C. HANBURY, Esq., Puntypool Park (gr., Mr. Lockyer), with grand blooms of Amiral Avellan, Chas. Davis, C. Shrimpton, Mutual Friend, Edwin Molyneux, Commandant Blusset, &c. There was only one exhibitor in this class.

Twelve blooms, Japanese (open).—1st, A. S. WRIGHT, Esq., Linton (gr., W. H. Davis), with good flowers of Australian Gold, Commandant Blusset, Aldrick Linden, C. Davies, &c.; 2nd, R. C. B. CAVE, Esq., Colwell (gr., Mr. C. Smith).

Twelve blooms, incurved (open).—1st, J. C. HANBURY, Esq. (gr., Mr. Lockyer), with a finely finished lot, those noted being Charles Curtis, Madame Darier, and Brookleigh Gem; 2nd, A. G. WRIGHT, Esq.

A Gold Medal was offered for eighteen blooms, and was won by Mr. LOCKYER with a good even lot.

In classes open to Herefordshire only, Mr. GRINDROD and Mr. BAYFORD were prominent prize-winners.

WATFORD CHRYSANTHEMUM.

NOVEMBER 2, 3.—The Watford Chrysanthemum Society held their twelfth annual show on the above date, in the Clarendon Hall, Watford. The exhibition was most successful, the entries outnumbering those of last year, whilst the high standard of the exhibits was fully maintained. The groups were well varied in treatment, and the cut blooms were choice, and the exhibits of fruit and vegetables were slightly above the average of former years.

In Division I, open, the prizes for the best miscellaneous groups, and groups of Chrysanthemums, went to Lord ALDENHAM, gr., Mr. Beckett, and Mr. W. K. D'ARCY, the latter exhibitor being the winner of the Silver Cup offered for the best group. For cut blooms the main awards fell to Lord ALDENHAM's gardener, the Rev. H. BURCHELL HERNE, Mr. V. M. MARTIN, Hon. A. HOLLAND HIBBERT, and Mr. T. F. BLACKWELL. In the open classes for bouquets, wreaths, and crosses, the choicely arranged exhibits of Messrs. SCRIVENER & CO. again easily carried off all the 1st prizes, Mr. KETTLE taking three 2nds.

The special prize for the best incurved bloom in the show was carried off by Lord ALDENHAM for a fine large "Charles Curtis," whilst his lordship's "Oceania" captured the special for the best Japanese bloom shown.

Some splendid clusters of Grapes in the miscellaneous class secured premier honours for Mr. W. K. D'ARCY and Hon. A. HOLLAND HIBBERT; similar awards for vegetables and Mushrooms going to Lord ALDENHAM and J. C. JOURDAIN, G.C.M.G., respectively.

In the member's classes, keen competition ruled in the cut bloom classes, and it must suffice if we name the chief prizewinners. These were Mr. T. P. BLACKWELL, Mr. SKILBECK, Mr. A. C. ROWLANDS, and Mrs. PART; whilst the chief winners in the group-classes were Viscount ESKER, Mr. JOURDAIN, Mr. MARTIN, and Mr. H. S. SKERRY. Prizes for table-plants, Primulas and Cyclamens, were gained by Mr. S. T. HOLLAND, Lord ALDENHAM, Mrs. PART, and Mr. BLATHWAYS; and the winners in the fruit and vegetable classes were T. F. HALSEY, M.P., Lord ALDENHAM, Mr. W. F. D. SCHREIBER, Rev. H. F. H. BURCHELL HERNE, Mr. R. HENTY, Mr. KESTISH, Mrs. HUMBERT, and W. JUDGE.

The cottagers' exhibits were numerous and very well arranged.

The division for ladies only included awards for table decorations, which were taken by Miss MEAD and Miss M. D. SMITH, with some tastefully arranged flowers; whilst the same ladies took honours for a single stand of cut flowers. Miss BELGROVE obtained two 1sts for six buttonhole-bouquets (gents), and three buttonholes (ladies); whilst Miss SMITH won the 2nds.

ISLE OF WIGHT.

NOVEMBER 2, 3.—A successful show of Chrysanthemums was held at RYDE on the above dates. On this occasion a successful exhibitor, Mr. T. W. BUTLER, gr. to S. BIRD, Esq., Slatwoods, East Cowes, won the Challenge Cup for the second time, it becoming therefore his property.

The Isle of Wight Chrysanthemum Society held their thirteenth annual exhibition at NEWPORT on Thursday and Friday 4th and 5th inst.

The exhibits were less numerous than last year, but no falling off was observed in their quality. Specimen plants formed a special feature of the show; a plant by Mr. W. SCOTT of Soar Dorothée Seville, being 20 feet in circumference, and possessing upwards of 200 blooms. Mr. J. J. LIMINGTON had a huge plant of W. Tricker, and Mr. E. W. SHEPARD, a magnificent plant of E. S. Trafford.

The SHANKLIN Chrysanthemum Society held its show on Thursday and Friday, November 4 and 5. Here it was noticeable that exhibits were more numerous and of better quality than last year.

Mr. H. LOVE secured the Isle of Wight Horticultural Improvement Association Certificate for Cultural Merit; whilst Mr. M. SILSBURY received the association's Award of Merit for seedling Chrysanthemum blooms of Nina Dabbs.

The monthly meeting of the ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION was held on Saturday, 6th inst., at Newport. Dr. J. GROVES, B.A., J.P., presiding over a large attendance of members; and Mr. J. Barkham gave a discourse on the cultivation of Chrysanthemums by amateurs, dealing lucidly with every stage in the cultivation of the plants. A profitable discussion arose on the Wood Leopard Moth Caterpillar, a member having sent a specimen with the chips worked out of the burrow or tunnel; and on the worm-eating slug Testacella balitoides, a member having observed the habits of this gardener's friend. Several new members were elected.

WOLVERHAMPTON CHRYSANTHEMUM.

NOVEMBER 3.—This exhibition was opened at the Drill Hall, Wolverhampton, on the above date, by the Mayoress of Wolverhampton, a large company being present. The quantity was large, and the quality of the exhibits excellent on this occasion; the Japanese section claiming deservedly the greater amount of attention from the visitors, while fruits and vegetables were numerous and of good quality for the time of year. In the competitive classes, the competition was keen; and among exhibitors of Japanese varieties especially, many fine blooms in fresh condition being exhibited in almost every stand.

Mr. C. T. MANDER, The Mount (gr., Mr. G. F. Simpson), was 1st for a group of Chrysanthemums, in which very fine blooms of Madame Carnot, Sunflower, Edwin Molyneux, Commandant Blusset, J. Agate, C. Curtis, were remarked. The 2nd prize fell to W. F. BAKER, Esq., Avenue House, Tettenhall (gr., S. Whitehouse).

Another kind of group consisted of Chrysanthemum, plants and foliage-plants intermingled, and here Miss PUNT, The Wergs, Wolverhampton (gr., G. Bradely), was the winner, the flowers being pleasingly set off by Eulalia, Bamboos, well-coloured Crotons, &c.; Mr. SANDER, The Terrace, Oaken (gr., G. Minton), was 2nd.

The Earl of HARRINGTON (gr., Mr. Goodacre), was 1st in the twenty-four incurved bloom class, showing extra good flowers of Mrs. R. King, Madame Darier, Lord Alcester, C. H. Curtis, John Doughty, Queen of England, Empress of India, &c. Messrs. J. R. PEARSON & SONS, Chillwell Nurseries, Nottingham, being the 2nd.

In the competition for the best twenty-four Japanese, H. T. HAYHURST, Esq. (gr., W. Bremmell), was 1st; his blooms being Amiral Avellan, Edith Tabor, Commandant Blusset were fine; and Mr. G. PHILLIPS, Shrewsbury, was 2nd.

Among non-competitive exhibitors, W. HAYTON, Esq., Hill Grove, Kidderminster (gr., Mr. T. Pole), staged a number fine bunches of Gros Maroc, Gros Colman, and Muscat of Alexandria Grapes; Messrs. DOBBS & CO., Wolverhampton, ornamental shrubs and a collection of vegetables; Mr. R. LOWE, nurseryman, Wolverhampton, a group of Chrysanthemums, Palms, &c.; Messrs. JONES & SONS, Shrewsbury, bouquets of Cactus Dahlias, and stands of Pompon Dahlias arranged with autumn foliage; Mr. JAMES HUGHES, Tettenhall, of Ferns and Chrysanthemums.

In the class for six table plants, Earl SPENCER, Althorpe, Northampton (gr., Mr. S. Cole), was the most successful exhibitor.

A few Orchids were well shown by Alderman GEO. THOMPSON, Dudley, and F. SANDER, Esq., Oaken.

EALING HORTICULTURAL.

NOVEMBER 3.—The Victoria Hall was well filled on this occasion, handsome groups lining the side walls. The tables running the length of the hall were well filled with fruit and flowers of a high quality; while vegetables were a very meritorious feature, especially from the allotment holders.

The best of the large groups came from Mr. C. Edwards, gr. to H. PEAL, Esq., Ealing, who had well-grown plants and fine heads of bloom; Mr. John Hay, gr. to T. LILLY, Esq.,

A. WARBURTON, Esq., Vine House, Haslingden (Mr. T. Lofthouse, gr.), presented the hybrid Cattleya, The Czar, which resembles C. x Victoria Regina, but is much superior to it, in having very large flowers, with thick segments, and a large lip of good colour (First-class Certificate).

J. LEMANN, Esq., West Bank House, Heaton-Mersey (Mr. Edge, gr.), showed one of the best forms of Vanda coerulea, bearing 40 flowers, of much substance and general merit. It received a First-class Certificate.

The same grower had a fine variety of Cypripedium oeanthum superbum, a finely-grown plant of Cymbidium Traceyanum, which received a Cultural Commendation; and another one, the better of the two as regards condition, which received an Award of Merit. Other good things were presented by Mr. LEMANN.

THOS. STATTEN, Esq., Stand Hall (Mr. R. Johnson, gr.), had a very good lot, the best being a very large plant of Cypripedium Leeanum Albortii, which received an Award of Merit; and the same honour was given to the reverse cross of Cypripedium x Phoebe, a large flower.

O. O. WHOLEY, Esq., Bury (E. Rogers, gr.), showed a large lot of cross-bred Cypripediums, but none of them received a recognition.

E. J. SIDEBOTHAM, Esq. (Mr. Shiner, gr.), had an Award of Merit for a bright flowered Cattleya labiata.

GEORGE ROWE, Esq., Clarence Drive, Timperley, had a good healthy plant of the so-called Cattleya Hardyana, but there have been so many of this plant shown that this one was passed without honours.

An Award of Merit was voted to cut flowers of a good Cattleya Dowianii, but there was a good bit of grumbling over this, seeing that so many of the choicest gems of the Orchid-houses were passed by.

W. GERT, Esq., had Cattleya x Mantini and one or two other plants. Mr. JAMES ANDERSON had a fine, pale variety of Laelia grandis tenebrosa, and several Cattleyas. Mr. DUCKWORTH, of Shaw Hall, Flixton (Mr. H. Twedale, gr.), had a good plant of Cattleya x Masdevallia nobilior. H. WORTHINGTON, Esq., Abbey Lawn, Whalley Range, had the rare Catasetum splendens Worthingtonianum—the best of the family; it received an Award of Merit. Wm. THOMSON, Esq., the chairman, had a nice showy lot of miscellaneous Orchids, which received an unanimous Vote of Thanks. The committee do not sit again till the 25th of the month.

DEVON AND EXETER CHRYSA- THEMUM AND FRUIT.

NOVEMBER 4, 5.—While showing little evidence of advance, the 186th exhibition of the society was moderately satisfactory. The groups were hardly so fine as they have sometimes been, and those classes lacked competition, there being a prize for each entry in the leading classes. In the cut blooms and in the fruit classes the contest was, in many instances, fairly keen.

Groups.—For a group of Chrysanthemums in pots, not fewer than eighteen varieties, arranged in a circle of 10 feet diameter, the 1st prize went to Mr. W. BROOK, Parkerswell (gr., W. Rowland); and a close 2nd to Mr. W. PRIMO, St. David's Hill (gr., H. Stocker). Mr. BOWLAND's group winning through superior finish and arrangement, rather than for quality of bloom. For the first appearance in the show hall, Mr. STOCKER's exhibit was more than creditable.

In a smaller group, another new Chrysanthemum exhibitor came to the front in Lady DUCKWORTH, Knightleys (gr., W. R. Baker).

A 1st prize for a miscellaneous collection of plants, including Chrysanthemums, went to Mr. BROCK, who was an easy 1st.

Cut Blooms.—The Silver Cup for the best collection of thirty-six Japanese, distinct, was keenly contested for, the judges eventually awarding it to Mr. H. HAMMOND SPENCER, Teignmouth (gr., G. Foster); and the 2nd prize to Mr. V. STUCKEY, Langport (gr., Mr. Lloyd). Mr. Foster's blooms showed greater depth and body, but Mr. Lloyd's were fresher, and ran the 1st collection very close indeed. To the winning board was awarded the National Chrysanthemum Society's Certificate. Among the best blooms were Australia, Mr. G. W. Palmer, Viscount Hambleton, Mutual Friend, Mr. H. Payne, and Mons. C. de Leche.

In the class for eighteen Japanese blooms, Mr. HAMMOND SPENCER and Mr. STUCKEY were again 1st and 2nd respectively.

In the six white Japanese, one variety, the Rev. H. HUTCHINS, Teignmouth (gr., F. Hill), was 1st, with M. Carnot.

The 1st prize for the best six blooms of a yellow Japanese went to Mr. H. SPENCER, for very fine blooms of Phoebe.

Single-flowered varieties were few in number, but good, Mr. M. FABRANT winning with a fresh and meritorious lot.

In the Anemone flowered, Mr. W. MACADAM SMITH, Wivelacombe (gr., C. Cooper), was 1st, his Owen's Perfection being very good.

Incurved varieties were not shown numerously or remarkably well.

Fruit.—Grapes were much better than usual, and the classes were well contested. The 1st prize for three bunches any other kind than Black Alicante and Muscat of Alexandria, went to Mr. F. M. CANN (gr., W. Kingdon), who staged excellent bunches of Lady Downes' Seedling.

The 1st prize for three bunches of any variety brought out the old Trebbiano Grape in good form. Mr. V. STUCKEY was 1st.

The premier prize for Black Alicante was won by Mr. G. W. MATTHEW, Exmouth, an amateur who showed very fine fruit.

In Muscat of Alexandria, the Rev. A. H. HAMILTON GELL (gr., Mr. Barnes), was 1st.

In the premier class for Apples in thirty varieties, Sir THOS. D. AGLAND, Bart., was 1st, with a splendid collection.

In the twelve varieties class, Sir DUDLEY DUCKWORTH KING, Bart. (gr., J. McCormack), won premier honours with an excellent lot.

The first for flavour went, as usual, to Cox's Orange Pippin, which was shown by Mr. F. HEARN, Aliphington (gr., F. Anning), the same exhibitor staging one of the finest dishes of Cornish Gilliflower ever seen at this or any other show.

Pears were not good or numerous. The honours in dessert Pears for flavour went, of course, to Doyenné du Comice, which was particularly well shown in several instances.

Trade exhibits included collections from ROBERT VIGNON & SON, Exeter; W. J. GODFREY, Exmouth; W. B. SMALL, Torquay; THE EXETER NURSERY CO., JARMAN & CO., Chard; RUSH & CO., Exeter; C. G. SLATER, Heavitree; BUNYARD & CO., Maldstone; FOOTE & CO., Sherborne.

LEYTON AND DISTRICT CHRYSA- NTHEMUM.

NOVEMBER 4, 5.—This was the first exhibition of a new society whose sphere of operations extends over south Essex; and it must be admitted they started remarkably well, the spacious Town Hall being filled to overflowing with exhibits generally of a high order of merit. The veteran Mr. D. DONALD being the chairman of the committee, refrained from exhibiting; but he placed a group on the platform, flanked on either side by one of his superb specimen plants.

Groups arranged for effect were wonderfully good in that class open to all. Mr. J. SPINK, nurseryman, Walthamstow, staged superbly-grown and flowered specimens on single stems; Mr. C. Bartlett, gr. to Mrs. JONES, Walthamstow, was 2nd. In the class for a group arranged for effect, with foliage, Mr. SPINK was again 1st; and Mr. W. CADZ, Wandstead, 2nd.

In the amateur's division for a group, Mr. W. CASSIDY, Walthamstow, was 1st; and Mr. E. J. PETER, Walthamstow, 2nd.

The three best dwarf-trained specimens were from Mr. G. Whitehouse, gr. to S. NICHOLS, Esq., Whipps Cross, who was also 1st with three standard-trained specimens, finely grown and flowered, the varieties being W. Seward, W. Trioker, and John Shimpson.

Mr. SPINK had the best four bush-trained specimens, all Japanese, admirably grown and flowered; Mr. WHITEHOUSE, a good 2nd.

Cut blooms were remarkably good, especially the twenty-four from Mr. R. Kenyon, gr. to F. HILLS, Esq., Monk-hams, which were very fine throughout in such new varieties as Mrs. C. Bick, Mutual Friend, Phoebe, Lady Hanham, Edith Tabor, Lady Byron, and Australian Gold. A grand bloom of Mons. Pankoucke was very striking. Mr. R. H. BROWN, Walthamstow, had the best twelve varieties, and Mr. W. H. LOCKER the best six of one variety.

Mr. W. J. SIMMONS, Wandstead, had the best twelve incurved, chief among them R. Cannell, Princess of Wales, Major Bonnafton, Mrs. Jas. Murray, C. H. Curtis, &c.; Mr. J. MALLETT was 2nd. Mr. SIMMONS had the best six varieties.

Several classes were set apart for amateurs, Messrs. W. CASSIDY and T. SMITH being the leading winners of prizes in the cut blooms; and there were several classes for table decorations, in which ladies competed. In the open class for a dinner table Mr. L. H. CALCUTT, Stoke Newington, was awarded the 1st prize.

ASCOT AND DISTRICT CHRYSA- NTHEMUM.

NOVEMBER 4, 5.—The above Society held its Chrysanthemum, Fruit and Vegetable Show in the Grand Stand. The open class for twenty-four distinct Japanese blooms brought ten competitors, and there were nine collections staged in the class for twenty-four incurved distinct groups of Chrysanthemums, which were never better. The 1st prize exhibit of Mr. Lane, gr. to Miss DURING SMITH, King's Ride, Ascot, was composed of very dwarf, well-foliated plants, carrying heavy blooms. Messrs. J. LAING & SON, Forest Hill, sent about fifty dishes of superb Apples and Pears. Messrs. ISAAC HOUSE & SONS, Coombe Nurseries, Westbury-on-Trym, Bristol, had a good group of Violets, Princess of Wales, California, &c.

Cut-flowers (Open), twenty-four Japanese, distinct.—T. B. KEYWOOD, Esq. (gr., Mr. C. J. Salter), Woodhatch, Reigate, was a good lot with solid, fresh-coloured blooms; Sir GEORGE RUSSELL, Bart., M.P. (gr., F. Cole), Swallowfield Park, Reading, was a good 2nd.

For twenty-four incurved blooms, distinct, F. W. FLIGHT, Esq., Twyford (gr., W. Neville), was 1st with clean, neat, but rather small and flat flowers; 2nd, T. B. KEYWOOD, Esq., with larger flowers, but less fresh.

For thirty-six blooms, eighteen incurved and eighteen Japanese distinct, confined to the society's district, only two competed, and the Silver Cup was easily won by Mr. W. Lane, gr. to Miss D. SMITH, King's Ride, Ascot. This is the third consecutive time Mr. Lane has taken this Cup, and it now becomes his property.

For twelve incurved blooms distinct, R. C. CHRISTIE, Esq.

(Mr. W. Wilson, gr.) was 1st with nice even blooms, but a close 2nd was Lady ISABELLE BRAVA (Mr. Fred Hereman, gr.), Rose Mount, Bunninghill.

The best twelve Japanese blooms distinct: Mr. W. WILSON was again 1st with grand flowers of Modestum, and Mons. Pankoucke.

There were distinct classes for miscellaneous plants, and for fruits and vegetables.

THE BARDFIELD OR TRUE OXLIPI.—In the last issued number of the *Journal of the Linnean Society*, Mr. MILLER CHRISTY has a valuable paper on the common Primrose, *P. acaulis*; the Cowslip, *P. veris*; and the true Oxlip, *P. elatior*. The common or hybrid Oxlip is a cross between the Cowslip and the Primrose. Mr. CHRISTY sketches the characteristic points of distinction and the geographical distribution of the several species, and especially of the true Oxlip, which is rigidly confined to the boulder-clay, or rather to a restricted portion of that formation. The common Primrose, *P. acaulis*, is absent from the Oxlip area, but the Cowslip, *P. veris*, is abundant in it. Hybrids occur between elatior and acaulis very commonly, especially along the line where the areas of distribution of each species meet. Hybrids between the Cowslip and the true Oxlip are rare.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending November 6, is furnished from the Meteorological Office:—

"The weather during this period continued very dry generally, the only rain experienced having fallen at some of our south-western stations on October 31, and in the east and south-east of England on November 6. Local fogs and mists prevailed during the earlier part of the week, and a good deal of cloud and gloom later on.

"The temperature was rather above the mean almost everywhere, but only just equalled it in 'England, E.' The highest of the maxima were registered during the earlier part of the week, when they varied from 63° in 'England, N.W.' to 62° in several other districts, to 58° in 'Scotland, W.'

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "*Gardeners' Chronicle*" has, since the reduction in the price of the paper, **MORE THAN DOUBLED,** and that it continues to increase weekly.

Advertisers are reminded that the "*Chronicle*" circulates among **COUNTRY GENTLEMEN, and ALL CLASSES OF GARDENERS and GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is** *preserved for reference in all the principal Libraries.*

THE Gardeners' Chronicle.

SATURDAY, NOVEMBER 20, 1897.

A STREATHAM GARDEN.

"THE Rookery" stands upon the brow of Streatham Common, and is the present residence of Lady Key. The house was built long before an ever-expanding London had encroached to Streatham Common, when, indeed, for most practical purposes, the locality had as little pretension to urban life as the New Forest possesses to-day. A water-supply, a railway-station, gas, and other modern necessities did not enter in those days into the everyday life of the Streatham Common district. It seems to be pretty clearly known that the building was erected by a smuggler, who used to convey his ill-gotten goods from the South Coast to cellars he had made below this residence, the transference, of course, being deputed to armed gangs of men. In those days the great North Wood was cropped with forest trees, but it has departed long since, and its only influence that can be observed to-day is in the fact that it succeeded in perpetuating its name in the district by which it was supplanted—Norwood. As one sees the number of omnibuses that arrive at Streatham Common every few minutes from the City, a good many of the historical associations of The Rookery that one learns from Mr. W. G. Turner, who has been gardener at the place for about forty-five years, appear incredible, and would be so had circumstances not afforded us similar experience in other districts that have fallen before the "forward" growth of the metropolis. The present Lady Key has resided here for fifty-six years, and it is of interest to speculate what will become of The Rookery when she ceases to need its tenancy? It may be re-let, and it may not, the probability is that bricks and mortar will invade the grounds; and it is whispered that even now such action has been determined upon.

Before the end comes, these few notes may be interesting, for it is a place where, years ago, gardening was practised successfully, if not extensively; and Mr. Turner has won many prizes for fruit in the old "Regent's Park days," about which the most venerable of present-day gardeners are always eloquent. On reference to fig. 105, p. 359, a partial view of the front of the house may be seen. It is beautifully covered with Magnolias, Myrtles, and Ampelopsis. At the end may be noticed a fine Cedar of Lebanon, not aged, but of excellent proportions. There are two other good specimens of the same species in front of the house, and a poor tree of Araucaria imbricata. Concerning this species, Mr. Turner says: "I bought it about thirty years ago from Mr. Jno. Waterer, and it was then 10 to 12 feet high. It grew splendidly, and every two or three years I removed a larger circle of the clay soil from around the roots,

and gave it a more agreeable compost. But at last it failed to grow, and a handsome specimen became a poor-looking cripple in a very short time."

From the terrace, shown in the photograph, it was once possible to obtain an unbroken view to Addington, but trees have been planted on neighbouring property, and they have grown high, until now the view from The Rookery is shut in disagreeably. But on a clear day you may see Epsom grand-stand—a poor compensation for Time's depreciating effect upon the place. The ground slopes steeply from the front of the house, where the lawn is kept very beautifully; and mark how "little" matters have been attended to in the beautifying of the terrace. Baskets and vases are filled with flowering plants, and Retinosporas, and even the skeleton lamp-posts have been utilised for planting Ivy-leaved Pelargoniums, which certainly help to screen the stiff, unpleasant-looking objects during the summer.

We next walk to the bottom of the lawn, and among some shrubs notice a pretty shelter—part of an arched walk 80 feet long, over which Roses are trained. The shelter is supported by eight iron pillars, each covered with a small-leaved Ivy, and the roof with a Banksian Rose. The old ice-well, 35 feet in the ground, has not been used since the common has been frequented by Londoners, and the ice is required by them for skating upon. There is a little house with a number of fine old Camellias in it. The walls are clothed by them, and a centre bed is filled by them. All of these have been planted about thirty years, and each of them cost a £10-note, most of them having come from Messrs. Lee's old nursery at Hammersmith. Some carpet-bedding is noticed, a fine lot of border Carnations, Sweet-Briar hedges looking very bright with numerous haws, and an old-fashioned kitchen garden, that suggests in its Peach and Apricot walls that it has nearly run its course. There is a good-sized Walnut-tree, and one is reminded of what can be done in a period of forty years, when Mr. Turner assures us that he once had the same specimen in a 6-inch pot.

In the kitchen garden is a locked-up place that looks not unlike a fruit or store-room, but upon entering it, one finds it is a covered bath in a mineral well, where the late Jas. Coater, Esq., then owner of the property, used to have daily dips. (This Mr. Coater was one of the exhibitors of plants in the days when the late Dr. Lindley was at Chiswick.) The water in the locality contains considerable mineral matter, is aperient, and is even injurious to many plants. In front of the covered well is an old sun-dial, but its capacity for usefulness was ruined one night by a policeman who was "on patrol," for it is said he had no person to arrest, and consequently arrested the brass fittings.

The fruit-garden affords much interest in its present condition. One can easily see that it was well done "once," but for years the garden has stood still, except in the matters of tending and keeping. There have been few renewals. Some of the old espalier, bush, and pyramidal trees are the most quaint objects possible (see fig. 105, p. 359). Numbers of them, too, have been trained according to a system once common in the case of Pear-trees, when they looked like Weeping Willows, and stones were attached to the tips of the shoots to bring them into a drooping position. The espaliers have grown out of all bounds, and some of them are twisted and crooked very curiously, being considerably over a hundred years old. One of the bush specimen Apple-trees is shown by fig. 106, p. 361, and is probably the variety Yorkshire Greening. Said Mr. Turner, "Some of the younger of the fruit-trees I grafted or budded in Penge Wood about forty-two years ago. I worked them in the spring of one year, and the next, such as had taken were removed to the garden here. But, in spite of little planting during late years, there have been good crops of Apples even this year, and some varieties are exceedingly plentiful in a good season, Ribeton and Blenheim Orange Pippins particularly so." Mr. Turner is an intelligent gardener; and though circumstances do not warrant the planting of young fruit trees and such like, he does his best to obtain crops from the old ones, and is successful. R.H.P.

NEW OR NOTEWORTHY PLANTS.

CEROPEGIA WOODL.*

THIS is a very interesting and beautiful plant, discovered in Natal by our old correspondent, Mr. Medley Wood, and introduced by Mr. William Bull. It is a trailer with very slender branches, bearing cordate suborbicular fleshy leaves, variegated with silver markings on the upper surface, and producing in the axils of some of the leaves small, globose, fleshy tubers, emitting roots by which the plant can easily be propagated. The flowers are about 1 inch long, pinkish or violet, with a slender tube distended at the base, and expanding above into a five-lobed limb, the five lobes dark purple, and united at the tips, so as to resemble a crown arching over the mouth of the tube (fig. 104, p. 358).

It will form an excellent basket plant in a warm-house, and is suitable for rockeries or other decorative purposes.

CHRYSANTHEMUM GOSSIP.

(Continued from p. 341.)

LEIGHTON HOUSE.—During the several years in which Mr. Mann has had charge of the gardens of Leighton House, Westbury, the residence of W. H. Laverton, Esq., Chrysanthemums have been made a specialty; and although exhibiting has for the past two or three seasons been discontinued, the show of blooms this year eclipses any preceding year. The gardener is one who appreciates the merits of older varieties, and produces splendid flowers from those which others discard in favour of novelties. Not that new varieties are absent from the collection, for they are there in strong evidence. It is pleasing to compare the old and the new standing side by side. For the conservatory or house decoration, plants with a few large flowers are much liked, and also for cutting. For prolonging the season of "Mums," early-flowering varieties are cultivated, and these produce fine specimens early in the month of October, the display continuing into December, by selecting the buds of the varieties of, mostly, the Japanese sections. At the time of my visit, the following varieties, the best in point of size, colour, and finish, were such as would be prominent in any open competition at provincial shows, viz., Lady Ridgway, Australie, and Eva Knowles, with enormous flowers; Duchess of Wellington, Pride of Exmouth, Ethel Addison, Edith Tabor, Mrs. C. H. Payne, M. Chenon de Leché, and Beauty of Teignmouth; Duke of Wellington, Phœbus, M. Hoste, Helen Owen, Australian Gold, Modestum, Graphic, Le Moucheronette, Souvenir de Petite Ami, Vicomte Roger de Chazelles, Pride of Maidenhead, Oceana, Simplicity, Deuil de Jules Ferry, Miss Mary Godfrey, Belle Mauve, Indiana, Pallanza, General Roberts, Madame R. Houles, Amiral Avellan, Colonel W. Smith, Octoroon, Mutual Friend, Swanley White, Sunstone, and Mrs. W. J. Godfrey.

The incurved Chrysanthemums, not grown to the same extent as formerly, had some extra good blooms. The plants grown for the production of specimen blooms numbered several hundreds, including early mid-season, and late varieties, and all were in the best of health, and freely flowered. Much credit is due to Mr. Mann for the excellence of the Chrysanthemums, and his general good management of the gardens. Visitor.

THE BOTANICAL HISTORY OF THE UVA, PAMPAS GRASS AND THEIR ALLIES.

THE genus *Gynerium* is best known by the two species *G. argenteum*, Nees, the "Pampas-grass" of our gardens and parks; and *G. saccharoides*, Humb. and Bonpl., the "Uva," the panicles of which, along with those of the first-named species, are sold for decorative purposes. *G. argenteum* is perfectly hardy in our climate, whilst *G. saccharoides* is a hot-house plant which is very seldom cultivated, and is only known to most people from its beautiful plumes, which are imported from America. This latter species, the *Gynerium saccharoides* of Humboldt and Bonpland, is the original species of the genus. The authors discovered it near Cumana, in Venezuela, and they described and figured it in their *Plantæ Equinoctiales*, ii., 112, t. 115 (1809). It was, however, already known to G. Marcgraf, a German doctor, who travelled more than 250 years ago in North-eastern Brazil between Pernambuco and Rio Grande do Nord. He described it, very accurately for his time, in his *Historia rerum Naturalium Brasiliæ*, p. 4 (1648), as *Arundo sagittaria*, the name referring to the use of the tops of the stems for arrow-shafts. Aublet, who explored French Guiana from 1762 to 1764, knew also the grass, and he called it *Saccharum sagittatum* (*Plantes de la Guiane*, i., 50; 1775). The affinity with *Arundo* as well as with *Saccharum* was suggested by a certain superficial resemblance with the common Spanish cane, or with the Sugar-cane. Humboldt and Bonpland were the first to point out the true structure of the spikelets, and the dioecism and the sexual dimorphism of the grass—characters which have since been recognised as constituting the "differentia generica" of *Gynerium* and *Arundo*. The consequence was that all the species which would otherwise have been referred to *Arundo*, but which were found to be dioecious, and more or less dimorphic, were included in *Gynerium*. Nees applied this principle first to a species which was till then known as *Arundo dioeca*, Spreng.; or *A. Selloana*, Schult.; and it became now *Gynerium argenteum*, Nees, our well-known "Pampas grass." He described also several new species of *Gynerium*, some of which were, however, reduced by him in a later publication. Steudel, Philippi, Doell, &c., added several more, so that the authors of the *Kew Index* have enumerated fourteen specific names under *Gynerium*. Adding four other names which they omitted,* and two further species which have been described since 1885; they are in chronological order as follows:—

- 1809 : *saccharoides*, Humb. and Bonpl., l. c.
 1812 : *sagittatum* and *procerum*, Beauv., *Agrost.*, 138 and 164 respectively.
 1820 : *argenteum* and *parviflorum*, Nees, *Agrost. Bras.*, 462, 463.
 1834 : *Neesii*, *pygmaeum*, Nees, and *speciosum*, Nees (name only), in *Meyen Reise u. d. Erde*, i., 380, 407, 484.
 1843 : *Quila* and *speciosum* (described) Nees, in *Nov. Act. Not. Cur.*, xix., Suppl. 1., 153.
 1854 : *zealandicum*, Steud., *Syn. Gram.*, 198.
 1864 : *atacamense*, Phil., in *Linnæa*, xxxiii., 289.
 1866 : *purpureum*, Carr., in *Rev. Hort.*, xxxvii., 419.
 1873 : *dioicum*, Dallière, *Fl. Ornam.*, i., t. 42.
 1875 : *roseum* Rendatleri, *The Garden*, viii., 165.
 1876 : *Levyi*, Fourn., in *Ill. Hort.*, xxiii., 137.
 1878 : *modestum*, Doell, in *Mart. Fl. Bras.*, ii., ill., 270.
 1883 : *arcuato-nebulosum*, Carr., l. c., lvi., 200.
 1889 : *triaristatum* and *Wolffii*, Sodiro, in *Ann. Univ. Quito*.

Of these, the following may be dismissed at once:—1, *sagittatum* (= *G. saccharoides*), a mere resuscitation of Aublet's specific name (under *Arundo*); 2, *procerum*, which name appears in the index, probably by error; 3, *Neesii*; and 4, *pygmaeum*, as "nomina nuda," and as synonyms of *G. Quila*, according to the author himself; 5, *Levyi*, reduced by the author to *G. saccharoides* in his *Mexicanarum Plantarum Enumeratio*; 6, *dioicum*, which is *G.*

argenteum, re-christened after its oldest synonym, *Arundo dioeca*.

Before I enter, however, on the somewhat difficult question of the validity of the remaining fourteen species, I must point out that they represent two very

differences more conspicuous, I put the description of the essential characters of both grasses alongside in two parallel columns—

G. SACCHAROIDES.
 Growing gregariously in more or less extensive reed-beds.

Rhizome—creeping.
Innovation shoots—extravaginal, viz., piercing the subtending sheath at the base, and growing up outside, and more or less remote from it; hence, the shoots coming up singly from the ground.

Culms—perennial; 12 to 30 feet high, to 2½ to 3 inches thick at the base, solid, woody below; internodes 40 to 60 and more, sub-equal, about 4 inches long (except the very lowest, which are much shorter, and the very long exserted peduncle), each with a bud at the base, which often grows out into an extravaginal branch; the lowest branches (to 10) recurved, rooting, transformed into stilts, the upper leafy.

Leaves—pretty evenly distributed over the culm, those near the base gradually withering away, leaving the stem naked to 4-14 feet above the ground.

Sheaths—sub-equal (except the lowest), about 6 inches long, slightly longer than the internodes, very tightly clasping the culm, the lower gradually withering away at length.

Ligules—very short, membranous, ciliate, at length breaking up into minute fibres.

Blades—as much as 12 feet by 3 inches, stiff in the lower part, spreading at right angles, then bent or recurved with drooping tips.

Peduncle—long exserted.

Sexual dimorphism—of the spikelets very conspicuous.

Spikelets—strictly two-flowered; glumes equal; rachilla not produced beyond the upper glume.

Glumes—sub-equal, oblong, acute, 1-nerved.

Valves—ovate-oblong, acute or shortly acuminate, 3-1-nerved, glabrous.

Stamina, 2.

Glumes—unequal, the lower as in the male, the upper twice the length or more, linear-oblong, subulate-caudate, slightly recurved, 3-nerved, firmer.

Valves—ovate, finely and long acuminate, 3-nerved.

Staminodes, 2.

—*O. Stapf*, *Kew*.

G. ARGENTEUM (PAMPAS).
 Growing in individualised large thick tussocks.

Rhizome—very short.
Innovation shoots—intravaginal, viz., growing up within the subtending sheath; hence the shoots bunched with the mother shoot.

Culms—biennial; very short (1 to 1½ inch) in the first year, far overtopped by the sheath; when flowering to 3-6 feet high (exclusive the panicle), of the thickness of the little-finger, solid, internodes to about 18, the lower very short, the following gradually longer, from 1 inch to 2 to 2½ feet (the peduncle), only the very lowest with buds (innovation buds); culms hence simple.

Leaves—mostly crowded at the base.

Sheaths—increasing in length from the base upwards, from 2 inches to 2½ feet, several to many times longer than the internodes (the uppermost at length almost equalled, or even exceeded by the peduncle), the lower rather loose in the upper part, the others tightly clasping each other.

Ligules—a dense line of fine silky hairs.

Blades—as much as 5 (rarely 6) feet by ½-inch, very flexible, sub-erect, then long recurved, turned 180° near the curvature, so that the upper and under sides are reversed.

Peduncle—enclosed or shortly exserted.

Sexual dimorphism—of the spikelets slight (apart from the genitalia).

Spikelets—3-6-flowered; the uppermost florets more or less reduced or rudimentary.

Glumes—sub-equal, very narrow, linear, long tapering 1-nerved.

Valves—lanceolate, produced into a very long and fine acumen, 3-nerved, very scantly hairy, or quite glabrous.

Stamina, 3.

Glumes—as in the male.

Valves—as in the male, but always more copiously hairy.

Staminodes, 3.

(To be continued.)

FIG. 104.—*CEROPOGON WOODII*: LEAVES FLESHY MARBLED, FLOWERS VIOLET. (SEE P. 357.)

distinct types, which differ in their mode of growth, as well as in their floral structure. One type is represented by *G. saccharoides*, while the Pampas-grass may be considered as representative of the other group. In order to facilitate comparison, and to render the

"MANUEL DES CULTURES SPECIALES."—Dr. PAUL DE VUYST has issued, through M. OCTAVE DOIN, 8, Place de l'Odéon, an excellent manual on the cultivation of Potatoes, Carrots, Beetroots, Chicory, various cereal and forage plants, Flax, Hops, Tobacco, &c., together with essays on rotations. We gather that the work has been translated from the Flemish. In any case, from the manner in which the teachings of science have been brought to bear on practice, this seems to us one of the best handbooks of its kind.

SPECIES OF SOLANUM.

IN the issue of the *Gardeners' Chronicle* for October 30, a figure of *Solanum cornutum* grown in the Cambridge Botanic garden was given. Other subtropical *Solanum* cultivated this year in the same garden are the following:—

S. aculeatissimum.—According to some visitors this is the most beautiful of all. It grows about 2 feet high, and branches freely, producing a wealth of lovely pale green leaves protected thinly with violet-coloured spines. They are broadly ovate in outline, prettily waved, and cut into short segments. The branches are spreading, violet-coloured on the sunny side, and thickly covered with spines. The flowers are white,

* No doubt with good reason, as the descriptions were utterly insufficient and untechnical. As they, however, have been taken up in various journals on horticulture, they will be mentioned in this place.

is, and pretty, but not conspicuous, and are d by attractive fruit, mottled with pale and en. The young leaves, under a summer sun, ed with violet, and this colour, in combina- the pure cool green of the older leaves, is rly charming. Its habitat appears to be

purpureum.—This is certainly one of the markable and striking. It grows about igh, and branching thinly, exposes freely to dark purple stems, which are covered thickly g stout spines of the same colour, all as sharp es, and pointing slightly downwards. The oo, are thinly provided with these spines, in an inch long on the upper side, and rather he lower. The finer leaves are nearly a foot l all are deeply cut into narrow lobes; the urface is dark green in colour, with mid-ribs

on the upper side, and become dark green with silvery margin, then exposing the pale green or nearly white midribs. They are broadly ovate, with cordate base, and sinuately-lobed margin. The flowers are white, about the size of a Potato-flower, and they are succeeded, after an exceptionally hot summer, by yellowish fruit. This species requires to be sown the year before it is planted out, and if the young plants have been starved in pots it appears to matter little, for when shifted on in the spring, good growth soon follows. It is a native of Abyssinia.

S. robustum.—There is perhaps no other so stately and handsome as this well-known species. It grows in an ordinary season about 4 feet high, and produces leaves nearly 2 feet long and about 16 inches broad, furnished on both sides with broad brown spines. They are elliptic-ovate in outline, boldly sinuated and strongly decurrent. The entire plant is more or less

the best. It attains a height of about 4 feet, with single stem, bearing dark green leaves nearly 2 feet long; they are broadly ovate, cordate at the base, and divided, about half-way to the midrib, into bold segments, five or six on each side. The spines are not a feature, but numerous short ones are borne on the petioles and midribs. Its habitat is not recorded.

In the Cambridge Botanic Garden these *Solanums* form a very ornamental feature. They are cultivated in a large bed, about 16 feet across, in groups of about five of each species, and usually some other subjects of interest and beauty are introduced, partly for the purpose of occupying the ground until the *Solanums* themselves can utilise it all. They must have plenty of room; rich soil is essential at all stages, and with the exception of *S. marginatum*, *S. robustum*, and for safety's sake, *S. Warscewiczii*, all may be raised from seed sown early in March.

FIG. 105.—THE TERRACE AT "THE ROOKERY," STREATHAM COMMON. (SEE P. 357.)

white. The flowers are greenish and rather cuous, producing small green fruits, with darker colour. It is a native of Brazil.

marginatum.—This is the strongest-growing of all, g a height of 6 feet, and producing several s. It is quite spineless and entirely glabrous, as blackish and foliage dark green. The re above 9 inches long, and are divided into ree to seven narrow divisions, with unbroken and tapering to a point. The flowers are urple in colour, and somewhat ornamental, ed by egg-shaped green fruit. Under the ame there is a figure in the *Botanical Maga*-349. It is properly called *S. aviculare*, and is as the Kangaroo Apple. It is indigenous to ia and New Zealand.

marginatum.—Of all the species, this is one of known, it being a common sub-tropical in , in the London parks and elsewhere. It grows ½ feet high, and is remarkable for the snow-omentum with which the stems and leaves are . The older leaves lose much of this covering

covered with ferrugineous tomentum, which gives it a very characteristic appearance, and colours the young leaves with bright reddish-brown. The stems are perfectly erect, and begin to branch only at the end of the season, when a few white flowers are produced, never in our climate succeeded by fruit. Seeds must be sown the preceding year. It is a native of Brazil.

S. sisymbriifolium.—This is distinct in character, differing from all other species, and is a plant well worth growing. The stems branch freely and spread, with a general height of about 4 feet. They are covered with orange spines, and bear leaves of moderate size, deeply pinnatifid, with divisions wavy and lobed, almost Fern-like in effect. The flowers 1½ inch in diameter, vary in colour from violet to white, and add considerably to the beauty of the plant. The fruit of a globose shape, and bright red in colour, is attractive. This plant is known in gardens as *S. Balbisii*, and seeds are received under various names. It is a native of Brazil.

S. Warscewiczii.—For its fine foliage this is one of

The treatment of the plants should be so calculated that they can be planted out from 48-sized pots early in the month of June. *S. giganteum*, and one or two other species, have been grown, but none do so well as the above. *R. Irwin Lynch*.

RAYLEIGH VICARAGE.

SITUATE at the top of the main street of the little Essex town of Rayleigh—itself in an inviting position—the picturesque vicarage enjoys an enviable site. Embowered amidst trees, it embraces from parts of its old-fashioned garden a prospect extending over many miles of the peninsula lying between the rivers Crouch and Thames. The land by the rivers is flat and rather monotonous, but there are visible hills in the distance. Afar off in a south-westerly direction may be descried Danbury Palace, the former residence of the Bishop of St. Albans; and in another direction the woods everhanging Billericay. At a greater elevation than the vicarage are the remains of earth-works known locally as The Mound, and ascribed to

Sweyne, the owner of the place at the time of the compilation of *Domesday Book*. Altogether, the surroundings of the place have numerous attractive features.

On the occasion of my visit, the hospitable vicar (Rev. R. C. M. Rouse, M.A.) was my guide, and he had many noteworthy features to point out in his garden. Although the vicarage, with its velvety lawns opposite north and east fronts and adjacent garden, is situated only a short distance from the highway, it is completely shut out from public view by large, handsome trees, and only becomes visible on the visitor reaching a bend in the drive leading to the front doors. Among the trees referred to above may be mentioned a grand specimen of *Platanus orientalis*, having a straight, clean stem for about 20 feet, and a girth of 10 or 12 feet, and a large, uniformly-shaped head; Norway Maple and Sweet Chestnuts are also noticeable trees. The other fine specimens consist of Deodar Cedar, double-flowered Cherry, and a double-flowered pink Hawthorn, with a thin stem but an enormous crown; a good example of *Araucaria imbricata*, about 55 feet high, having a main stem about 3 feet in circumference close to the ground, and healthy branches brushing the closely-shaven lawn on every side but the south-west, the only exposed point.

The light loamy soil resting on clay is just suited to the requirements of this species, and the tree bears cones of a size similar to those I observed on a tree in the grounds of Alderbury Vicarage, Salisbury, a few years ago, a fact that was noticed in the *Gardeners' Chronicle* at the time, both fine specimens, and growing under like conditions as regards situation and soil. Furthermore, I may mention that I have seen several good specimens of this tree in robust health growing in the peaty soil of Branksome Dean (Lord Wimborne's place near Bournemouth), and in the midst of Pine-trees, as showing that some trees flourish up to a certain age in soils of quite an opposite description, so long as the needful shelter is afforded them, and that they only exhibit signs of distress when the roots have ceased to extract nourishment from the soil, and the top-growth ventures to push above the shelter hitherto afforded by neighbouring trees and shrubs.

The finest specimens of the tree *Pæony* (*Pæonia moutan*) which I have hitherto seen were going out of flower at the time of my visit (May). These are growing in a flower-bower; and they are about 6 feet high, and as much through, the individual flesh-coloured flowers being some 7 or 8 inches in diameter—full solid blooms. The kitchen garden was well-cropped with seasonable vegetables; and the gardens and glasshouses reflected much credit on the "vicar's gardener," H. W. Ward.

METHODS OF PROPAGATION.

(Continued from p. 286.)

HARDY SHRUBS, &c., FROM CUTTINGS.—The genus *Ligustrum* (Privets), among which *L. ovalifolium* is pre-eminently the most useful, may be struck from cuttings taken at any time when the sap is not in active circulation, but the best time is during September and October, and the pieces may be put closely in rows in a shady border, from which they will need to be lifted and transplanted in the following autumn.

Millions are used in London and other towns, as all the varieties resist the deleterious action of coal-smoke. It has, however, a rival in the Japanese *Euonymus*, especially near the sea, where the broad-leaved Japanese Spindle-tree grows with such vigour that it quickly forms bright green hedges, even within the spray of the sea. This *Euonymus*, of course its variegated forms, may be raised from cuttings at any period of the year, but the best result is procured by taking the cuttings and bedding them in the autumn. There is no shrub that likes the sea-shore better than this, except the Tamarisk (*Tamarix Gallica*), which will grow right down to the tide-line, and seems to revel in the salt spray. A very singular fact may be noted, that when this plant is growing miles from the sea, if one puts the tongue to a growing shoot it tastes of salt, and on stirring a weak

solution of silver nitrate with a bunch of the foliage-covered twigs, a turbidity is caused in the liquid, showing the formation of silver chloride, through the presence of minute quantities of common salt.

While speaking of plants of the seaside, I must not forget the New Zealand Speedwells and their varieties, *V. Andersoni* and *V. Traversii*, which in the south and west districts flourish exceedingly, and yield their blue and white spikes of flower most freely in spring and autumn. All are easily increased by cuttings of the young wood, planted in the open border, or under handlights.

A pretty little evergreen shrub of late introduction, the *Olearia Haasti*, which yields its minute composite white flowers in such profusion in May and June. It may be easily propagated by cuttings of the young wood taken with a heel. There are still among evergreens the *Mahonias*, *Skimmias*, and hardy *Heaths*; and among deciduous shrubs, the *Elders* in variety, and *Lilacs*, all of which can be increased by cuttings of the ripe wood taken in the early autumn, and bedded-in in light soil under handlights, where they will root quickly and make plants fit to plant out in the following autumn.

Fruit-stocks.—In addition to trees and shrubs, there are some very important fruitstocks raised from cuttings that are in constant request in nurseries, while Gooseberry and Currant bushes of all kinds are thus obtained. First, the Paradise stock, so useful in budding and grafting Apples to form early fruiting, and fertile pyramids may be increased as follows:—Take a straight piece of ripe wood about a foot long, and cut it square at the thick end and diagonally at the point. Such cuttings may be inserted in rows in moist, fresh soil, and should be trodden in firmly. Should this be done in early autumn, before all the leaves have being shed, the young stocks will have rooted freely, and be ready to plant out the following autumn, and if well cultivated, should be ready for budding by the following July; but it is advisable to give them at least two years before commencing to work them. The other stock is the common Quince, used to work Pears upon, in order to induce a greater production of fruiting-spurs.

The cuttings should be made in the same way as the Paradise stock, but need not be quite so long, and they should be bedded in some spot where the soil is rather moist, such as the banks of a stream, or the side of a ditch, as the Quince loves moisture. *Experience.*

(To be continued.)

FORESTRY.

PLANTING AND THINNING SPRUCE FIR WOODS.

I THINK a great deal of nonsense is often written about the German system. For instance, an example of the poor results of imitating the German methods was quoted in the column on forestry a few weeks back. The writer described a plantation of Spruce which had never been thinned for fifty years, and imagined it an exact model of the fine forests of the Black Forest. He was surprised when they were blown down, and derided all other systems but the extremely wasteful one of open woods.

The sylvicultural system most common in Germany is the "clear cutting system," and this species commonly grown is the Spruce. The Spruce is grown in nurseries, and planted out in the forest, at about three to five years of age, at a distance generally of 3 by 3 feet apart. Naturally, the struggle for existence commences at a very early age, and then the forester steps in and makes the first thinning, or rather clearing. By the time the Spruce is fifty years it will have been thinned several times. Thinning is a process which needs considerable experience and practical knowledge. The object of the German foresters is to obtain tall trees with well-developed crowns, fair girth, and above all, no large branches below the crown. The proper density is reached when the shade is just sufficient to

kill the lower branches and any undergrowth of weeds. If there is an undergrowth of weeds it will suck out moisture and salts necessary for plant absorption, and greatly impoverish the soil. The other extreme, namely, insufficient thinning, is even more disastrous, and was the mistake made in the Spruce wood referred to above. The crown becomes cramped and small, so that the trees cannot assimilate sufficient carbon dioxide from the air, and lose all vigour. Also in the struggle for existence, the trees mutually draw one another up in height in their efforts to obtain more light, and the thin, brittle, wand-like poles that result are at the mercy of the first gale of wind. I very much doubt also if the species was suited to the locality. It is well known that Spruce has very superficial roots, and unless it has plenty of moisture, it is not likely to thrive; and for various other reasons, Spruce does not appear to be suited to the greater part of this country.

I should like to add a word in favour of properly stocking a wood. If a wood is over-thinned, as is generally the case in England, the trees are able to increase considerably laterally, as well as in height growth; and since the assimilating surface is far greater than in a less open wood, the result is a greater increase of volume. On the other hand, in a wood that is properly stocked, the number of trees per acre is far greater, and nearly all the timber is in the stem, and not in the branches. The trees also are more even grained, cylindrical, and free from knots in the wood. Besides the quality of the wood, the great defect of open woods is that an undergrowth of weeds can spring up. This sucks up moisture and salts necessary for plant nutrition from the substratum of the soil, and prevents dew reaching the soil. In any other country less suitable to the production of timber, this would be absolutely fatal.

If, however, the reason for open woods is that quick returns are required for the capital invested, I think "the coppice with standard" system could be a happy and far greater success. H. C. W.

VINES AT AIRTHREY CASTLE, NEAR THE BRIDGE OF ALLAN.

AIRTHREY has long been famous for its noble lake, expansive park, fine Sycamores, Beech, Oaks, Chestnuts, and other timber trees; its thriving plantation of the choice Conifers around the mansion, and grand clumps and masses of *Rhododendrons* and *Azaleas*. Situated between the mansion and the kitchen gardens there are some immense masses of *Kalmia latifolia*, possibly the finest in Britain, from 6 feet high and upward, which bloom in great profusion every year. The kitchen garden is warm, sheltered by the bottoms of the rising woods, and is thus specially well sheltered on two or three sides. It is enclosed by walls well clothed with fruit trees, which were rather thinned of their fruits this year, through the snaps of cold that are so often felt in the valleys in blossoming time. The standards and bushes fringing the main walk, however, mostly escaped the spring frosts, and bore good crops this year. The kitchen and fruit garden was enriched by some six or seven wall-furnished, skilfully-planted borders of herbaceous perennials and annuals. Among these *Hollyhocks*, *Dahlias*, *Phloxes*, *Delphiniums*, and immense clumps of the pure white *Anemone japonica* were specially prominent. A fine border of *Roses* was also a notable feature of the kitchen garden.

Passing rapidly through it, the ranges of fruit-houses was reached. This consists of six divisions—the first, a Peach-house furnished with two fine fruitful old trees of *Stirling Castle*, and *Royal George* Peaches. The next to this was a vineyard, planted in May of this year, with *Appley Towers*, *Lady Hatt*, *Mrs. Pearson*, *Cooper's Black*, and *Madresfield Court* Vines, and here, leaf and "timber"—the latter is the right word—were all that could be desired.

The third house is also a vineyard, planted with *Hamburgh*, the Vines in their fourth year, and studded with the finest, blackest bunches that I have seen. It is a common failing of this fine Grape to lose its dark colour as it increases in sweetness during

the late autumn and winter. This deterioration is sometimes attributed to a lack of ventilation and of water at the roots; in some cases the colour is lost by the exposure of the bunches to the occasional strong rays of the autumn sun, and possibly this is in part what Mr. Rutherford suspects is the case here. Certain it is, however, that the fact that most of his finest bunches were papered at the time of my visit showed this. One hardly knew which to admire the most, the size and substance of the foliage, the cinnamon-brown tint of the young shoots (which had almost the ring of metal when tapped), or the jet blackness and fine bloom of the berries.

The fourth viney contained Muscats of Alexandria in their sixth year, which were carrying crops, fine in bunch, berry, and finish.

The fifth viney entered is a mixed one of late varieties in their second year, each carrying a test bunch or two to prove, were proof necessary, their reserve of vitality in the present, and their ample and abiding performance in the future. A cool regimen from start to finish is the surest receipt for keeping Mrs. Pince Black Muscat as black as sloes. I travelled many years since from London to Exeter to learn this lesson. I found the original Vine growing almost in an open shed in fine colour, and have never forgotten the lesson, nor known the cool treatment to fail. Hamburg treatment rather than Muscat or Alicante colour Mrs. Pince and Muscat Hamburgs the best. The sixth house was filled with Royal George Peaches and Elrue Nectarines.

Behind this chief range of glass are the usual sheds, potting-benches, stoves, and a Mushroom-house white with "buttons," Melon and Tomato-houses being filled with a fine lot of Chrysanthemums for winter work. Greenhouses and plant-stoves for decorative purposes, cut flowers, &c. Near here, too, is a thriving collection of alpine and herbaceous plants on picturesque masses of rockwork, and on the gardener's cottage close by a magnificent plant of the *Wistaria sinensis*, which clothes it with beauty every year.

Vine growers and showers of the present and the future will have to reckon with those youthful Vines at Airthrey, as in Mr. Rutherford's able hands, and with many factors of soil and site to back up his undoubted skill, these Vines are bound to beat all their past records. D. T. F.

THE ROSARY.

ROSES, WHAT TO PLANT, AND HOW TO PLANT THEM.

(Continued from p. 325.)

In the Tea-scented class there have been a few good additions; probably, the most generally popular Rose is Maman Cochet—but as it was sent out in 1893, and as it is very generally grown and known, there is no need to say anything about it. Sylphe, sent out by Messrs. W. Paul & Son in 1895, is a Rose which all lovers of Teas ought to be anxious to obtain; it is a very vigorous and free-flowering variety, and although the form is globular, and not pointed as Teas I think ought to be, it is sure to find favour.

Muriel Grahame, which is a sport from Catherine Mermet, obtained by Mr. Brown, of Reigate, and put into commerce by Messrs. Alex. Dickson & Sons, Newtownards, has received such distinguished honours that it is sure to be in great demand: it retains all the good properties of the Rose from which it sported, which it resembles in colour (except that it has a pinkish centre); but when a Rose has obtained the Gold Medal of the National Rose Society, and has twice been awarded a Silver Medal as the best Tea Rose in the exhibition, it needs no further recommendation. Some have indeed doubted whether the sport will be constant, but judging from the analogy of other Tea Roses, I think we may fairly conclude that this will remain true.

Empress Alexandra of Russia, a fine high-coloured Tea sent out by the Waltham Cross firm, and has been much admired during the past season; the colour is rich lake-red, shaded with orange, a peculiar combination but very striking. There are several other Tea-roses which I find recommended in various ca-

logues, but they have not been brought forward so that one can judge safely concerning them, and now that there is such a large number of fine varieties of every colour, it is wiser to wait a little before adding them to collections: such are Emile Gonin raised by Guillot, Madame Louise Gravier raised by Gamon, Souvenir de Jeanne Cabaud by Guillot. As two of these are from the celebrated Lyons firm, which has given us so many good Teas, we may hope that they may be valuable additions to our collections.

With regard to hybrid Teas, there has been a considerable addition during the past two years; the cry has gone forth that they are the Roses of the future, and that for all decorative purposes, and for continuous blooming, they are to be preferred before all other classes. I have always contended that it was a mistake to make a separate class of them, and with the obstinacy which I suppose belongs to old age, I still cling to my opinion. The confusion which I thought would be likely to arise seems to increase

FIG. 101.—AN AGED APPLE-TREE, AT "THE BUCKERY," STREATHAM COMMON. (SEE P. 357.)

daily; thus, I saw that a very well known amateur has, in a contemporary, started the notion that Mrs. John Laing ought to be added to this class—at least, the writer says it has Tea blood in it, therefore it is a hybrid Tea. One of our largest growers of Roses said to me the other day that La France, which was sent out as an H.P., and was then transferred to the H.T. class, is really a hybrid from a China Rose and not a Tea Rose; while a writer in one of your contemporaries last week says he cannot understand why Kaiserin Augusta Victoria should be ranked as a 'hybrid Tea,' evidently agreeing with the late Mr. Geo. Prince and others, who regarded it as a pure Tea. In fact, I see in one of our most accurate Rose catalogues that it is classed amongst the hybrid Teas, and the following remarks are given in the same catalogue on the whole section:—"In some cases the hybrid perpetual percentage is so marked, that they should rather be classed as hybrid perpetuals." Exactly so; then why should they have been separated? Some of these, too, are single, like Bardou Job, or semi-double, like Gustave Regis. Amongst the newer varieties which, under whatever class they may be placed, are deserving a place in our gardens from their freedom of flowering and beauty of colouring, may be classed—

Madame Pernet Ducher, a Rose which has sometimes been overlooked. It is described as a canary yellow, with a light tint of cream on it.

Marquise Litta (Pernet Ducher, 1893) is a brilliantly-coloured Rose, of good constitution, and very free-flowering. Two other Roses, which no one will regret adding to their collections, are Madame Pierre-Cochet (N.) and George Nabonnand (T.), the former very striking in its colour, which is deep orange-yellow, somewhat in the style of William Allen Richardson. The latter, while very beautiful for the garden, is also found often available for the exhibition stand; it is a pale flesh, shaded with rose, of a good form and substance, and an excellent grower. There are two other Teas which I think promise well—

François Dabreuil, one of the darkest of the red Tea Roses, full and of good form, but I fear it has got a touch of that violet shade, which turns badly when it is a little past.

Princess de Venosa, which I do not find in many catalogues. It is said to be fawn-yellow, shaded with gold and violet. I had a nice bloom of it the other day (November 11), but I am glad to say I did not discover any traces of violet.

There is another class of Roses to which attention has been drawn of late years, viz., the China or Bengal Roses, the old monthly Rose, whether in its common form in the dark variety. The latest additions to this class have been—

Laurette Messimy, a rose shaded with yellow, very pretty and distinct.

Duke of York, rosy pink and white, in out-door cultivation the pink becoming crimson.

Irene Watts, a white Rose, tinted with salmon-pink; and above all,

Queen Mab, which has been exhibited at the Drill Hall by Messrs. W. Paul & Son, and has been much admired. It is well suited for pot culture, as the plants are covered with beautiful blooms of a colour an apricot shaded with orange and rose. These will form admirable plants for the front of Rose-beds, and are also well adapted for pot-culture. *Wild Rose*.

(To be continued.)

ROSE: CLOTH OF GOLD.

This much-lauded Rose is sometimes called Chromatella, and was sent out in 1843. Until Maréchal Niel appeared in 1864, everyone raved about it as being the best yellow Rose we had.

During the summer of 1893 I saw a grand old plant, the main stem covered with lichen, 15 inches in diameter [?], in full flower. Since then, only a few stray flowers have appeared. Last July, I saw an old plant, of the same growing, upon a mill-house in mid-Sussex. The aspect is north-east, and sheltered by a belt of high trees and shrubs. The plant was simply covered with pale sulphur-yellow blossoms.

Ten or twelve years ago, we had several maiden standards left over from the previous season's working. Almost without exception these flowered the following summer, but most were killed before passing through a second winter. In spite of these two grand old specimens in this neighbourhood, I should be very chary about recommending Cloth of Gold for any but an exceptionally warm and sheltered position. The knife should never touch it, except to cut away frost-bitten wood.

A seedling from this, named Comtesse de Beaumetz, was introduced by Nabonnand in 1876, but is not sufficiently distinct. It is rather singular that such an authority as Mr. William Paul should class this with the Noisettes, and yet put Maréchal Niel among the Teas. He also has Bouquet d'Or as a Noisette, but Gloire de Dijon as a Tea; but if we venture into comparing and distinguishing these two classes, we soon get into a hopeless muddle, and the blending of them under the title of Teas and Noisettes by the National Rose Society was a good thing. A. P.

ORCHIDS AT "THE DELL," EGHAM.

THE fine show of summer-flowering Cattleyas, and the gorgeous display of summer and autumn-flowering Denrobiums in Baron Schroder's famed collec-

tion having passed away, the display is continued by the varieties of *Cattleya labiata*, *C. aurea*, and *C. Bowringiana*, which with a few hybrid *Cattleyas* and *Laelio-Cattleyas* (among which *L.-C. x Statteriana* is very noteworthy), which brighten the large house devoted to *Cattleyas* and *Laelias*. Among the specimens, several were noted of more than general interest by reason of their being old inmates of our Orchid-houses. Of these perhaps the most interesting is the plant of the original *Cattleya labiata*, and which was probably obtained from division of a plant which has been in this country for upwards of half a century. Many similar examples of the success of good cultivation could be found in The Dell collection, where plants obtained from Rucker's and from Day's collections are still growing with unabated vigour, two large pans of *Sophranitis grandiflora* originally belonging to the latter now sending forth some twenty or more flowers each. Similar experience was noted among the varieties of *Coelogyne cristata*. In a house devoted to these plants there are huge plants of *C. cristata alba*, and the Chatsworth and other varieties, some of which have been grown up from small plants, with but three or four pseudo-bulbs, and some of which now take four men to move them about conveniently.

The *Odontoglossum*-houses contain most of the valuable and beautiful varieties which have appeared, such as *O. crispum* *Schroderianum*, *O. c. Ballantinei*, *O. c. apiatum*, *O. c. Stevensii*, *O. Pescatorei* *Schroderianum*, *O. P. Veitchianum*, &c. It is a thing almost unknown to lose any of these grand varieties, and although propagation is very slow, still duplicates of many of them have been secured by division, and that, too, without interfering with the flowering of the plants, most of which are again sending up very stout spikes. Only a few are in flower at this season, but the varieties of *O. Rossii majus*, *O. Cervantesii*, and some others of the smaller species still bear flowers.

In the *Masdevallia*-house were observed in flower some good plants of the showy *M. macrura*, the small and neat *M. Wagneri*, the pretty pale yellow hybrid *M. x Hincksiana*, and the blush-white *M. x McVittie*, as well as the singular *M. (Scaphosepalum) pulvinaris*, and others of botanical interest. Here too instances of sustained good condition and vigour were some large panfuls of *M. racemosa* (*Crossii*), which for many years used to baffle the endeavours of importers and cultivators; and several dense plants of *Cryptophoranthus Dayanus*, all propagated from an original bit of moderate size. Mr. H. Ballantine, the gardener at The Dell, has a happy method of finding out the right quarters for his plants, and a no less praiseworthy plan of "letting well alone" when they are thriving satisfactorily; and the Baron himself often makes a suggestion for the improvement of the condition of a plant, which generally has the desired effect. In one of the houses a good show of *Vanda corulea*, some of the varieties having very large flowers of a charming tint of blue, was noted; and some plants of *Vanda Sanderiana*. The varieties of *Vanda tricolor* and *V. suavis* are in fine condition, promising well for bloom. In the small intermediate houses were remarked many large-flowered varieties of *Laelia pumila*, and some *L. Dayana*, several varieties of *Lycaste Skinneri*, *L. cruenta*, *Oncidium Forbesii*, *O. pretextum*, *O. varicosum*, and other *Oncidiums*, &c.

In the large stove, the centre of which is occupied by gigantic plants of *Anthuriums* and other foliage-plants, is the remnant of a splendid show of *Dendrobium Phalaenopsis Schroderianum*, including a very pretty clear white variety. Many grades of colouring are represented, but in size or colour none equals the original plant, which was in The Dell collection for some years before the species began to be imported in quantity. Also, very finely in bloom were good specimens of the large white *Dendrobium formosum giganteum*, the fragrant *D. aureum*, &c.

Among the *Cypripediums* in flower, *C. lusigne* *Sanderæ* is a splendid example, its soft yellow and white flowers being far superior to other yellow varieties beside it; or, indeed, to all of the other *Cypripediums* at present in bloom at The Dell.

The winter-flowering *Calanthes vestita*, *Veitchi*, and the still finer hybrids raised at The Dell, the best of which is *C. x Baron Schroder*, have formed gigantic, healthy-looking pseudo-bulbs, and are sending up a profusion of stout spikes; the two immense plants of the yellow *Sobralia xantholeuca* are also well set with buds; the collection of *Phalaenopsis*, which in times past has been the least satisfactory of the subjects grown, are at last affording good results; the house of *Laelia anceps* will in due time be a grand sight; and the other fine things grown here are well up to their usual standard of excellence.

The large house of *Chrysanthemums* is filled from end to end with a splendid show of very fine blooms, and most of the best new kinds are represented.

NURSERY NOTES.

TURNFORD HALL NURSERIES, NEAR CHESHUNT.

PLACED end to end it is calculated that the glass-houses on Mr. T. Rochford's vast establishment would extend over ten miles, and both the structures and the plants grown in them are kept in such perfect condition that they would put most of our best private establishments to shame in the matter of order, cleanliness, and good culture, qualities which Mr. Rochford holds as much a necessity as a virtue to the grower of market plants on a large scale. Orchids have of late years been extensively added to the number of plants grown for sale, and for supplying cut flowers, and remarkably well has the culture of this class of plants been grasped. So much is this so, that the large quantities of showy species here grown compare favourably with the remainder of the excellent stock. Two or three of the long and comfortably-heated houses are filled with *Cattleya labiata*, whose brightly coloured flowers make a fine display. As they approach maturity they are cut and sent to market, where they find a ready sale. A house of *Cattleya Warszewiczii* has many very richly-coloured flowers. These command even a higher price than *C. labiata*, but as the plants are less productive they would not be so profitable. *Cattleya aurea* is a favourite in the market, its large yellow and purplish-crimson fragrant flowers are liked by everyone, but owing to difficulties in the way of its importation, some thousand or so plants are all that have been stocked as yet. These are growing splendidly, and many are in flower. *Cattleya Gaskelliana*, *C. Mendeli*, and *C. Mossii* are also grown in quantity; and a batch of *C. Trianae* are establishing, to furnish flowers in the dull season.

Several houses are devoted to *Cypripediums*, of which the varieties of *C. insigne* take the lead because they can be supplied in quantity, and they are among the best for the purposes of cut flowers on account of their durability. A large quantity of white and coloured varieties of *Laelia anceps* is grown, up to their best, and the plants are plentifully furnished with flower-spikes; a quantity of *Odontoglossum Rossii majus* give a good show of bloom; and a large batch of *Laelia pumila*, of the very best type, has many large and richly-coloured flowers upon the plants. This importation produced one pure white variety of great beauty, and another now in bloom promised in the bud to be equally good, but on opening it has developed colour.

For market purposes, Mr. Rochford finds the old species, which have always been favourites in gardens, still hold their own. Hence, he grows *Dendrobium nobile* largely, and the recent importations have contained many fine varieties. Of these the most remarkable is the pure white form, in which the colour seen on the labellum in other white forms is entirely obliterated, the plant being the first true albino furnished by the species. In one of the houses a batch of *Vanda corulea*, giving a good show of light-blue flowers, was remarked, and among them the charming *V. corulea* *Rochfordiana*, a pure white form with a pink lip, which secured an Award at a recent meeting of the Royal Horticultural Society.

Other showy species that are grown in quantity, and are doing well, and in many instances contributing a good show of flowers, are *Odontoglossum grande*, *Oncidium tigrinum*, *O. Papilio*, *Cypripedium Lawrenceanum*, *Laelia Dormaniana*, *Dendrobium formosum giganteum*, *D. Phalaenopsis*, *Miltonia spectabilis*, and in lesser quantity many other good species. Several houses are used for *Odontoglossum crispum*, which it is intended to grow largely, and with a view to that object fresh plants are being imported.

PALMS AND FERNS.

These useful decorative subjects fill numerous houses, there being many thousands of *Kentias*, from the small plant up to the large specimen reaching up to the ridge of the large Palm-house, and all are alike perfect in foliage, fresh, and spotlessly clean. *Latania borbonica* occupies a leading place among Palms, and one long house is filled with a new variety of it with bright, light yellow-coloured foliage—a charming novelty. *Cocos Weddelliana* is grown in quantity; also *Corypha australis*, *Seaforthia elegans*, and all the other species, which are of quick growth and neat habit. One warm house has a number of beautiful specimens of the rare *Licuala grandis*, and here and there are other rare species, which are cultivated for the sake of variety.

The Ferns, of which hundreds of thousands are grown, are principally of the known market sorts, such as *Pteris serrulata*, *P. tremula*, *P. cretica*, and the many fine hybrids which the growers of market Ferns have been instrumental in raising; also *Polypodium aureum* and *Adiantums*, among which *A. cuneatum* takes the lead.

Of other foliage plants, *Pandanus Veitchi* fills a large house with very pretty white and green variegated plants. Some houses of *Crotons* and *Dracenas* are brilliantly coloured. Of the latter, in spite of the many new varieties, imported or raised of late years, *D. terminalis* and *D. t. stricta* form the bulk of the kinds grown.

One house is filled with *Cycas revoluta*, the foliage of which is used for cutting, and the supply seldom equals the demand. *Asparagus plumosus* is also grown extensively for cutting. One house is brilliant with the scarlet spathes of *Anthurium Scherzerianum*, several others are white from end to end with fragrant sprays of *Lily of the Valley*, a supply of which in flower may be found at Turnford Hall every day in the year. The crops, which cannot be got by forcing, are secured by retarding immense quantities in freezing chambers, established by Mr. Rochford at great cost, but which he considers among his best business transactions. In these chambers the *Lilies* are kept at about 5° under freezing-point, Fahr., and with snow on the wall of the chambers, even in the height of summer, and here they can be retarded for any reasonable time without injury to their flowering properties, and so taken out and placed in warmth for flowering as required. It is intended to use this system of retarding flowers more extensively in other subjects, as well as *Lily of the Valley*, and experiments will doubtless furnish some interesting facts.

The houses which have been used for *Tomatoes* are now filled with excellently-flowered *Chrysanthemums*, their blooms cut with a good length of stalk daily, being taken over to the well-appointed buildings where the market flowers are packed, and where in a few minutes, in the hands of those skilled in the work, they are put up in bunches, which, though seemingly carelessly done, it would be difficult to improve on, no matter how long a time was spent on the work. Still in the open ground or under slight protection, are many thousands of *Lilium candidum*, *L. Harrisii*, and other *Lilies*, and several large vineries are heavily cropped with *Black Alicante*, *Gros Colman*, and other Grapes.

One of the most pleasant things about the vast and still growing establishment, which finds employment for a great number of men, is the evidence to be seen in many things of the care which Mr. Rochford takes in studying the comfort and well-being of his men, and the good understanding which apparently exists between employer and employee.

CHRYSANTHEMUMS AT MR. C. TURNER'S.

During the past few weeks the Chrysanthemum display at Mr. C. Turner's, Royal Nursery, has been open to the inspection of the public, many of whom have taken the opportunity of enjoying the floral treat provided. The display is concentrated in four large houses, and besides embracing those grown for the production of large blooms, it includes immense numbers of decorative bush plants, and those for affording quantities of cut blooms for supplying the large demand for white and coloured flowers at the Christmas season and later, for which there is a large and increasing demand. Among the best of the large Japanese flowers *Phœbus* was conspicuous among the yellows, and is undoubtedly one of the best exhibition varieties. *Modestum* is another fine incurving yellow seen in good form. T. Wilkins, a fine bronze coloured flower, was noted in fine condition; this variety has been seen in first rate condition this season in many an exhibition stand. Australian Gold, Beauty of Teignmouth, Graphic, Mrs. C. E. Shea, Mrs. Dr. Ward, Richard Dean, Rose Wynne, Niveum, H. L. Sunderbrück, and Mrs. A. Hartshorn, among many others were remarked in good condition, carrying large flowers. I also noted blooms of the old variety *Japonais* of exhibition size; it is not often seen now. Two remarkably dwarf growing varieties, carrying large flowers, were noted in *Souvenir d'une Petite Ami*, white, and *Comte F. Lurani*, striking rose-colour, the edge of the petals lined almost white. The old *Val d'Andorre* is grown in quantity as a dwarf decorative variety; also *Putney George* and *Cullingfordi*. Late-flowering Japanese are grown in large numbers for cut flowers, the favourite variety being *L. Canning*, which had just been disbudded, nice bushy plants, about 2½ feet high, carrying eight or ten good flower-buds, many of which will be fully open at their best about the end of the month of December. Others were *Princess Victoria*, *W. H. Lincoln*, and *Christmas Gold*.

Good incurved blooms of *C. H. Curtis*, *Globe d'Or*, *Ami Hoste*, *Barbaran*, and *Jardin des Plantes*, were noted among many others as being particularly fine. Other houses contain hundreds of plants of *Bouvardias* and *Tree Carnations* coming into flower, the first-named looking likely to furnish immense quantities of flowers. The principal varieties of *Bouvardias* grown are *Alfred Neuner*, *President Garfield*, *President Cleveland*, *Hogarth*, *Priony Beauty*, and a variety that originated here, named *intermedia*. It may be mentioned that the whole of the Chrysanthemums are in a very clean and healthy state, and the grower may be congratulated on their appearance and immunity from "rust" and all other diseases. H.

CONTINENTAL NOVELTIES.

M. LEMOINE, OF NANCY, OFFERS—

Deutzia corymbiflora.—A new shrub, found in Se-tshuen (China) by the Abbé Farges, and introduced into France by M. Maurice de Vilmorin. It is a plant with rather slender branches, the new stems erect, round, the bark lenticellate, internodes rather long; leaves large, almost sessile, or the petiole not more than a fifth of an inch long, oboval, lanceolate, pointed, very finely dentate, wrinkled on both surfaces, with very fine hairs above, the upper surface deep green, the lower clear green. The stems of the preceding year bear in every axil composite panicles, nearly corymbiform, each containing from fifteen to forty flowers. The pedicels are very short and very slender, the calyx cupuliform, clear green, bears five little dark green teeth. The five petals, well open, wide at the base, pointed at the tip, are fully spreading. The stamens, five large and five small, have a very wide winged filament on which the clear yellow anther is directly inserted; the three styles are very short, the height of the small stamens, and concealed by them. The filaments of the stamens form a close and firm column, persistent during the flowering. The appearance of the flowers is a little like that of *Solanum jasminoides*. The usual flowering season

is during the first fortnight in June; the shrub is then covered with a profusion of little snow-white flowers; the new stems often tipped in August and September by fresh blooms.

Deutzia Lemoinei compacta.—*Deutzia Lemoinei* is now established as an outdoor plant, and for forcing. This variety has the same origin, is much more dwarf, and tufted naturally; the flowers are the purest white, and nicely expanded; the spikes so numerous as to form a thicket of bloom. The plant altogether lighter, more elegant in blooming, is to be recommended for pot-culture and market uses.

Diervilla (Weigela) Middendorffiana.—*Weigela* with large yellow flowers is not a novelty, as it is described and figured with a coloured plate in the *Flore de Van Houtte* in 1856, but it has been almost entirely lost in Western European cultivation. The

FIG. 107.—SALPIGLOSSIS VARIABILIS SUPERBISSIMA "EMPEROR."

species appears to come from the cold or elevated districts of Mongolia or Siberia, whence it was brought to us through Russian horticulturists. Its habit and foliage resemble those of *D. rosea*; the flowers, axillary, grouped in three or four, are as large as those of the preceding species, and of a beautiful saffron-yellow colour, dotted in different shades, which graduate according to the extent of expansion of the corolla.

Hypericum galioides.—A woody species from North America, forming a little hardy thicket furnished with long linear leaves, grouped like those of *Galium*, and very decorative; the small flowers, which are clear yellow, with very numerous stamens, and arranged in successive rows, cover the shrub profusely during all July and August.

Philadelphus Falconeri.—This plant, the origin of which is uncertain, must have been introduced from China or Japan to the United States. It is a hardy shrub, growing nearly 10 feet high, with fine and slender branches, internodes long, leaves rather small, lanceolate, hardly dentate; flowers in small panicles

at the tip of the axillary branches, formed of four pointed, pure white petals, and rather resembling those of *Clematis montana*. We received this shrub from Professor Sargent.

MR. F. C. HEINEMANN, ERFURT.

Salpiglossis variabilis superbissima "Emperor."—This variety of *Salpiglossis variabilis*, for the name of which we happily are not responsible, is an introduction of the Erfurt firm of Mr. F. C. Heinemann. The plant is distinct in habit, as well as in the flowers; it forms only one stem, which often grows as thick as one's finger, bearing on its end a bouquet of flowers veined with gold, and larger than those of the *S. grandiflora* type. The edge of the flower, as will be seen from the illustration (fig. 107), is not so deeply incurved as in this variety, which gives it a more rounded appearance.

COLONIAL NOTES.

ST. VINCENT.

"At St. Vincent, Coffee and spices are being grown. The value of the spices, chiefly Nutmegs and Mace, exported in 1895, was £1812.

"In the development of these and other industries (including that of sugar), valuable services have been rendered to the island by the botanic station established in the neighbourhood of Kingstown. The plants distributed have included 34,335 Arabian Coffee, 3164 of Liberian Coffee, 5343 Cacao, 1183 Nutmeg, 2390 new and improved Sugar-canes, and 1108 Limes. The total plants distributed have amounted to 53,224. Large stocks of plants are still available for distribution. The Curator visits various parts of the island whenever his duties allow, and gives assistance to all engaged in agricultural pursuits. Bulletins with agricultural information are issued, and gardeners are trained in horticultural methods. The present curator, Mr. Henry Powell, is devoted to his duties, and his services are widely appreciated amongst all classes of the community. If the stringent measures of economy necessitated by the poverty of the colony are carried out, it is feared the usefulness of the station will be destroyed." *Report of West Indies Commission.*

DOMINICA.

"The botanic station at Dominica was started in 1890, in a charming spot immediately behind the town of Roseau. Mr. C. A. Barber, late Superintendent of Agriculture in the Leeward Islands, states in a recent report:—"The founding of the botanic station in Dominica will probably, in future years, be referred to as one of the greatest strides in the progress of that island during the present period." There are large nurseries of economic plants and experimental plots for Cacao, Coffee, Kola, Rubber-trees, spices, and fibre-plants. The station, which may be regarded as one of the most successful in the West Indies, has distributed 165,000 economic plants during the last six years, or an average of 29,000 per annum. The present curator, Mr. Joseph Jones, is described as having rendered 'great services universally acknowledged by the planters of the island.' The cost of the station in 1896 was £400, while the net receipts from the sale of plants were £99. It is proposed in the 'Additional Note' at the end of this report, to extend the work of this station, employ agricultural instructors, and establish an industrial school in connection with it." *Report of West Indies Commission.*

MONTSERRAT.

"A botanic station, with a gardener in charge, was started at Montserrat in 1893, on a small plot of land to the South-west of the town of Plymouth. The space available was utilised for the cultivation of a selected number of economic plants: large numbers of these were raised and distributed during the last six years. Amongst them were 8000 plants of Blue Mountain Coffee from Jamaica, 1800 Cacao, 2000 Nutmeg, Pine apple suckers, Grape Vines, 800 suckers of the Jamaica Banana, Liberian Coffee, Kola, &c. The gardener also gave information in regard to the cultivation and treatment of new plants. The principal recipients were estate proprietors, and not small cultivators. The latter had evidently not been induced to start new cultivations, as, owing to the absence of shipping facilities, there was no prospect of being able to find a market for the produce. Owing to the straitened circumstances of the island, the botanic station has now been abolished, and the services of the gardener diverted to other duties."

The work done at this station, with the limited means at its command, was of a distinctly promising character. It was the only organisation existing in the island for improving and extending the cultivation of industrial plants, and its abolition destroyed the hope of immediately benefiting the agricultural interests of the island." *Report of West Indies Commission.*

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Bush-fruit.—Brief lists of select varieties of Apples, Pears, Plums, Cherries, Peaches, and Nectarines, were given in the *Gardeners' Chronicle* for October 23, (p. 288). We supplement these lists by giving similar ones of Gooseberries, Currants, Raspberries, &c.

Gooseberries.—*Green*: Greengage, Green Hedgehog, Keepsake, and Rosebery; *Red*: Whinham's Industry (the earliest Gooseberry in cultivation) Crown Bob, Ironmonger, Lancashire Lad, Red Champagne, Rifleman, Warrington; *White*: Cheshire Lass, Whitesmith, and White Swan; *Yellow*: Golden Drop, Golden Lion, Yellow Champagne, and Yellow Ball.

Currants.—*Red*: Raby Castle, Knight's Early, Reine Victoria, Prince Albert, Fay's Prolific; *White*: White Dutch, White Transparent, and Shilling's Queen; *Black*: Baldwin's Champion (an immense cropper, the largest, sweetest, and best for market), Lee's Prolific, and Carter's Champion, an excellent variety, almost, if not quite, identical with Baldwin's Champion.

Raspberries.—Superlative, the largest and heaviest cropping Raspberry in cultivation, producing immense conical-shaped fruit of excellent quality. Next to this in point of size, cropping, and other good qualities, comes Hornet; Carter's Prolific, and Baumforth's Seedling, also first-rate varieties. The Antwerp and Magnum Bonum are good white varieties. Belle de Fontenay is the best autumn-bearing Raspberry that I am acquainted with.

Figs.—White Marsouilles, Brown Turkey, Castle Kennedy, and Brunswick are trustworthy varieties for out-door culture, and they come into bearing and ripen their fruit in the order in which the names appear. The trees should be planted against walls having a south aspect.

Winter Treatment of Figs.—The old-fashioned and erroneous way of treating Fig-trees during the winter and early-spring months, with a view to securing a crop of fruit the following summer and autumn, finds but few followers now-a-days. I refer to the practice of unnailling the branches on the approach of winter, and bundling them up together on either side the centre of each tree and half-way down the wall, securing them thereto with tarred string, and then covering the branches thus tied together with a good thickness of bracken, which was generally allowed to remain round the branches till the end of March or early in April, on the assumption that protection of the kind indicated was necessary to secure a crop of fruit the following year. This practice thwarted the object in view, by rendering the trees so treated somewhat tender, and at the same time causing them to push into growth before their proper time, and subjecting them to check by exposing them to spring frosts when the covering of Fern was taken off, with the consequent failure of crops. It is about twenty-three years since I first condemned the above-mentioned practice in the *Gardeners' Chronicle*, and recommended one which I have practised with very satisfactory results during the interval between 1871 to 1896—namely, to leave the branches of the Fig-trees undisturbed and unprotected during the winter and spring months—that is, to afford them no protection of any kind in southern and western counties in England, Wales, and Ireland, and the southern counties of Scotland. In exceptionally severe winters, following a wet autumn, the unripened terminal shoots will be cut up pretty much from the effects of frost; but this may not happen once in ten years; moreover, the trees thus cut back recover the following summer, and bear a fair crop of fruit as well—such at any rate is my experience.

Planting Fig-trees.—A space of from 15 to 20 feet should be allowed between the holes in planting Fig-trees in their permanent positions on walls, planting young Peach, Nectarine, or Apricot-trees temporarily between them. In planting young Fig-trees, the

holes should be made about 2 feet deep, and extend 2½ feet from the wall, and 1½ foot on either side the central position marked thereon for each tree. Break up the soil in bottom of the holes, and place therein a 6 inch layer of brickbats or clinkers, broken somewhat fine on the top, covering this with turves, grass-side down, or long litter, so as to ensure good drainage. And plant the trees in a mixture consisting of about four parts good sandy loam and one of old mortar-rubble, working this well in among and around the roots in planting, shortening straggling roots, and cutting-back damaged ones, before covering them with the compost indicated. The planting of all kinds of wall-trees may be done in the manner described above; and the sooner the work is done the better. If the border in front of the Fig-trees is manured for vegetables, it will be necessary frequently to lift the points of the roots to the surface; and in cases of gross development of shoots and loss of fruitfulness, partial transplanting will have to be resorted to, and a mixture of the materials given above substituted for the rich soil thrown out from among the roots. Apples and Pears being still in full leaf, will not be ready for lifting and sending away from fruit-tree nurseries much before December.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Manuring and Digging Land.—The manuring and digging of vacant plots of land may now begin, trenching it if that operation has not been done for three or four years, and bastard-trenching or plain digging one spit deep that which has been more recently trenched, and leaving the surface in all cases in a rough state, or ridging it. Ridging is always preferable with stiff clayey soils, and never does harm to medium ones; but it renders light, porous soils unduly dry, and not fitted for inducing seeds to germinate freely; and these light soils are really better flat-dug or trenched in late winter or spring. If wireworm be troublesome, spread gas-lime at the rate of 20 bushels per acre before digging; or dress the land with it after digging at the rate of 30 to 35 bushels, and leave it on the top till the spring, at which season it may be forked in. Still soils are, as a rule, benefited by trenching once in four years. If there is much undecayed vegetable matter in the soil, as will sometimes be the case in old gardens, unslaked lime should be incorporated with it, and in trenched soil some of it should be stirred into each layer of spits, no manure or other dressing being applied that year. For the benefit of those who may not have practised ridging and trenching, it may not be amiss to explain the process, simple though it be. After spreading the manure evenly over the ground, if the piece be of 15 to 20 yards wide, stretch the line down the middle of it, and cut a little furrow along it with the spade, then proceed to open a trench at whatever depth the land is to be trenched or dug, at the end of one half, and wheel the soil on to the alley close to where the last trench will be of the other half. This is a great saving in labour, and it is applicable to nearly all wide areas. The trenches may be 2 feet to 2½ feet wide. In the case of heavy soils the trenches should run north and south, in order that the sun may shine on both sides of the ridges, and there may be no wet furrows. Sometimes Potatoes are planted in the trenches after making the soil of fine tilth with the hoe, but the early crops of tubers should not be so planted, rather the land should first be levelled, and then planted with the tubers.

Early-forced Potatoes.—Where very early Potatoes are required, the sets should now be placed eye end uppermost in boxes of leaf-mould or cocoa-nut fibre refuse, and forced in gentle heat. Veitch's Early Ashleaf and Sharpe's Victor are general favourites for early forcing. Sutton's A1 is a first-class variety for quick returns and good quality, and should be given a trial by those who are unacquainted with it. Where ordinary dung-pits are used for forcing Potatoes, they should now be filled with fresh tree leaves, three parts consisting preferably of those of Oak or Beech, mixed with fresh stable-manure one part. Those who have no leaves to make use of, must employ stable-manure, which will require almost as much preparation as if it was going to be used in making Mushroom-beds. The heap of leaves and litter must remain till fermentation has taken place, and be turned twice or thrice afterwards, letting it ferment anew after each turning over. It will then be in a fit state for making up a Potato-bed. If a bed is built on the ground, it will have to be 5 feet high at the back, and 4 feet at the front, and a foot bigger all

round than the frame which is to be put on it. In all cases the materials must be put together compactly, and more straw must be used at the outsides of the free-standing bed than is recommended above, or it will not be kept together. When the heat has reached 75° to 80°, put into the pit or frame rich light soil to the depth of a foot, planting the sets when this mass of soil has got warm throughout. Hot-beds built on the ground should be surrounded with litter or straw-hurdles. Even if very early forcing be not practised, a large heap of tree-leaves and manure, prepared for use, will become necessary shortly for a variety of purposes.

FRUITS UNDER GLASS.

By F. HARRIS, late Gardener, Eastnor Castle, Leicestershire.

Strawberries.—The earliest plants standing on hot-beds consisting of tree-leaves, or in mild heat without these useful aids to forcing, will be thrusting up their flower-stalks, and in order to get the stalks as long and strong as possible at this season, when they are naturally slow of development, and grow in length but little, and nestle in the crowns, the plants must be removed to a light position in a forcing-house, where they can be afforded a day warmth of 60°, and by night of 50°. Nothing higher than this should be afforded for a week or ten days, and then there may be an increase of 1° or thereabouts, and so on till the maximum is reached, any undue hurrying being always followed by disaster. When the flowers begin to expand, the air should be rather dry than moist, which can be done by omitting to damp down, not by the use of a greater degree of artificial heat; and air must be admitted in moderate amount in favourable weather, and if it can be admitted night and day without causing draughts, or impinging on the plants direct, it will strengthen them. Artificial fertilisation must be practised with all the earlier batches, distributing the pollen by passing a rabbit's tail over the blooms in the middle hours of the day. Having obtained a fair set, thin the fruits as soon as it can be seen which are going to develop properly, leaving four or five on a plant, later successions carrying more. Introduce successional plants at fortnightly intervals, regulating the number and the interval by the demand, fifty plants being regarded as an average number of plants to place in heat at one time. Ascertain the state of the stock of plants as regards moisture at the roots if they are under glass, dryness being very prejudicial to them. If frames are not available for the protection of the plants, some other kind of covering should be at hand, to use in the event of heavy rain or snow falling, or severe frost occurring. The pots should in any case be plunged in coal ashes or tree leaves.

Tomatoes.—The plants for affording fruit should be divested of all lateral shoots and superfluous foliage, not however stripping the latter to an injurious extent, but thinning it out here and there. Tomatoes should be gathered when fully coloured, and the ripening carried out in a warm, dry house. To make sure of the flowers setting, pollination should be artificially carried out. Young plants raised from seed in the autumn for fruiting in the early spring, must be kept near to the glass in a warm pit or house, and wide apart, to avoid spindling. Each will require a neat stake to which to secure it, for should a stem be twisted or bent, the plant never does so well afterwards. Seeds may yet be sown of free-setting varieties, sowing thinly, and covering lightly, and standing the seed-pots on mild bottom-heat, and removing them when germination has taken place, to a shelf in the stove or other warm-house. When a few leaves are made, prick-off the seedlings into small pots.

Cucumbers.—From the present time till the middle of January is a bad interval of time for the Cucumber-plants, and every effort must be made to keep them clean, healthy, and progressing. Let the beds be afforded tepid-water; decaying leaves and deformed fruit removed, and the surface slightly stirred—if no roots are injured thereby. Top-dressings will also be required from time to time, which may consist of fresh horse-droppings alone, mixed with loam. Destroy aphids and thrips before they increase much. Use the syringe overhead very sparingly; and maintain a bottom-heat of 80°, and top-heat by day of 70° to 75°, and 65° at night. Damp the walls, paths, and borders once or twice a day. Do not allow fruits to remain on the Vine after they have become of useable size, and thus will the resources of the plants be husbanded to the uttermost.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maidenhead.

Deciduous Trees and Shrubs.—Any contemplated planting, transplanting, or alterations in shrubberies or elsewhere may now be carried out whilst open weather, which is favourable to operations of those kinds, continues. It may happen that the soil is in a dry state, especially in proximity to trees and shrubs, or on slopes, and application of water may be necessary a day or two before transplantation is begun. In the case of new plantations on heavy or very moist land, it may be that the drainage must be attended to first if the plants are to make satisfactory progress. It is always safest in woodland, or on lawns or in shrubberies, to put in drains at a depth of 3 to 4 feet, and 20 feet apart; and instead of using the common rain-pipe or tile, to fill in a V-shaped water-course with clean road metal, flints, granite, or brickbats, and use these to place an inch or two of hogget, or sycamore-wood, or sods 2 to 3 inches thick; even the outlet drain may be constructed in the same manner. Such drains will remain unchoked with tree and shrub roots, whereas drains of the other kind soon get choked and useless for the purpose they were put in. *Azalea pontica*, *A. mollis* are going to be planted, and peat of fair quality, consisting of the upper layer cut at about 6 inches thick, if possible, is obtainable at small cost, this may be used in a roughly broken-up condition, with or without an addition of coarse sand, as may be determined by the presence or absence of sand in the peat. Failing peat, light turfy man mixed with leaf-mould, sand, decayed manure should be employed. Plants that do not come under the category of peat-loving may be afforded new pasture-loam and charred earth and manure. Trees and shrubs should be chosen which fall in with the general effect, and are not incongruous in growth and colour with the surroundings; and if they are such as are beautifully coloured foliage in the autumn, so much the richer and pleasing will the garden or pleasure-ground look at that season. The hardy ones are among the prettiest of these, and where there is no lime in the staple, these should be freely planted. The common yellow and orange-flowered varieties grow quickly. Some of the Japanese *Acer* form interesting shrubs of moderate size, and are useful for planting in shrubberies, the finely cut foliage of various hues being very decorative. I may mention *A. palmatum* of a variety of shades of greyish green; *A. p. linearilobum* with long, narrow leaves, shoots of a reddish age; *A. sanguineum* with deep crimson-coloured foliage; *A. p. septemlobum* elegans that becomes a rich green early in the season, changing to a deep red shade at a later period; *A. p. atropurpureum* with foliage of a coppery-purple tint, a bright-coloured stem; and *A. ampelopsifolium* with foliage assuming the coloration of the Virginian Creeper. Stronger growing are *Acer platanoides*, the Norway Maple, of which there are several varieties which have beautiful autumn foliage. *Cassia japonica*, a hardy shrub growing 8 to 10 feet in height, and of a spreading habit of growth, produces long racemes of yellow flowers; *Eucryphia pinnatifolia* is another handsome plant with large white flowers that come in July and August. The early-flowering Almonds, the earliest among spring-flowering shrubs, should not be omitted; the crimson and rose double-flowered varieties of *Amygdalus persica* (Peach); *Calycanthus floridus*, or American Lilipies, with brownish-purple, fragrant flowers; *Lagunias* in variety, both the early-flowering *M. conspicua* and later *M. purpurea*; *M. Soulangiana*, *M. S. x Lennel*, *M. tripetala*, and *M. Thompsoniana*, to form a succession; *Cerasus* in variety, including the drooping-habited Bird-cherry, *C. Padus*; the Judas-tree, *Cercis siliquastrum*; white and yellow-flowered Brooms *Laburnum vulgare* *C. dami*, and others; *Liquidambar styraciflua*, the foliage of which assumes rich tints in the autumn; *Philadelphus coronarius*, *P. microphyllus*, and *P. radiiflorus*; *Prunus myrobala*, fl.-pl., and *P. laurardi*, with its handsome purple foliage, with *P. nioha*, all of which flower in the spring months; thus *Cotinus*, which dies off of bright golden tint; *ambucus nigra aurea*, with its yellow variegated foliage, is handsome throughout the summer months, and are several others of the same species. *Spiræa* (shrubby) offer great variety, in which the following are desirable:—*S. arifolia* (one of the handsomest), *S. Bumalda*, *S. Douglasii*, *S. Lindleyana*, *S. prunifolia*, fl.-pl., a low shrub, whose leaves are very handsome in their autumn tints; *Crataegus* of the Hawthorn section in variety of colour, both single and double-flowered; *Syringa* (Lilac), including *S. Josikea*, and

some of the newer varieties, as *Souvenir de L. Späth*, *Marie Legraye*, *Leon Simon*, and *Virginité*, not forgetting the floriferous Persian, *Lilacs*, the *Gueldres Rose*, *Viburnum Opulus*, *V. lantana*, *Deutzias* in variety, *Kolreuteria paniculata*, &c.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorset.

Aërides, Saccolabium, &c.—In the East Indian-house, such species as these, the warm-growing *Vandas* and *Rhynchosyris*, will need special attention, as many of them have almost ceased to grow. These evergreen epiphytes should be rested for a shorter space of time than deciduous species, although the greater length of time they are in an inactive state the stronger will be the new growth. For the present let the amount of water at the roots be gradually lessened, and it will be noticed that when the roots cease to grow in length, the tips gradually turn from green to white, the only indication that the season of rest has come. Only enough water should then be afforded as will keep the leaves fresh and green till the roots again begin to make growth. Sometimes these plants suffer from "spot" during the winter, and when this appears, let all the sphagnum-moss between the roots be removed, and the interstices filled up with clean crocks. By this method the plants may be kept sufficiently moist by pouring water through the crocks once or twice a week, and the danger of over-watering is got rid of. These plants are apt to lose their lowermost leaves in the winter, the cause of which is an excess of artificial heat in very cold weather, too much moisture in the air of the house, and drip. For several weeks past the terrestrial species, *Habenaria militaris*, *H. Susanæ*, *H. carnea* and its pure white variety, *nivosa*, have been in bloom; and now that the flowers are beginning to fade, the leaves and stems will soon turn brown, and if allowed to remain these will in time fall away naturally. The plants while in this stage should be placed near the roof, in order to get the new tubers ripened. Care must be taken to gradually withhold water when the leaves begin to change colour, and the stems have decayed; a little water may be afforded only when the surface-soil is dust-dry, by which means the tubers remain plump during the entire season of rest. It is not advisable to withhold water altogether, as excess of dryness will cause the tubers to shrivel, and make weakly growth in the spring.

The Cattleya-house.—Plants of *Odontoglossum citreum* having ceased to grow, the water afforded may be gradually diminished and discontinued by the middle of next month, and keep the plants near the light. *O. Reichenheimi*, having also ceased to grow, should be removed to the driest part of the cool-house, and be afforded water in sufficient quantity to keep the roots and pseudo-bulbs plump. Plants of *Miltonia vexillaria*, now in full growth, should also be examined occasionally, slitting the sheath around the leading breaks, so that the young roots may escape and enter the compost. The slitting should be carefully done in several places, and the outer covering pulled off in small pieces. At this period, too, the young leaves stick to each other, and must be separated carefully. The tips of the young leaves frequently turn of a brown colour and damp off at this season; and to avoid this, keep the plants drier at the root for a few days, and do not moisten the sides of the pots. *M. Rozii* and *M. Phalaenopsis* are species that make their growth at this season; place them, therefore, in the warmest part of the house, and let them have abundant root-moisture. Plants of *Odontoglossum pulchellum* will now have made up the new pseudo-bulbs, and as it is a plant apt to lose its roots if the compost be kept very moist, put the plants in a light position in the cool house. The same remarks as regards watering applies to the rare *O. Londeboroughianum*, which should be placed in a rather dry part of the Mexican or intermediate house.

THE APIARY.

By EXPERT.

Long Hives v. Tiering-up.—Why do not those who work for extracted honey use a long hive, holding the same number of frames that they wish to use in one story, instead of tiering-up several hives one on top of the other, as is advised in our bee papers, and quite generally practised? This brings to my mind what happened years ago, and as it will serve to answer the above, I will give it here. Some twenty or twenty-five years ago, Mr. D. L. Adair, of Kentucky, was quite

a prominent bee-keeper and writer for our bee papers. He used and advocated a long hive to be used on the principle of spreading frames out horizontally instead of tiering one hive above the other, claiming that thereby a colony of bees could be kept in a normal condition, and while in that condition, no swarming would occur. This he termed the long Adair hive. Being always ready to test all new ideas, I made two hives, each 4 feet long, during the next winter. One of these I worked and extracted, and the other for comb honey on the Adair plans. The ones worked for comb honey swarmed, either because the idea was faulty or because I did not know how to fully manage such a hive, or for both reasons; so after repeated trials to keep them at work in the 4-foot hive, I let them have their own way, when they had swarmed after being returned the fourth time. The one worked for extracted honey did splendidly, but another worked on the tiering-up plan did nearly or quite as well, and by practical knowledge I learned that I could work a two or three-storey hive much more easily than I could this long one. To take the frames out, the person's back must be bent just enough to make it the hardest kind of work; and the bees which were shaken off the combs, would crawl all over the sides of top of the hive in such numbers as to make it almost impossible to close it again without taking up much valuable time. With the two-storey hive the bees can be shaken on to the top of the frames in the lower hive, with but very few taking wing, when the bulk of them will crawl below till the hive is closed, and the operator can stand erect, or nearly so, while doing the work. But the worst thing about it was that I lost both colonies during the next winter, and during every succeeding winter that I tried to winter bees in them. So far as I could see, they were prepared to pass the winter, as well as any of the other hives, which came through the winter in good condition. I used these hives for honey making during several years, putting colonies from other hives into them in the spring as often as those in them died, but with no better success than at first; and finally becoming disgusted with them, I tore them to pieces, and made the materials into other hives. I know of nothing better than the ordinary hives two or three storeys high, according to the populousness of the colony which is being worked.

PLANTS UNDER GLASS.

By G. H. MARCOCK, Gardener, Luton Hoe Park, Luton.

The Stove.—Now that winter days with greatly reduced sunlight have arrived, the gardener should rearrange the plants, placing those that are not sight and are at rest in the less sunny and inconspicuous places in the house, and those plants with persistent foliage and abundant flowers in the more prominent parts of the house. It is always difficult at this season to avoid crowding the plants, but this should be avoided as much as possible, affording the plants as a whole all the sunlight practicable. Plants of *Allamanda*, *Clerodendron Balfourianum*, *Dipladenia*, *Stephanotis*, *Cissus discolor*, &c., trained on overhead wires and rods should be taken down and the shoots twined around three stakes, keeping the soil dry, previously to pruning them at the end of the present month. Doing this will economise space, and afford such plants as *Codiaeums*, *Ixoras*, and others, room for display, especially if these can be elevated here and there on flower-pots or other contrivances. These plants should be rested, turning them round twice a week. *Gloriosa superba* is another plant that may be similarly dealt with; and *Pandanus Veitchii* will also be the better for having less water afforded. Any *Pandanus* that have grown too large for ordinary purposes should be thrown away; or, after removing all the leaves, the old stem may be reserved for propagation purposes in the early spring. *Medinella magnifica* may also be kept drier at the root, but not so much so as to cause the wood to shrivel. This is a glorious plant, and worth having in every place where large specimen-plants are liked.

Caladiums.—The tubers must be wintered in the stove, or in stove temperature, either keeping them in the pots in which they grew, or turning them out into silver-sand. A few of the earlier-rested tubers, of *C. agryites* may now be shaken out, and placed in 60's, standing them on a side stage; but the strong-growing varieties should be kept in their winter quarters till the turn of the year. Let the lights of the house be cleaned of conserve and dirt, stopping all faulty places in the putty, and making it, as far as possible, weather-proof, cleaning stages, &c., and lime-washing the brick-work. For the present a temperature of 65° by night and 70° by day will suffice.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, Nov. 23	Royal Horticultural Society's Committee.
SALES.	
MONDAY, Nov. 22	Bulbs, at Protheroe & Morris' Rooms.
TUESDAY, Nov. 23	Bulbs, Plants and Roses, at Protheroe & Morris' Rooms. Sale of the Glass Erections, Plants, Fruit Trees, &c. at The Gardens, Stone Grove, Edgware, by Protheroe & Morris.
WEDNESDAY, Nov. 24	Bulbs, at Protheroe & Morris' Rooms. Sale of Specimen Shrubs and Conifers, at the Feltham Nurseries, Feltham, by Messrs. Protheroe & Morris.
THURSDAY, Nov. 25	Plants and Roses, at Protheroe & Morris' Rooms.
FRIDAY, Nov. 26	Bulbs, at Protheroe & Morris' Rooms. Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—41° 5'.

ACTUAL TEMPERATURES:—

LONDON.—November 17: Max., 57°; Min., 49°.

PROVINCES.—November 17 (6 P.M.): Max., 56°, Scilly, York; Min., 47°, Stornoway.

Weather generally mild, dull, and damp.

A FONDNESS for dabbling in the Water-Plants. water seems to be a general characteristic of the human race, especially in its youthful stages. As age increases, the "dabbling" is replaced by admiration and curiosity, and ultimately often by study of the water and of the creatures in it. Certainly, for many of us, there is no more attractive part of the garden than the lake, or the pond. Even the backyard may be furnished with its tub, and that tub made resplendent with the lovely hues of hardy Water-lilies and yellow Villarsia, with purple *Sarracenia* as an edging. We write of what we have seen and known both in the City of London and at the West End! A book treating on the formation and management of such a "garden," or on the utilisation of humbler opportunities, is therefore—has been rather—a desideratum. The want has been supplied in large measure by the elegant volume before us.* It is not given to everyone to be able to grow the *Victoria* in the open air in a heated pond, still less to accommodate its noble foliage and stately flower under glass. But hardy Water-lilies, including many other "aquatics," may be grown by those whose means and opportunities are but scanty. The introduction of the beautiful series of hardy Water-lilies by M. MARLIAC, has given an impetus to the cultivation of these plants, which not even the cult of Roses, Orchids, and Chrysanthemums can quench, and for those who have the command of waste-steam, the possibilities are greater still.

In the present volume, the author gives instructions as to the formation and maintenance of ponds and lakes, and has some judicious observations on the planting of the margins of the pond or lake. These are too often left formal and rigid; or, when something more natural and appropriate is attempted, then the tendency is to indulge in curvatures too numerous and too abrupt, meaningless "wiggle-

waggles," which irritate rather than please, and are destructive of all sense of grace or restfulness.

Beauty of appropriateness here as elsewhere is a matter of cardinal importance. We have in mind two town-gardens, both placed in the midst of formal architectural surroundings, the ornamental water in the centre in each case, encircled by or associated with groups of plants. In the one case, the plants are such as possess bold, stately foliage, such as *Musa Ensete*, *Arundo Donax*, Palms, *Aralias*, *Phormiums*, *Agaves*, *Cannas*, *Paulownias* kept cut back, *Colocasias*, &c.; in the other, there are the Sedges, the elegant grasses, the Bur-reeds, the giant Docks, the *Osmunda*, the Yellow-flag, and other plants we are so delighted to meet along the margins of a stream, or in a dell in the midst of the woods, but which look weedy and out of place in a town-square. Some of the plates in this volume afford illustrations of our meaning, whilst *Erianthus*, *Eulalia*, *Papyrus*, and ornamental grasses are fully in harmony with the arborescent vegetation around, the foliage of the *Musa Ensete* seems out of place. Compare, for instance, the plate at p. 38, showing a piece of water edged with *Typha* and ornamental grasses, with that on p. 42, where the harmonious nature of the margin is broken up by the intrusive foliage of the *Musa Ensete*. So, too, the plate at p. 50, shows the formal leaves of the *Victoria* associated with native N. American plants, such as *Golden Rod*, *Achillea*, &c., when *Musas* and "sub-tropicals" would be more in place. But these are matters of taste in which there is room for very wide differences of opinion.

Details concerning the method and time of planting are given, as well as hints on hybridising and propagation.

A descriptive list of the species and varieties of *Nymphaea* and *Nelumbium* is given, with cultural memoranda suitable for those grown in the open or under glass. A similar enumeration is furnished of the miscellaneous aquatic plants, Ferns, hardy perennials, &c., which may be grown in association with or separate from the true Water-lilies.

The book is plentifully illustrated with photographs in which the contrasts of light and shadow are sometimes crude and abrupt, but which are characteristic and really illustrative of the text. Mr. LEONARD BARRON is responsible for the editing of the manuscript and for its supervision whilst passing through the press. He has done his part well, but he would have done it better had he given us an index as well as the table of contents. We strongly recommend those who are interested in this charming phase of gardening, to become the possessors of this book as the practical experience of the author is a guarantee for the excellence of his teaching.

BEGONIA MRS. W. B. HARTLAND.—The fine variety of tuberous-rooted *Begonia* delineated in fig. 108, p. 367, was raised by Mr. W. BAYLOR HARTLAND, nurseryman, at Ard Cairn and Patrick Street, Cork, and is named after his wife. The flowers are pure white, double, and held erect on stout stalks; and the plant is free-blooming, well suited therefore for bedding, and equally suited for cultivation in pots for conservatory decoration. We are indebted to Mr. HARTLAND'S kindness for the use of the woodcut.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral Meeting will be held on Tuesday, November 23, in the Drill Hall, James Street, Westminster, 1 to 4 P.M. At 3 o'clock a lecture on "Horticultural Exhibitions, Schedules, &c.," will be given by Mr. JOHN WRIGHT, V.M.H.

SCOTTISH HORTICULTURAL SOCIETY.—The struggle which took place in the Waverley Market, Edinburgh, on Thursday last, was an exciting one, the money prizes in some of the principal classes being of exceptional value. In another column of this issue we publish a telegraphic account of the principal features of the exhibition, which, in most respects appears to have been a very successful one. See p. 375.

THE NEW FLORA BRITANNICA.—In preparing the catalogue of the Lindley Library, this book was lighted on. It is noteworthy as not being entered in *Pritzel's Icones*. In the *Thesaurus*, indeed, it is included under "EDWARDS" with the title "The New Botanic Garden," but in the *Icones*, so far as we can find, it is not cited. This is the more remarkable, as the engravings seem to be excellent and the text trustworthy. It is a book which the plant lover will treasure. Its title runs as follows:—

THE NEW
FLORA BRITANNICA,
ILLUSTRATED WITH
ONE HUNDRED AND THIRTY-THREE
PLANTS.
Engraved by Sanson,
FROM THE ORIGINAL PICTURES,
AND
Coloured with the Greatest Exactness,
FROM
Drawings by Sydenham Edwards.
IN TWO VOLUMES.
VOL. I.
London: Printed for JOHN STODOLSKY, Piccadilly,
by T. BENSLEY, Bolt Court, Fleet Street.
1812.

BAILLIE MEMORIAL FUND.—The Duke of WESTMINSTER as President, has issued an appeal to Mr. BAILLIE'S friends for the purpose of instituting a permanent memorial of Mr. BAILLIE'S services, and in promoting the education and advancement of the large family of children he has left behind.

MR. WALTER SIEHE, the eastern traveller, to whom European gardeners already owe so much for many plants of new introduction, has returned to Mersina from the expedition he made this year to the Cilician Taurus and Cappadocia. His collections of new species, and of such as are valuable to horticulture, are more important than they have been in previous years. Mr. SIEHE now intends to cultivate the plants he has brought home in a garden at Mersina, specially devoted to them, and will then be able to supply well-established specimens whose growth may be depended upon. In this "hortus orientalis," as Mr. SIEHE calls it, he has already a large number of Alpine plants from the Cilician Taurus, besides about 10,000 examples of *Asphodelineae* of different species, such as *A. taurica*, *A. Balansea*, *A. imperialis*, n. sp., *A. Dammeri*, n. sp., *A. Basili*, n. sp., and others; and about 10,000 plants of *Galanthus cilicicus*, Baker. He has also planted large quantities of *Iris persica*, *I. Funonia*, *Colchicum cilicicum*, *C. bulbocodioides*, *Eranthis cilicicus*, *Eremurus caucasicus*, *Muscari alpinum*, *Bellevalia Heldreichii*, *Tulipa pulchella*, *Fritillaria Bornmülleri*, and many more.

MANUSCRIPTS OF GILBERT WHITE.—On April 26, 1895, Messrs. SOOTHEY, WILKINSON & HODGE sold by auction the author's original autograph MS. of GILBERT WHITE'S famous work on the *Natural History of Selborne* for the sum of £294. The same auctioneers will offer for sale on Nov. 25 a still more interesting batch of MSS. of the same author, and of the same work. These MSS. are the original letters which were sent by post by GILBERT WHITE to THOMAS PENNANT between August 10, 1767, and July 8, 1773. These letters were returned to GILBERT WHITE when he first conceived the idea of writing his famous natural history, and from them was drawn up the autograph MS. sold in 1895. The letters are all holograph but four, which are in the hand of an amanuensis, signed by GILBERT WHITE, and all but three occupy four pages folio. They are additionally interesting and valuable from the

* The Water-Garden. . . . By William Tricker.
New York: A. T. Delamare.)

fact that many of the details recorded in them were altered, omitted, or augmented in the published work. They passed after the writer's death into the

never been out of the possession of the family. The second lot of the GILBERT WHITE MSS. is *A Garden Kalendar*, dating from 1751 to 1767. It is the

form of a consecutive diary, recording the writer's almost daily operations on his own land, and notes of the results of experiments tried by him in forcing

FIG. 103.—TUBEROUS-ROOTED BEGONIA "MRS. W. B. HARTLAND." (SEE P. 366.)

possession of his brother BENJAMIN, who was a bookseller and publisher in Fleet Street, and who issued the first edition of the *Natural History*, and they have

author's holograph manuscript, and occupies 424 pages. This has never been published, excepting the portion May 1 to November 16, 1759; it is in the

and hothouse work. This MS. also has been continuously in the possession of the WHITE family, and is very little known. *Times*.

CHRYSANTHEMUM SHOWS are evidently extremely popular with the sight-seeing public. At Birmingham (on the authority of Mr. HUGHES, the Hon. Secretary), as many as 32,558 persons were admitted to the show, and over £600 was taken in cash at the doors. Our report of this exhibition, which was squeezed out of last week's issue, appears on p. 371.

THE MILDNESS OF THE SEASON.—Further evidences of the exceptional character of the present autumn, continue to reach us from many parts of the country. In one case Mr. R. H. BATH, of Wisbech, sends us sprays of fruits from Raspberry, Baumforth's Seedling. They are abundant, and certainly very remarkable.

REMEDY FOR DAMP FEET.—All who possess a garden—all amateurs, professional gardeners, and dwellers in country districts, realise the importance to health of keeping the feet dry and warm, which with the best-made boots and shoes is only possible in snowy and very wet weather when the soles and uppers are coated with dubbing. One of the best of dubbings we are acquainted with is undoubtedly "Gishurstine," a preparation sold by Price's Patent Candle Company, Ltd., Belmont Works, Battersea, S.W., and made, we believe, from a recipe of the well-known horticulturist, Mr. G. F. WILSON of Weybridge, the inventor of "Gishurst's Soap," itself another boon to gardeners and horticulturists generally.

RATING.—An important case in which a nurseryman has succeeded in gaining an abatement of his assessment has been determined at the West Kent Quarter Sessions. The justices, however, have agreed to state a case for the opinion of the High Court as to whether or not market and nursery gardens with glasshouses are entitled to receive the allowance of 50 per cent. off the rates in accordance with the provisions of the Agricultural Rates Act, 1896. The case is reported in the *Estates Gazette*, and we shall publish a fuller report next week.

GRAPES FOR MAIDSTONE.—In view of the fearful calamity which has overtaken our county town, I am endeavouring (says Mr. Wright) to arrange for a supply of Grapes for the sufferers. Nearly 2000 cases of typhoid fever have been recorded, and the distress is terrible. The struggle towards convalescence after attacks of this fever is always a long and weary one. The MAYOR tells me that Grapes are needed, and any one having some to spare, if only a bunch or two, would be performing a good act by sending them. Boxes sent to the MAYOR, marked "Maidstone Grape Fund," will be forwarded to the proper quarter, and both railways, S.E.R. and L.C.D.R., deliver such gifts free. I would gladly send printed labels to any one on the receipt of a post-card. I may add that kind promises of assistance have already been made by several well-known horticulturists, notably Mr. Chapman, gardener to Capt. Halford, Westonbirt; Mr. W. H. Divers, Mr. J. Hudson, Mr. Martin, gardener to Lord Leigh; Mr. W. Taylor, gardener to C. Bayes, Esq., Forest Hill; Mr. Summers, gardener to Lord Scarborough; and "A Friend." Others will be gratefully received. W. P. Wright, Willesborough, Ashford, Kent. [The greatest care must be taken that the patient does not swallow any of the seeds, or even the skins. Ed.]

"THE AMATEUR'S FLOWER GARDEN," by SHIRLEY HIBBERD; new edition, revised by T. W. SANDERS (W. H. & L. COLLINGRIDGE, Aldersgate Street, E.C.). The practical utility of this book has been proved by the long time that it has enjoyed public favour. It is not so technical as to scare the ignorant, nor so simple as to offend them. It is a concise epitome of decorative plants, and directions for cultivating them, both in and out-of-doors. The numerous illustrations are an additional attraction. The volume now before us has been brought up-to-date, and revised; and though it is difficult for one writer to thoroughly enter into the spirit of another, all must agree that in horticultural matters it is

especially necessary to keep up with the times. Those who knew and liked the old edition will, therefore, welcome this modern one.

"GLIMPSES INTO PLANT-LIFE," by Mrs. BRIGHTWEN (T. FISHER UNWIN, Paternoster Square). The sub-title to this book is *An easy Guide to the Study of Botany*, and it might well be thought at first that there are already countless volumes of a similar scope and nature. But Mrs. BRIGHTWEN has the advantages over many of her rivals of being truly in love with her subject, and able to deal with it in an attractive manner. Her easy pleasant style of writing must be familiar to many of our readers who are acquainted with former books from her pen. The present volume is partly composed of articles which have already appeared in *The Girl's Own Paper*, and, in our opinion, the author has hit the happy medium, and is neither so technical as to bewilder, nor so simple as to irritate her young readers. Her subject-matter is further elucidated by illustrations by herself and by THEO. CARRERAS, and is arranged in chapters dealing with the following topics:—"Adaptation, Roots, Tree stems, Leaves, Buds, Flowers, Pollination, Fertilisation, Fruit, Dispersion of Fruits and Seeds, Germination, Physiology of Plants, Insectivorous Plants, and Habit of Growth in Plants." Mrs. BRIGHTWEN's botanical knowledge having been gleaned from the highest authorities, leaves no doubt as to the reliability of her information, which will, as here presented, not merely please but interest her readers, and lead them on to more ambitious works for the study of which she endeavours to prepare them.

BERMUDA LILY DISEASE.—Mr. ALBERT F. WOODS contributes a paper on the "Bermuda Lily Disease," as a preliminary report of investigations undertaken for the United States Department of Agriculture, and which forms Bulletin No. 14 of the Division of Vegetable Physiology and Pathology. In his summary he says that:—1. The Lily disease is characterised by the spotting and distortion of the leaves and flowers, and usually the stunting of the plant. 2. The disease is quite serious on *Lilium longiflorum* and *L. Harrisii*, and also attacks *L. auratum* and *L. caudatum*. It is very prevalent in Bermuda; and in the United States, where the bulbs are forced, it destroys from 20 to 60 per cent. of the crop. It also doubtless occurs in Japan, France, and the Netherlands. 3. There are many theories as to the cause of the Lily disease, the principal ones being worn-out soil, premature removal of flowers and flower-stems, premature harvesting of the bulbs, carelessness in the selection of stock for propagating purposes, bad treatment during forcing, and the work of insects. 4. The work done shows that the disease is due to a combination of causes. In the first place the bulbs have become weakened through improper selection and improper propagation, and this weakening is further increased by the attacks of mites and certain fungi and bacteria. Bulbs which have been weakened in this way might regain their strength if the mites and fungi could be kept down, but those which are naturally weak cannot be made strong. During the time plants are being forced, they may also be weakened by over-watering, and consequent asphyxiation of the roots, or by allowing the roots to become too dry, and then over-watering. The foliage of such plants may be free from spots and distortions, but usually the leaves are badly diseased. 5. The spotting and distortion of the foliage is often due to the direct attacks of several genera and species of aphides, and of the young of the bulb-mite, to the injection of water into the young leaves in watering or syringing, and to the presence of water between the young leaves of plants having soft foliage. The injuries from the attacks of organisms are always more severe on the susceptible or naturally-weakened bulbs. 6. The disease cannot be cured, or even prevented, by adopting any single course of treatment. The fact that the bulbs have become more or less weakened by improper cultivation, selection, and propagation, shows the importance of adopting rigid measures to improve the stock. Only the strong and vigorous plants should be used for propagation. Crop-rotation

should be practised, in order to prevent the increase of mites and injurious fungi. Leave the stems on the bulbs until ripe, and in all cases avoid premature digging. The florist who forces the bulbs should exercise care in planting. Throw out all injured bulbs, and plant in well-drained, well-aerated soil. Endeavour to keep down aphides and mites from the start, and exercise care in watering and ventilating. Avoid feeding with solutions of horse, cow, and sheep manures, and use chemical fertilisers instead."

PUBLICATIONS RECEIVED.—*The Carnation Manual*, edited and issued by the National Carnation and Picotee Society (southern section) (CASSELL & Co., London, Paris, and Melbourne). A new edition of a work which should prove valuable both to the professional and amateur grower. "In it will be found papers from some of the most successful growers of the day, detailing the methods pursued by them, from the first impregnation of the seed to the final staging of the flowers upon the exhibition-tables." Needless to say, the present edition is brought up to date.—*Practical Hints on the Culture of Cacti*, by H. G. BOURNE. This is No. 4 of BROS & SON'S (Salisbury Court, E.C.) "Handy Series of fruits, flowers, and vegetables," and well worth perusal by all who have a fancy for Cacti. It is illustrated, and costs only 2d.—*British Astronomical Weather Almanack and Chart*. This is, we understand, the eighth annual issue of this little book by Mr. B. G. JENKINS. The weather forecasts included time only will test; but there is also plenty of miscellaneous information given.—*Random Shots at Birds and Men*, by "Jim Crow" (Roxburghe Press, 3, Victoria Street, Westminster). A humorous account of some birds and their characters, as compared with those of human beings.—*Dictionnaire Pratique d'Horticulture*. The sixty-fourth livraison of this work is now ready, and completes the fourth volume, the title-pages and reference-tables for which are included in this issue.—*Orchidées et Fougères Rustiques sous le Climat de Genève*. This is an illustrated catalogue compiled by M. H. CORREVOX, and issued from the Jardin Alpin d'Acclimatation, Geneva.—*Liste des Plantes de Montagnes et Plantes Vivaces and Liste Supplémentaire des Plantes Alpines*. These two publications are of a similar character to the last one mentioned, and are also written by and obtainable from M. H. CORREVOX.—*Botanisches Centralblatt*, No. 44.—*General Index*, from vol. i. to lx., edited by Dr. F. SCHAUMBURG, No. 1.

THE WEEPING SPRUCE.

Of all our common Conifers, the Spruce, *Picea excelsa*, is most prolific in variations. Some of these are of extraordinary character, some elegant, others ugly. Of pendulous varieties there are several, but none more remarkable than the one figured in our illustration at fig. 109, from a photograph kindly forwarded to us by Mr. A. D. Webster, the Superintendent of Greenwich Park. The tree, which measures 30 feet in height, is growing at Ide Hill, Sevenoaks, Kent.

HOME CORRESPONDENCE.

THE LINDLEY MEDAL.—Although I did not get the Lindley Medal, it was certainly intended to give me one for two grand examples of *Odontoglossum grande*, which I call *giganteum*, and which were entered in the Royal Horticultural Society's records. I was not so particular in those days, else I would have had a correct measurement taken of the flowers, and it would have been useful now for reference. It is quite thirty years ago since I sent up from Meadow Bank to Mr. A. F. Barron two examples, both with branched panicles of extraordinary sized flowers, half as big again as the best we see now, for one of the fortnightly meetings, held then in the Kensington corridors. The one panicle had sixteen flowers, and the other fifteen flowers, and the substance, the ground-colour, and the blotching were such as had never been seen before nor since up to this day. The Council sitting at the time were unanimous in expressing that such a marked example of cultural development was worthy of the coveted "Lindley Medal." Mr. Barron has

times since told me that no such example of culture had ever been submitted in London, must have been an oversight on the part of the Council to pass it by. I was striving at the time for the coveted Bateman Challenge Gold Medal, and to the grower and exhibitor who should in successive years total up the highest number of marks. It was open to all comers, and foreign, barring the winner of the only

Chron. in 1869, p. 447. But it has not all been plain sailing with me. About twenty years ago, the Council for the awarding of the Neil Prize in Edinburgh, which every three years selects a most distinguished horticulturist, dividing the honours between a botanist of distinction, the one three years, and a gardener who has distinguished himself the alternate three years. I lost it by the casting vote of the chairman. It was awarded to my old and

generally recognised, both at home and abroad, as the standing Orchid collection in the whole country. My distinguished friend, the late Hugh Low, did not, when I was in his nurseries, grow a single Orchid. His son sent from Borneo many plants, but they were generally sold in Stevens' Rooms; and not till after I had gone to Meadow Bank, did the firm grow these plants—and now what a grand lot they are passing year after year through business channels! This is a series of "grumbles," and I would not have been drawn into it, but for the discussion of the Lindley Medal, which I think, ought not to be lost among horticultural honours. James Anderson, Wallace Avenue, Manchester.

PRIVATE CHRYSANTHEMUM SHOWS.—There are certain gentlemen in the county of Surrey who generously and thoughtfully throw open their private Chrysanthemum displays to the public on certain Sundays in November. Amongst these, and residing in the Cranleigh district, are Sir Richard Webster, M.P., the attorney-general, Sir Henry Doulton, Mr. Pandelli Ralli, Mr. W. Webb of Amhurst, Sir R. Carbutt, and others. The attendances reach about 500 at each place, the public coming with eagerness from long distances to see these gratuitous shows. One gardener, remarking to me on the general conduct of the visitors, said that—"formerly they came to admire, now they come to criticise." That is a tribute to the growing interest in Chrysanthemums and their culture which marks the age generally. In such rural districts as these mentioned, where there are few people having leisure, and many are busily engaged on week-days, the opportunity thus offered to persons otherwise debarred from seeing the flowers is regarded as a great boon. That it is so largely availed of, shows how widely it is appreciated. These generous and liberal-minded gentlemen are but doing in their respective localities what the London County Council do so admirably in their parks and gardens. It is also some recognition, doubtless, of the principle that property has its duties as well as its rights; and whilst amongst its rights may be the closing of beautiful parks and gardens absolutely against the public, happily, as seen in this case, there are some owners who think differently and act accordingly. A. D.

FROGMORE ALL-THE-YEAR-ROUND CUCUMBER.—The handsome fruits of this all too-long-named Cucumber, shown to the Fruit Committee at the Drill Hall on the 9th by Mr. O. Thomas, of the Royal Gardens, Frogmore, were of so taking an appearance, that some natural surprise was expressed that they received no award. But the committee, having some time since made it a condition that in future no awards should be made to new or presumably new Cucumbers until the varieties had been tried under cultivation at the Royal Horticultural Society's gardens at Chiswick, they were compelled to be consistent, and refrain in this case from making an award. Had any been made, a pretty hubbub would have been raised by other Cucumber growers and raisers, especially seeing that the fruits came from the Royal gardens. Any suggestion of unfairness would be unjust. Mr. Thomas generally places before the committee only first-rate things, and his success in obtaining awards is due to that circumstance alone. In this case the committee unanimously agreed that the fruits were beautiful ones, and, but for the conditions referred to, they would have obtained an award. As the variety is termed "All the Year Round," it seems but fitting that its merits as an "all-round" variety should be tested by asking to see samples in February. Still the variety, a crossed seedling from Rochford's famous variety, is, for market purposes, too smooth and pale [1]. A deep green colour is an essential, and even spines are favourably regarded by some persons. An authoritative statement on the part of the Council having now been made that it is impossible to carry out a satisfactory trial of Cucumbers at Chiswick, it has been resolved by the Fruit Committee to withdraw the conditions as to a trial there at the close of the year, and to deal with Cucumbers at the Drill Hall on their exhibited merits. A. D.

THE DUTIES OF A SUPERINTENDENT OF A CEMETERY.—A public body advertised in the *Gard. Chron.* for candidates for the appointment of superintendent. I made an application for a form and a summary of the duties required. These are as nearly as possible as follows:—Gardener, caretaker, cashier, accountant, supervisor of headstones; to clean and heat all chapels; to disinfect and clean mortuary,

FIG 109.—A WEEPING SPRUCE. (SEE P. 368.)

working on the same lines as in 1866-67. The was Mr. Veitch, and he had to stand back in a recent competition, when the writer obtained by a considerable majority of votes, the only other Bateman Medal ever offered. It was impossible to say when it was a question of the totalling of very fortnight, and it was a proud day for me. Mr. Bateman, at a full meeting of the Council, the Medal round my neck—a full report of the findings appeared in the columns of the *Gard.*

respected friend, the late Andrew Turnbull, of Bothwell Castle; the Chairman remarking that I was a young man, and could wait a little longer. That was a substantial prize, carrying with it a Silver Salver with a suitable inscription, and generally from £60 to £70 in cash. The happy day for me has not yet come, the Council evidently passing me over because I left gardening and went into business. It is fifty-two years since I left Hugh Low & Co.'s nurseries to enter upon the forming of what was

and receive all bodies; to attend all funerals, and act as sexton; to receive certificates, and attach the same to weekly returns; to attend upon the officiating clergymen for the purpose of filling up and signing a book giving all the particulars of a funeral; to attend at coroner's inquests, also at all committee meetings; and the supervision of grave-digging, and the grounds generally; and this all for the munificent sum of £80 yearly. If the salary had been £200 instead of hardly one, the requirements could not have been more onerous; and it shows unmistakably what a lamentable pass public gardening appointments have come to. *G. D. J.*

COST OF GROUND WORK.—A few days ago whilst in conversation with a gentleman about the excavating and removing of soil to make a lawn-tennis court, I found that he had accepted the figures in an old *Horticultural Directory* as a true and complete means of calculating the cost, and I think it is a pity that any book containing such an amount of good useful information should in any part of it have such erroneous figures. Those to which I more particularly apply these words are: No. 1. Excavating in common soils not exceeding one throw or 6 feet in depth per cubic yard, 6d. No. 2. Filling barrow and wheeling for the first 20 yards, 3d. No. 3. Wheeling every additional run of 20 yards beyond, 2d. The price No. 1 is not far wrong provided the workman can continue to remove the soil to the desired depth with the spade, but as it more frequently happens that after a depth of from 2 to 3 feet has been reached he has either to make use of the pick, or else a very much increased force with his foot, and therefore takes more time to loosen a given quantity, the 6d. cannot be accepted as a sufficient price to excavate a cubic yard of soil, which, I understand, weighs about 30 cwt. [Not so much. Ed.]; and from experience I know that men would rather dig and cast clay in the brick-yard at 6d. per cubic yard than run the risk of meeting with impediments in the removal of the soil to any depth where the subsoil is not easily tested. The price quoted (No. 2) for filling and wheeling 20 yards is such that I have never been able to find men who would do it for the money; and little wonder, for I have found that if a contract is made with three men to remove a given quantity, one of them who is most probably known amongst themselves as the best spademan usually digs and fills the barrows, the others dividing the distance to wheel between them, each being satisfied that in this way the labour is fairly divided; a common price for men to ask being 1s. per cubic yard for excavating and removing 20 yards, 1s. 6d. for 40 yards, and so on for every additional 20 yards which barrow runs. Calculating men's wages at 3s. 6d. per day, if three men must earn that sum at the price given in the *Horticultural Directory*, they would have to dig and remove a distance of 40 yards, no less a quantity than 11½ cubic yards, or about sixteen ordinary cart-loads; but it is seldom men can be met with willing to exert themselves sufficiently to accomplish such an amount of work for the money; and thus, in my opinion, the figures referred to are misleading. *Henry Hulce.*

SITUATIONS VACANT.—The above heading will, I have no doubt, attract the eye of a large number of readers of the *Gardeners' Chronicle*. My aim is not to catch the eye of the *employé*, but to attract the notice of the employers, especially of those who use the advertising columns to fill vacancies that occur in the various departments of their establishments. How frequently we see advertisements for gardeners and other *employés* finishing with the objectionable phrase, "state wages." Now, in my opinion, this is a very difficult point. Most men want as much in wage as they can obtain, and if gentlemen want a good practical man, they ought not to object to pay a good wage, such as would cause him to consider that he was settled, and make him take an interest in his employer's place and property. In "stating wages" when answering an advertisement, a person does not, in nineteen cases out of twenty, know what salary has previously been paid for the same duties, which everyone knows varies much; he naturally does not wish to ask less than has been paid, and at the same time he is afraid of losing the place by asking too much, for well he knows that many employers select the cheapest man, and think they can get a good experienced gardener or other servant for a small wage; for many good men are driven to accept what they can get—but will they stay if anything better turns up? It would, to say the least, certainly be a great saving in disappointments on the part of those

seeking situations, also unnecessary trouble in letter writing and interviewing to ladies and gentlemen, head gardeners, and others if they would kindly state fuller particulars in their advertisements, and above all to specify the amount of wages offered. Persons answering advertisements where wages are stated should be prepared to accept such terms; whereas, when wages are not stated, many answer them, and possibly get chosen from the numbers applying who, after the trouble and probable inconvenience of interviewing, have to say, "No, thank you," simply because the terms are too low. *A. G. L.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

NOVEMBER 9.—Present: Dr. M. T. Masters (in the chair); Mr. Michael, Rev. W. Wilks, Dr. Müller, Prof. Church, and Rev. G. Henslow (Hon. Sec.).

Cattleya labiata, Sport.—Dr. Masters observed that sports similar to those produced at the last meeting, in which two sepals were more or less resembling the labellum, had been sent to him from numerous localities this year. The species was introduced some fifty years ago, and subsequently lost; but it had been lately re-discovered and introduced from Pernambuco.

Carnation Leaves with Horn-like Marginal Outgrowths.—Mr. Michael reported that no trace of acari could be seen, as suggested as a possible cause. Dr. Müller observed that a plant of *Solanum jasminoides* was covered all over with horn-like excrescences. Dr. Masters suggested that they were probably spongy outgrowths from the epidermis.

Stocks, &c., Attacked by Beetles.—Mr. Michael observed that Stocks, Virginia Stocks, and *Nasturtiums* in his garden were attacked and utterly spoilt in a fortnight by thousands of beetles eating the flowers of the two former plants, but the leaves as well of the last-named. They do not entirely kill the plants, which renew both leaves and flowers after the beetles have disappeared. A partial remedy was found in shaking the plants over a basin of hot water. It appears to be *Phyllotreta atra*, one of the numerous "flea-beetles." Miss Ormerod, to whom they were sent, suggests "trying a mixture of equal parts of fresh gas-lime and quicklime, with a much smaller proportion of soot, and about half as much sulphur as of soot. These should be powdered up together very finely, well mixed, and dusted on to the foliage when the dew is on it, morning or evening. Just a sprinkling is enough. It usually acts well if applied as above so as to adhere to the beetles and foliage." She was under the impression, however, "that lime similarly applied would do equally well."

Ivy attacked by Dodder.—Mr. Chas. Herrin of Dropmore sent specimens of Ivy badly attacked by a *Cuscuta europæa*. He remarks, "This parasite has established itself on the west wall of our church, destroying the Ivy with which it is covered. It has been thoroughly destroyed, Ivy and all once, a few years ago; but now that the Ivy has begun to grow nicely again, half covering the wall, it has again appeared, and is destroying it." As the seeds must germinate in the ground, or perhaps in the cracks in the wall as well, the aim must be to kill them before germinating. If the ground by the wall received a good dressing of slaked lime, such might prove effective.

Cot's Orange Apple Striped.—Mr. G. Swales, of Beverley, sent an Apple, mostly red, but striped with green on one side, the latter colour being on the most exposed side. The cause was unknown. Dr. Masters suggested the possibility of accidental crossing having been the cause, for Darwin had described similar results in an Orange pollinated by a Lemon (*Ann. and Pl. under Dom.*, i., p. 399). Mr. Wilks mentioned that a *Bourré d'Amant* Pear in his garden had thrown out a green striped sport, also a bough bearing golden foliage.

Gall on Jessamine.—Mr. Henslow exhibited a large globular gall which he had taken from the stem of this plant. As no fungus was present, it was sent to Mr. McLachlan for examination.

Composition of Potatoes.—Professor Church gave some account of the recent researches of MM. Coudon and Busard on the distribution of the constituents in Potatoes. They found that a slice of a Potato revealed three zones. The external one beneath the epidermis contained 73 per cent. of water, the central holding about 80 to 84 per cent.; that the central part contained the greater amount of nitrogen, the exterior the greater quantity of starch. This accounted for the "bursting" in a floury Potato, which is relatively more free from albuminoid matters. The cause of the interior portion being more consistent is that the starch cells though bursting are held together by the curdling of the albuminoid matters during cooking. The same peculiarities appear in the thirty-four varieties examined. The intermediate zone was also of an intermediate character with regard to its structure and cell contents. It was to be regretted that the authors did not distinguish between the true albuminoids and the amides in estimating their percentage of nitrogenous matter. As a rule, the former amount to 1.3 in Potatoes, but they had estimated them from the total nitrogen as from 1.8 to 2.5. Dr. Masters remarked that these observations

corresponded with the stem-structure of the Potato, in which the cortex was a starch-reservoir as it is in trees while the deeper layers correspond with the phloem or protodermis holding sieve-tubes.

CARDIFF CHRYSANTHEMUM.

NOVEMBER 3, 4.—The eleventh annual exhibition was held in the Park Hall on these dates. Although exhibits were rather fewer than usual, the attendance was large on both days.

The finest flower in the show was shown by R. A. BOWEN, Esq. (gr., Mr. H. A. Joy), a magnificent specimen of *Phœbe*. He won also the 2nd prize in the open large class.

The twenty-fourth incurred class consisted of a remarkably excellent, even lot of blooms. The prize-winners were Sir C. PHILLIPS (gr., Mr. Dumble), and R. W. D. HARLEY, Esq. (gr., Mr. J. Robinson).

The groups were well arranged, but they were weak in foliage plants. The best was set up by Mr. W. TRESEDER, and the next best by Mr. J. GUNS. Mr. W. TRESEDER was likewise winner of the Society's Gold Medal for the highest aggregate number of points.

The best group, consisting solely of Chrysanthemums, was Mr. E. JENKINS', the good quality and freshness of the plants and flowers leaving little to be desired.

Mr. H. A. ALLEN, Pen-rth, showed the finest stand of twenty-four blooms of Japanese; and in a similar class, but unrestricted as regards varieties, Sir C. PHILLIPS had the finest blooms, and Mr. R. W. HARLEY had the 2nd best stand. The Challenge Cup, value 5 guineas, falls therefore to Mr. Dumble, Sir CHARLES' gr., who has worked hard to win it.

For twenty-four blooms of Japanese, in twelve varieties, confined to exhibitors living within a radius of twelve miles, a Cup of the value of 5 guineas went to Messrs. Cass BROTHERS, Cardiff; Mr. R. A. BOWEN coming 2nd.

The special prize for twelve Japanese, distinct, introduced in 1896 and later, shown by those who have not taken a prize for Chrysanthemums at Cardiff, was taken by Mr. H. A. ALLEN, Mr. J. GUNN coming next in order of merit.

Non-competing exhibits were those of Mr. W. TRESEDER, who had Roses and Cactus Dahlias; and of Messrs. CLEVER, of Manchester, who had miscellaneous cut blooms and fruit.

There were, in addition to the "Mums," fruits in collection, vegetables, &c., in competition, and cottagers' exhibits.

SWANSEA CHRYSANTHEMUM.

NOVEMBER 4, 5.—The sixth annual exhibition of Chrysanthemums, Fruit, &c., organised by a Committee of the Working Men's Institute, took place on the above dates, and was without doubt the finest and most successful ever held in Swansea. Since the last show, the Society has become affiliated with the National Chrysanthemum Society, and this year offered a Silver Medal for best group, and Certificates for best specimen plants.

In the open class of twenty-four Chrysanthemum blooms, incurred, 1st honours were taken by Mrs. TURBERVILLE, Hendrywillan House (gr., Mr. Hawkins); closely followed by the Earl of LISBURN, Crosswood Park, Aberystwith (gr., Mr. R. C. Williams).

In the twenty-four Japanese, Mrs. LLEWELYN, Raglan Hall (gr., Mr. Gilbert), was 1st.

The best collection of twelve Japanese was from Mrs. LLEWELYN; Mrs. TURBERVILLE was 2nd.

For a group of Chrysanthemums, the 1st prize and a Silver Medal of the National Chrysanthemum Society was won by JOHN DYER, Esq. (gr., Mr. Gill); 2nd, Mr. J. C. GOEVEIS.

The prize for the Champion bloom of the show was secured by Mrs. TURBERVILLE, with a grand bloom of Australian Gold.

NORTH OF SCOTLAND AUTUMN ROOT SHOW.

NOVEMBER 6.—The annual show was held at Inverurie, N.B. There was a splendid display of the various kinds of Turnips, and the principal features in this section was the closeness of the competition, and the uniformity of the exhibits, rather than the excellence of a few leading entries. The most successful competitors in the classes for Field Turnips were, Mr. WILLIAM YOOL, Glenlogie (green-top Swedes); Mr. WILLIAM SMITH, Corliestone (purple-top Swedes); Mr. WILLIAM LAWSON, Soot-mill (green-top yellows); and Mr. JAS. MURRAY, Fauchalds (purple-top yellows); while Sir GEORGE MACPHERSON GRANT, Bart., of Ballindalloch, was 1st for a collection of twenty-four Turnips, open to the larger cultivators.

Mr. GARDINER, Kenney, was 1st and 2nd for round white Potatoes, with tubers of excellent quality, shape, and colour of the Standard and Jeannie Deans varieties; and in the round coloured class, Mr. J. OGSTON, Bourtie, showed the two leading dishes which were much admired.

The white section was monopolised by the Snowdrop, and the leading dish belonging to Mr. G. PATTERSON, which was a feature of the show, carried off the special prize, for the second year in succession.

Mr. GARDINER was awarded 1st honours for long coloured varieties with a good sample of the Prizetaker, the other chief varieties being the Reading Ruby and Bountiful. This gentleman also won the prize for the best collection of forty-eight Potatoes, in which he showed some of the finest specimens ever shown at Inverurie.

In the "any other variety" class, Mr. GARDINER was 1st with Up-to-Date Potatoes (Mr. Findlay's), and it is worth mentioning that the first three prizes all fell to the same variety. Mr. MILNE, Cluny Castle, secured the 1st prize for breadmaker, a round white variety of good appearance, and unlike the old Victoria Potato.

A special prize was awarded by Messrs. BURTON & SONS, leading, for the best four dishes of specified varieties. Mr. OOSTON, Bourtie, took leading honours with a most meritorious entry, comprising Satisfaction, Reading Russet, Sutton's Seedling, and Windsor Castle. There was a splendid display of field-grown Potatoes.

For collections of thirty-six Potatoes, Mr. GERRARD, Upper Agilston, secured for the fifth time in succession 1st honours with a grand exhibit.

Fruit and Vegetables.—There was an interesting display of fruit, although some of the classes were not so large as they have been generally seen at Inverurie.

It would have been difficult to surpass the show of vegetables, which were exceptionally fine, some of the entries by Mr. J. OOSTON, Bourtie, being highly commended.

ISLE OF WIGHT.

NOVEMBER 9, 10.—The Ventnor Chrysanthemum Society held their second annual exhibition on the above dates. The principal prize-winners were Mr. W. H. Jobling, gr. to Lady LARPUA-CRAW, for cut blooms in the open classes; Mr. F. FORD, Steep-Hill Castle, for groups; Mr. W. W. SHEATH, or black and white Grapes; Mr. W. GER, for specimen-jams; Mr. DAY, for Apples; Mr. W. SHEATH, for Pears; Mr. H. DROVER, for Primulas; and Mr. G. WHITTY, for vegetables. Messrs. H. DROVER & SON staged fruits, flowers, and plants, for exhibition only. Messrs. J. CHEAL & SONS, Hawley, also staged a non-competitive exhibition of Apples.

BIRMINGHAM CHRYSANTHEMUM.

NOVEMBER 9, 10.—Birmingham is to be congratulated upon the very successful exhibition opened on the 9th inst. at Regley Hall. Competition is always very keen at Birmingham, and this year was certainly no exception to the rule. The exhibition still retains its reputation for trained plants, and some of the specimens that were exhibited were very fine indeed, especially varieties with incurved ovaries. Among trained Japanese, the varieties W. H. Lincoln and Vivand Morel were conspicuous.

The cut bloom classes were contested more keenly than the jams, especially in the cases of twenty-four incurved and twenty-four Japanese, the latter bringing sixteen collections (fine merit). Primulas, Cyclamens, floral and table decorations, fruit and vegetables, were shown in praiseworthy condition, in considerable quantity; and the non-competitive stands were tastefully arranged.

GROUPS AND PLANTS.

For the best group of Chrysanthemums and foliage plants arranged in a space of 16 feet in diameter, there were seven competitors. Owing to the small space it was perhaps unavoidable that the arrangements were a trifle stiff, but the majority of the exhibits were good, and the blooms fine.

The 1st prize including the society's Victorian Jubilee Gold Medal was won by Mrs. WHITFIELD, of Moseley (gr., W. Thomson); Mr. R. CADSBURY, Moseley (gr., Mr. G. Mannes), was a capital 2nd.

For a smaller group of similar character, Mr. T. CLAYTON, in Scar, and Mrs. ARMFIELD were the principal winners.

For nine large-flowering specimen plants of incurved varieties, Lady MARTINEAU, of Edgbaston (gr., Mr. O. Mongin) was 1st, with some grand specimens, probably the best that have been staged at Birmingham, the winning collection consisting of Baron Hirsch, Golden Empress, Lord Alcester, Queen of England, Prince Alfred, Lord Wolseley, John Lambert, Jardin des Plantes, and Empress of India; the 2nd honours were secured by J. A. KENRICK, Esq.

Lady MARTINEAU again secured 1st place for six trained specimens of incurved; Mr. J. CADSBURY was a good 2nd.

Lady MARTINEAU's excellent collection of six plants of Japanese exhibited the varieties Chas. Davis, W. H. Lincoln, Vivand Morel (very fine), Florence Davis, Wm. Seward, and Col. W. B. Smith.

In the class for twelve Chinese Primulas, single varieties, Mr. THOMSON was 1st, and Mr. POPE 2nd, and this and all similar classes were well contested and good.

For a display of floral arrangements, any design admissible, there were four entries, the winner taking the Birmingham Silver Cup, value £25. Messrs. PERKINS, of Birmingham, were an easy 1st, and the excellent exhibit well deserved the honour.

Mr. CROOK, of Birmingham, also staged a very fine exhibit.

CUT BLOOMS.

For honours in the class for twenty-four incurved varieties there were nine entries, and eventually the 1st prize was awarded to the Earl of HARRINGTON, Elvaston Castle, Derby (gr., Mr. Goodacre). The back row consisted of Duchess of Fife, Miss Violet Foster, John Lambert, Chas. Curtis (fine in form and colour), John Doughty, Queen of England, Globe d'Or, and Mr. John Murray; 2nd row: Mons. Westblane, Mrs. Robinson King, Robert Pettfield, Golden Empress of India, Miss Foster, and Lord Alcester; 3rd row: Miss Tomlin, Geo. Haigh, Mrs. G. Coleman, Joanne d'Arc, Princess of Wales, Madame Darier, Miss Haggas, and D. B.

Crane. Possibly the colours might have shown to better advantage had they been differently disposed. But the quality of the blooms could hardly have been better, and the winner deservedly won the 1st prize of £10 and the Victorian Gold Medal. The 2nd prize was secured by Lady HINDLIP, Warwick (gr., Chas. Crook). In this stand Robt. Pettfield, J. Agate, and Chas. Curtis were staged very finely.

For eighteen blooms of incurved, five competitors engaged, and the 1st prize was won by the Dowager Lady HINDLIP, Warwick (gr., Chas. Crook). The competition in this class was very keen; in the winning stand good blooms were staged of Major Bonaffon, Queen of England, J. Agate, Empress of India, Lord Alcester, Miss Haggas, and others. W. ROBERT, Esq., Standbridge (gr., J. Parkes), won 2nd honours; in this stand a very fine bloom of Duchess of Fife was noticed.

The best collection of twenty-four blooms of Japanese from sixteen entries, was staged by Mr. GLEASON of Stanmore, who, after a very keen fight, was awarded the 1st prize. He had a marvellous collection of blooms in point of size, colour, and fresh appearance. His back row consisted of Mme. Carnot, Duke of York, A. H. Wood, Chas. Davis (very fine), M. Pankoucke, Australis, Eva Knowles, and Simplicity; 2nd row: International, Australian Gold, Mr. Geo. Palmer, Etoile de Lyon (one of the finest blooms that was staged of this variety), Mutual Friend, M. Chamon de Leché, Phœbus, and Vivand Morel; 3rd row: Modestum (a very good yellow), Viscountess Hambledon (an extraordinary bloom of this variety), Sunstone, Mr. H. Payne, Oceana, J. Bidecove, Edith Tabor, and Mr. G. J. Hill. Mr. MEASE, Leatherhead, took 2nd place in this competition, and he had yellow Madame Carnot, A. H. Wood, Simplicity, and Mrs. W. H. Lees in extra good character. There were three other prizes in this class.

For eighteen blooms of Japanese, Mrs. SMITH RYLANDS (gr., R. Jones), was 1st, with International, Thomas Wilkins, Simplicity, Lady Hanham, General Roberts, Mrs. W. H. Lees, Mrs. Smith Rylands, Silver King, M. Pankoucke, J. Seward, J. Bidecove, M. Gustave Henry, C. H. Payne, Mrs. S. Servis, Dorothy Seward, Edith Tabor, and Mutual Friend. The 2nd place was filled by Mr. FOSTER, Havant, who staged that very fine white variety, Mrs. J. Lewis, and in this stand there were some good blooms of Mrs. H. Long and Mr. Chas. Bluck.

For six blooms of one variety white Japanese, Mrs. SMITH RYLANDS was again 1st with good blooms of Thérèse Rey.

In the class for twelve specimen blooms, arranged on long stems with Ferns, Palms, and other foliage artistically displayed, Mr. F. DAVIS was placed 1st, and Right Hon. JOSEPH CHAMBERLAIN 2nd. Mr. DAVIS also took 1st prize for a collection of six blooms of a yellow-flowered Japanese.

The best collection of twelve Anemone flowers were from Mrs. SMITH RYLANDS with some good blooms of Sir Walter Raleigh, John Benjamin Webster, Lady Benedict, and Descartes.

FRUIT.

In the class for a collection of British-grown fruit, Mr. GOODACRE was a good 1st, and took the Gardeners of Birmingham Victorian Diamond Jubilee Silver Cup, value £15. In Mr. Goodacre's collection was a background of Grapes, black and white, fine in berry and colour; and in front Pines, Melons, Apples, Pears, &c., the whole occupying a space of 50 square feet. The exhibit was of an all-round good quality, and well fitted to illustrate the beauty of well-grown British produce; Messrs. GEO. BUNYARD & CO, Maidstone, were 2nd with a nice even collection, but evidently many points behind Mr. Goodacre.

Grapes were shown in quantity, and the principal prize-winners were Mr. H. F. HAYWARD, Mr. GOODACRE, Lord Powis, Earl of DENBIGH, and Lord BACOT.

The local classes for Grapes, and Apples and Pears, brought forward some specimens of fruit, good in size, shape, and colour.

VEGETABLES.

The vegetables exhibited were marvellous in quantity and quality, and better than have been shown at Birmingham previously. Liberal prizes were offered by Messrs. THOMSON & SONS, Messrs. POPP & SONS, Messrs. SUTTON & SONS, Messrs. WEBB & SONS, Messrs. SIMPSON & SON, and Mr. ROBERT SYDENHAM. The principal prize-winners were Lord CANARVON, Lady THEODORA GUEST, the Dowager Lady HINDLIP, Right Hon. JOSEPH CHAMBERLAIN, and several others, more or less local.

NON-COMPETITIVE EXHIBITS.

A great many firms sent exhibits not for competition, amongst whom may be mentioned, Messrs. CUTBUSH & CO. Highgate, who had Begonia Gloire de Lorraine, Adiantum Farleyense, and Palms; Mr. STEVENS, Birmingham Arcade, staged a collection of floral designs and dried foreign grasses, very bright, but rather artificial in appearance; Messrs. WEBB & SONS, Stourbridge, had well grown Onions, &c.; M. J. MORT, Esq., staged a collection of fruits; and Mr. W. B. ROW, Barbary Nurseries, Worcester, had a stand of cut flowers and fruit: The Right Hon. JOSEPH CHAMBERLAIN staged a collection of Chrysanthemums shown with their natural foliage, a very striking exhibit; a collection of Cacti from Mr. J. A. WALTON, of Handsworth, which attracted a deal of attention; Messrs. THOMSON staged a beautiful lot of Primulas; Mr. WELLS, of Earlwood Nurseries, sent a box of thirty six Japanese Chrysanthemums, which were much admired; and Messrs. H. CANNELL & SONS, of Swanley, staged a collection of vegetables to illustrate the field culture.

One of the best honorary exhibits was a collection of vegetables that was staged by Mr. EMPSON, 1st to Mrs.

WINGFIELD, of Amphilhill, Boda. The Carrots, Leeks, Cauliflowers, &c., were greatly admired, and some very complimentary remarks were made to Mr. EMPSON respecting this exhibit.

The duties of judging were undertaken by Mr. OWEN THOMAS, Mr. A. F. BARRON, Mr. W. KIPPE, Mr. PARKES, Mr. DOWNES, and Mr. A. COOMES; and much praise cannot be given to Mr. HUGHES, secretary, and a colleague for the energy and diligence that resulted in so fine a show.

LEEDS PAXTON.

NOVEMBER 9, 10.—The ninth annual Chrysanthemum exhibition of this Society was held in the Town Hall. The exhibition may be placed in the front rank amongst the Chrysanthemum shows of the North of England. The entries were more numerous than on any previous occasion, being between 500 and 600. The quality of the exhibits was better than formerly, especially that of the Chrysanthemum groups, and the cut blooms in the local classes.

The specimen and foliage plants were tastefully arranged on the orchestra, and the Chrysanthemum groups on one side of the hall. Miscellaneous groups occupied the other side, and the cut flowers, table plants, and fruit were staged on tables running across the hall. The bouquets, sprays, and button-holes were arranged on tables in front of the orchestra, on each side of an artistic design of fruit, flowers, and autumn-tinted leaves, arranged by Mr. GRIZ, gr. to Sir J. KIRSON, Bart., and Mr. A. WALKER of Messrs. SHAW BROS., florists, Leeds, and frozen in a large block of ice by Mr. THOMSON, of the Leeds Ice Storage Co.

In the groups of Chrysanthemums, the addition of six foliage plants and Ferns relieved the effect considerably. The 1st prize was justly awarded to Mrs. BOWRING, Allerton Hall, Gledhow, Leeds (gr., Mr. W. Moore); J. RHODES, Esq., Potternewton House, Leeds (gr., Mr. R. Mason), was 2nd with a well-arranged group, but the plants were of less good quality.

The miscellaneous groups in the local class showed good culture, but the arrangement might have been freer. The 1st prize group was much the best, and was exhibited by M. KITCHEN, Esq., Elles Close, Roundhay (gr., Mr. Ganble).

In the open class for miscellaneous groups there was only one exhibitor, E. B. FABER, Esq., J.P., Belvedere, Harrogate (gr., Mr. Townsend), who set up a magnificent group.

CUT BLOOMS.

In the open class for twenty-four Japanese blooms, Mr. R. A. BOWRING, The Heath, Cardiff, took 1st honours with most magnificent blooms. The following varieties were remarkable: Simplicity, a superb bloom, which gained the special prize for the best Japanese in the exhibition; Etoile de Lyon, Chas. Davis, Vivand Morel, John Seward, Duke of York, Phœbus, Australian Gold, W. Seward, Miss Teichmann, and Mrs. W. Weeks. A. WILSON, Esq., Tranby Croft (gr., Mr. Leadbetter), was 2nd with a good stand.

In the open class for eighteen incurveds, the Rt. Hon. the Earl of HARRINGTON (gr., Mr. Goodacre), exhibited a splendid collection, with which he won the society's Challenge Cup. Having won the Cup in this class for the second time in succession, the Cup now becomes Mr. Goodacre's own property. A. WILSON, Esq., again showed well for 2nd place.

In the open class for twelve blooms, distinct, A. WILSON, Esq., was 1st; Mrs. WHITAKER, Cliff House, Hemble, near Hull, 2nd.

In the local classes for cut blooms there was noticeable marked improvement, and some of them would have scored well in the open classes, especially the twelve incurved, and the twelve Japanese, distinct, exhibited by Mrs. BOWRING's gr., Mr. Moore, with which he won the two Challenge Cups. The Cup offered in the incurved class becomes Mr. Moore's property. Sir J. KIRSON was a good 2nd in both classes.

There was a fine display of bouquets, sprays, and button-holes. Vegetables were extensively shown, but the exhibits of fruit were not so numerous, nor were they of such good quality as formerly.

The judges were Mr. JELLOCO, Liverpool; Mr. WILSON, Swanland Manor, Hull; Mr. FOLKARD, Sand Hutton Hall, York; and Mr. DANIELS, Dewsbury.

KINGSTON-ON-THAMES CHRYSANTHEMUM.

NOVEMBER 9, 10.—Held as usual in the large Drill Hall, the show was of fair quality, but still seems shorn of some of its older features, groups being reduced to one class, and the large trained plants having disappeared. The group now is of a composite nature, Chrysanthemum plants, foliage and other flowering plants being combined. The effects obtained are varied, and in no case were they as good as they might have been.

Mr. PONTBURY, Ripon House Gardens, Putney, was 1st, his Chrysanthemums being aided by Eucharis, Bouvardias, Palms, &c. Mr. D. GIBSON, gr. to J. B. JOHNSTONE, Esq., Kingston Hill, was 2nd, having two-thirds Chrysanthemums, but rather stiffly group d.

For four natural bush Japanese Chrysanthemum plants, Mr. MILHAM, gr. to A. F. MILLER, Esq., Leatherhead, was 1st, his specimens, some 3 feet in height, being finely bloomed. They comprised Vivand Morel, Mons. henon de Leché, Col. W. B. Smith, and Charles Davis. Mr. PRING-

THORPE was 2nd with a single specimen. The latter was a good 1st, having a fine Boule d'Or.

Berried plants were capital, with six neat 2-feet, very handsome, pyramidal scarlet-fruited Capsicums. Mr. J. Lox, gr. to T. W. DISNEY, Esq., Kingston, was 1st; Mr. Watkins, gr. to R. W. MONRO, Esq., Coombe Warren, was 2nd.

Mr. S. Pead, gr. to R. S. BOND, Esq., Surbiton, had the best six Bouvardias; and Mr. F. King, gr. to A. F. PERKINS, Esq., Holmwood, Dorking, the best nine table plants; Mr. MILEHAM having the best six plants, and also the best six double Primulas, capitally bloomed. These are always well done in the Leatherhead district.

Cut Flowers.—The Challenge Vase class for twenty four Japanese and twenty four incurved flowers brought five competitors, the winner this time being Mr. F. KING, who takes the Vase to Holmwood for the year. He had of Japanese, *Australe* (the champion bloom of the show), *M. Chenon de Lechê*, Mrs. J. Lewis, *Modestum*, Mdle. Thérèse Rey, *Phœbus*, Edwin Molyneux, Viscountess Hambledon, Edith Tabor, Vivian Morel, Mrs. A. J. Hubbuck, *Australian Gold*, *Simplicity*, Madame Carnot, *Pride of Exmouth*, *Mutual Friend*, *M. Maurice Ricoud*, and others; and of incurved *Duchess of Fife*, Charles Curtis (the premier bloom), W. Tunnington, Lord Alcester, Bonnie Dundee, Robert Pettfield, Major Bonnafon, C. B. Whitnall, Lord Rosebery, Brookleigh Gem, with others. Mr. G. Hunt, gr. to PANTIA RALLI, Esq., Ashstead Park, was 2nd this year, having been last year's winner. His Japanese were very good, but his incurveds were rather weak. Mr. Jinks, gr. to EDOAR BRUCE, Esq., Walton-on-Thames, was 3rd, having the second best champion Japanese bloom in his stand, a fine golden *Madame Carnot*.

With thirty-six Japanese, Mr. W. Higgs, gr. to J. B. HANKEY, Esq., Leatherhead, was 1st, the blooms being of rather moderate quality. The best were *Madame Carnot*, Mdle. Gustave Henry, Vivian Morel, A. H. Wood, Mrs. H. Weeks, *Australe*, *Hairy Wonder*, *M. Pankoucke*, *M. de la Rocheterre*, &c. Mr. HUNT was a very close 2nd. Throughout this class many blooms had suffered from damp.

Mr. D. GIBSON had the best twelve Japanese in one class, Mr. SPRINGTHORPE being 2nd.

In a further class for twelve blooms, Mr. GIBSON was again 1st, and Mr. SPRINGTHORPE 2nd; Mr. H. SQUELCH, of Dorking, coming 3rd.

In the class for six white Japanese blooms, Mr. G. W. FORBES, gr. to Madame NICHOLS, Surbiton, had grand ones of *Madame Carnot*, coming an easy 1st; Mr. PEAD being 2nd with the same variety. In a further class for six, any colour, Mr. FORBES was again 1st, with good Vivian Morel; Mr. GIBSON being 2nd, with the yellow *Phœbus*; and in a third class for six blooms Mr. HIGGS was 1st with rather weak *Madame Carnot*; Mr. SPRINGTHORPE having really better blooms of *Phœbus* for the same place.

Incurved flowers now play a small part in these shows. In the class for twenty four blooms, Mr. F. KING was 1st, with fair specimens, *Globe d'Or*, Lord Rosebery, C. B. Whitnall, Robert Pettfield, Brookleigh Gem, Mrs. R. King, Chas. Curtis, and *Ma Perfection* being of the best; Mr. G. HUNT was 2nd, and Mr. HIGGS 3rd.

Mr. J. French, gr. to Mrs. BARCLAY, Wimbledon, had the best twelve blooms, Mr. SPRINGTHORPE being 2nd.

With six of one variety, Mr. G. HUNT was well 1st, with very fine *Duchess of Fife*, good C. H. Curtis coming 2nd from Mr. F. KING.

Reflexed blooms were small, Mr. C. J. Cooke, gr. to J. S. SASSOON, Esq., Walton, being 1st, and Mr. PEAD 2nd. Mr. JINKS had the best twelve *Anemones*, really good blooms. Mr. F. CARYER, gr. to A. G. MEISSNER, Esq., Weybridge, had the best twelve trebles of *Pompons*, and Mr. A. NAGLE, Kingston, the best *Anemone Pompon*. With six blooms each of Mrs. G. Rundle, Mr. Glenny, and Mrs. Dixon, Mr. FORBES was well 1st, as he was also for twelve singles in trebles, a beautiful lot of flowers.

A class for twelve Japanese blooms on long stems, set up in baskets, brought a capital competition. The 1st prize was given to Mr. G. ELLIOTT, gr. to Captain MACDONALD, West Molesey, for a broad, flat basket, the blooms well disposed, being mixed with foliage plants and grasses; Mr. BRETT, gr. to WM. CAMPBELL, Esq., Coombe Bridge, coming 2nd.

Fruit.—The collections of four dishes were very poor, the 1st prize lot from Mr. W. Taylor, gr. to C. BAYER, Esq., Forest Hill. With Black Grapes in three bunches, Mr. TAYLOR was 1st, having good Gros Colman; Mr. G. SMITH coming 2nd with the same variety; and Mr. TURNER was 3rd with *Alnwick Seedling*.

Mr. J. BURY, Byfleet, had some capital Alicantes that, on the second day in better light showed a long way better than the 3rd prize bunches. Some adverse criticisms were passed on the judging of the Grapes.

Mr. ATKINS had the best six dishes of Apples in Ribston, Blenheim, and King Pippins, *Mère de Ménéage*, Lady Henriker, and Wellington; Mr. TURNER coming 2nd. Mr. HICKS had the best four varieties of Pears, moderate samples.

Mr. C. J. Waite, gr. to Mr. PATRICK TALBOT, Esher, sent a large basket of twelve diverse vegetables not for competition.

There were numerous bouquets, table stands, sprays, buttonholes, and similar decorations set up by Lady-amateurs, but these have only local interest.

GREAT BERKHAMSTED SHOW.

NOVEMBER 9, 10.—The Chrysanthemum Society of this place held its tenth annual show on the above dates.

There were twelve more entries than last year, viz., 145, and in all classes advancement was obvious, except in that of Grapes. Chrysanthemums were well shown by Mrs.

SMITH DORRIEN, Earl BROWNSLOW, Lady CHESHAM, Mr. T. GOOCH, Mr. E. F. FIDDERDALE, Mr. W. GILLMAN, Mr. STRACHAN, and others in the bigger classes; Mrs. LIONEL LUCAS, Mr. J. LA FONTAINE, Mr. GRISTWOOD, and Mr. CLARE in the minor ones. As a speaker remarked at the dinner, the show once was filled with quantity, now it was filled with quality, and there was scarcely a weak class.

DEVON AND EXETER GARDENERS'.

NOVEMBER 10.—The subject treated of on the occasion was "Pruning and the Management of Fruit Trees," a paper by Mr. T. H. SLADE, gr. to Lord POLTMOORE, at Poltmoore Park.

It was important in planting Apple trees, said the lecturer, to bear in mind the kind of stock Apples were grafted on, as if on *Paradise*, 8 to 12 feet apart would be sufficiently wide, but 12 to 20 feet was necessary for Apples on the Crab stock. Where space was limited, the *Paradise* stock should be preferred.

When the soil was very good, he recommended planting near the surface; and in pruning the roots, he advised pruning them so as to induce the new roots to strike upwards, and thus get the benefit of the sun's action on the soil.

Fears that the roots of Apple trees might be injured by frost were groundless. Where a tree continued to make about 9 inches of good solid growth annually, it was not in need of root pruning; but when this treatment was necessary owing to excessive growth of wood, there should be a fair balance aimed at between the ramifications of the roots, and the spread of the top branches.

Orchard Apple trees which were planted 30 feet apart, required little, if any, root pruning, as they would in time reach a bearing condition, and that alone would check any tendency to make wood at the expense of bloom.

Where orchard trees were planted in the autumn, pruning should be practiced in the spring. An orchard standard tree should have a stout, clean stem, and about six main shoots. It was easy to multiply the shoots by shortening existing ones to 3 or 4 inches, and it was a mistake to give the tree too much work to do, by allowing shoots to remain at their full length during the early years of the life of a tree.

With regard to Pear trees, the crowns should be kept thin, and only some of the branches pruned back. In pruning Pear trees some recommended pruning the top first, and then, at an interval of a week or a fortnight, the lower part of the tree, but he did not think this was necessary.

In pruning espaliers, the leaders or principal shoots should be left unshortened in order to induce the formation of fruit-buds in a natural manner. The greatest care should be taken, in choosing trees, on the right kind of stock. He had seen Pears grafted on Thorns, but, of course, such trees were worthless. As to summer pinching, the grower must be guided by the season, but, in any case, it was well to leave it as late as possible in the summer.

If Cherries made too much wood, a salutary check would be administered by mixing rubble with the soil. As to the blistering of the leaves of Peaches, he thought it was caused by cold winds in spring, and not, as some supposed, through dryness at the roots. Mildew and other pests should be sharply looked after, and taken in hand in time. He strongly advocated the autumn grease-band remedy for fruit-trees, prevention being infinitely preferable to cure in this case. Mr. SLADE illustrated his lecture by placing several fruit-trees before his audience, and pointing out the results of bad grafting, and the effects of different kinds of treatment. With the usual vote of thanks, after a rather spirited discussion, the meeting terminated.

MONMOUTH CHRYSANTHEMUM.

NOVEMBER 10, 11.—After a lapse of six years, this Society held a show with very satisfactory results in the Rolls Hall, Monmouth, on the above dates.

Cut Blooms.—There were seven exhibitors in the class for twenty-four Japanese, and the 1st prize was taken by Mr. LOCKYER, gr. to J. C. HASBURY, Esq., Pontypool Park, with wonderful blooms of *Amiral Avellan*, Duke of York, Mrs. C. Bick, *Madame de Molin*, *M. Chenon de Lechê*, *Edwin Molyneux*, &c.; Mr. DAVIS, gr. to A. W. S. WRIGHT, Esq., Quarry House, Linton, who was a close 2nd, had *Australian Gold*, *Oceana*, Edith Tabor, *sunflower*, *Madame Carnot*, *Simplicity*, &c., in grand form.

In the class for twelve Japanese, Mr. BYFORD, gr. to C. LEE CAMPBELL, Esq., Glewston Court, Ross, was an easy 1st, with superb blooms of *M. Chenon de Lechê*, *Phœbus*, *International*, *Pride of Malford*, *Elsie Teichmann*, Mdle. de M. Gilbert, *M. Gruyer*, &c.; 2nd, Captain HOGWOOD, Mount Craig.

Here again Mr. LOCKYER had the post of honour for twenty-four incurveds, the blooms large and well finished, of *Miss Haggas*, C. Curtis, *Empress of India*, *Duchess of Fife*, *Madame Darier*, &c.; 2nd, Mr. PITT, Abergeenny, who also had a good stand, including a magnificent bloom of C. Curtis.

A. KNOWLES, Esq., Newent Court, Gloucester, who was placed 1st for twelve incurveds, had well-finished flowers of *Major Bonnafon*, *J. Agate*, &c.; Mr. BYFORD being a good 2nd.

Groups of Chrysanthemums.—In point of merit, the groups were not the equal of the stands of cut blooms, although the best of them, one arranged by Mr. Phillips, gr. to J. M. BANNERMAN, Esq., Wyatstone Leys, was particularly good; C. M. CROMPTON ROBERTS, Esq., Drybridge, Monmouth, followed closely with plants having better flowers, but less satisfactorily arranged.

Wreaths, bouquets, Apples, Pears, and vegetable exhibited in excellent examples; while not the least fine features were some non-competitive exhibits, a large collection of Apples from Mr. BASHAM, Pa Nursery, Newport, similar to that he staged at Hereford week; and a large group of plants from Lord LLEWELLYN, which consisted of *Eucharis grandifolia*, *Cypripediums*, *Chrysanthemums*, *Palms*, *Ferns*, &c.

NORTHAMPTON CHRYSANTHEMUM.

NOVEMBER 10, 11.—This successful Society held its sixth annual exhibition in the Corn Exchange, and play was a better one than the Society had previously. The groups contained better blooms than in former years. Primulas are always good at this show, and effort made this season to win the prize from the champion grower of the last two years, but without success. Bateman, gr. to R. LEE BEVAN, Esq., Brixworth Hall, again 1st, although some of his competitors staged the variety.

Cut blooms of Chrysanthemums were very good in the show. We remarked two blooms of Mrs. J. Lewis and *Sin* that were better than we have previously seen these ties. A strong spirit of rivalry exists between the amateurs of the Northampton district, and some of the blooms by them this year would have been creditable to the classes.

GROUPS AND PLANTS.

For the best group of Chrysanthemum plants the three competitors, and the winner was found in Mr. GRAY, gr. to Mrs. COULSON, Cliftonville, Northampton, arrangement of well cultivated plants was very stylish. Mr. SODEN, gr. to Mr. F. G. ADAMS, Northampton, was 2nd with a fairly good group.

For six Japanese, distinct varieties, Mr. REEVE was placed 1st, amongst them being a very well grown *Phœbus*, Vivian Morel, and also Wm. Tricker; Mr. SODEN was 2nd.

In the amateurs' classes for groups, Mr. BARRAWAY, Thrift Street, was 1st, with a splendid group.

CUT BLOOMS.

For eighteen incurved varieties, Lord SPENCER, Park, was a good 1st out of five entries, having some fine blooms of C. B. Curtis, John Lambert, Ma Perfection, W. Tunnington, and Major Monmouth. Mr. COPEMAN with good *Baron Hirsch* and Duke of Fife, the last bloom was not quite developed.

Mr. REEVE took the premier honour for twelve incurveds having very fine blooms of *J. Agate* and *Empress of India*.

In the class for eighteen Japanese (distinct, from entries. Mr. PEARCE was placed 1st, who had good blooms of Mrs. J. Lewis, Vivian Morel, and *Simplicity*.

For twelve Japanese, introduced since 1833, Mr. I was again 1st with fine specimens of Mrs. J. Lewis, Gruyer, *Phœbus*, *Madame Carnot*, *International*, *Sin*, Chas. Davis, and G. Hubbuck, *Pride of Exmouth* (a bloom), Lady Ridgway, and *Australian Gold*. Mr. COPEMAN was a very fine Mrs. J. Lewis in the stand.

For six Japanese introduced in the spring of 1894 and 1895, Mr. COPEMAN was 1st with six beautiful blooms of *J. Lewis*, *Australian Gold*, *Miss Goschen*, *Lady Byron*, *A. de Rothschild*, and C. W. Richardson.

The rest of the cut bloom classes were well contested.

MISCELLANEOUS.

Mr. WOODS was 1st in table decoration; and for table Mr. HAYES secured the principal honour. Mr. HAYES also 1st for bouquet and wreath.

Fruit and vegetables were well shown, Mr. COLE, gr. to SPENCER, being 1st for vegetables; and Mr. BATES for Grapes.

Two very pretty stands of miscellaneous fruits and were shown by Messrs. JOHN PERKINS & SONS; also TIOS PERKINS & SONS, both of Northampton.

The judging was undertaken by Mr. W. DROVER, of Ham, Hants; Mr. G. Glover, Esher; Mr. F. P. Northampton; and Mr. Collins, Berry Wood.

CHELTEMHAM, &c., WINTER FLOWERS EXHIBITION.

NOVEMBER 10, 11.—At this annual exhibition which has been continued for a period of twenty-seven years, the farmer and the gardener join hands; the former stage of various kinds of ponderous proportions, and even Cow-cabbages, with grain of various kinds; and the latter supplies Chrysanthemums, fruit, and vegetables. The of the assembly rooms is given up to the gardeners, he has to put his vegetables in another for lack of space, while other rooms have farm produce in great quantities. It is an exhibition somewhat unique of its kind, and the Mayor of the town occupies the chair at a luncheon the awards are made.

Chrysanthemums.—There were several classes for most of them trained specimens, but with few exceptions they were wanting in foliage. Messrs. SMITH & SON, George's Road, had the six best incurved specimens.

JAMES PILGRIM, Pitville Nursery, the best six Japanese. In the class for a group of plants, a remarkably fine was made by Mr. G. W. Marsh, gr. to T. B. BUTT, Esq., Court. Every plant was characterised by fine growth.

carried splendid blooms. Mr. W. Lusty, gr. to Colonel Rogers, Battledown Court, was a good 2nd, having fine blooms.

Some excellent cut blooms were staged, and there was a close competition in most of the classes. The best eighteen varieties of incurved Chrysanthemums came from Mr. G. W. Marsh; Mr. W. Lusty was a very close 2nd indeed. The blooms in the latter had size and evenness, and those in the former rather more refinement.

Mr. Lusty was an easy 1st with eighteen blooms of fine character; Mr. W. Hillier, gr. to Lady Northwick, was 2nd.

With twelve incurved, Mr. W. Child, gr. to the Earl of Coventry, Severn Stoke, was 1st, having in excellent character Mrs. J. Kearns, C. H. Curtis, and Jeanne d'Arc; Mr. J. Mullins, gr. to Col. Arbuthnot, Gloucester, was 2nd.

Japanese Chrysanthemums were finely shown; the best thirty-six blooms, which were well ahead of anything else, came from Mr. J. Martin, gr. to T. W. Swinburne, Esq., Corndean Hall, who had very fine blooms of Madame Carnot, Phœbus, Edith Tabor, A. G. Hubbuck, Hairy Wonder, Beauty of Teignmouth, Mrs. R. Jones, Ethel Addison, and Robert Owen; Mr. G. W. Marsh was a good 2nd.

Mr. W. Hillier was 1st with eighteen blooms, showing some very good ones; Mr. Marsh was 2nd.

With twelve blooms, Mr. J. L. Burgess was 1st; and with six blooms, Mr. J. Maddocks, gr. to J. Harlick, Esq., Cowley Manor.

Button-holes, sprays, bouquets, and vases of Chrysanthemum blooms were shown in several classes.

Table plants, Cyclamens, Mignonette, and Chinese Primroses were also shown.

Fruit and Vegetables.—Culinary and dessert Apples were in fine character, and brilliantly coloured. The best collection of twelve dishes of culinary, which included well-known sorts, came from Mr. A. James, gr. to Viscount Deerehurst. Mr. J. Mullins had the best four dishes.

The best twelve dishes of dessert Apples came from Mr. A. James, a very good selection; Mr. Child was again 2nd.

The 1st prize for four dishes of dessert Apples, distinct, was won by Mr. G. Cliff. Single dishes of culinary and dessert Apples were also shown. Mr. A. James also took the 1st prize with 12 dishes of Pears, showing good fruits.

Mr. A. James had the best two bunches of Black Grapes, showing well finished Alicante; and he was also first with White Grapes, having well-coloured Muscat of Alexandria.

Vegetables were in good character generally. Mr. Alfred Cook had the best eight dishes; Mr. Child took Messrs. Sutton & Sons' 1st prize for six varieties; Mr. Alfred Cook was 1st with six dishes, the prize offered by Messrs. G. F. W. Yates. The arrangements were excellent in the hands of Mr. S. Sharpe, the Hon. Secretary.

DONCASTER CHRYSANTHEMUM.

NOVEMBER 10, 11.—The principal features at this charming show were the superb groups, and the general arrangements reflected great credit on the powers that be.

Mr. Alderman gained the special prize for the premier bloom in the show, and the same gentleman was 1st for twelve Japanese, twelve incurved (nine distinct), and twelve incurved (eight distinct). Mr. Keywood, gr. to W. H. B. Wrightson, Esq., Cusworth Hall, showed superb blooms of Madame Darier, Jeanne d'Arc, and Golden Empress, in his 3rd prize board in the class for nine distinct blooms.

There were but three competitors in the class for a group arranged for effect, Mr. H. Butcher, gr. to W. Chadwick, Esq., Arksey Hall, being 1st with some fine blooms that might, however, have been more happily blended in regard to their colours; Mr. Keywood came 2nd.

For miscellaneous groups Mr. Hill, who has but lately taken over the charge of Mr. Morris' gardens at Beechfield, was well 1st.

In the district class, Mr. Butcher was 1st for six incurved blooms dissimilar, closely followed, however, by Mr. West, gr. to Sir Wm. Cooke, Wheatley Park. In the six dissimilar reflex class, Mr. Butcher, Mr. West, and Mr. Keywood, were placed in the order named.

For twelve Japanese (nine dissimilar), Mr. Keywood, C. W. Blagden, Esq., and Mr. West, were respectively placed in the position of their names.

Fruit, &c.—The best white Grapes were shown by Mr. Butcher, whilst Mr. Alderman secured the 1st prize for black Alicante.

Mr. Keywood secured 1st place for cooking Apples, with Warner's King; whilst Mr. Brown, gr. to R. S. Schofield, Esq., was 1st in the dessert class.

Pot plants made a poor show, but everything else was excellent, and reflected great credit on the secretary and committee.

UXBRIDGE AND DISTRICT CHRYSANTHEMUM.

NOVEMBER 10, 11.—This Society held its second annual show of Chrysanthemums, fruit, and vegetables in the Town Hall.

Mr. W. Batchelor, gr. to C. B. Leake, Esq., Harefield Park, was 1st for a group of Chrysanthemums, in which were some fine blooms of Mrs. Weeks, Edith Tabor, Mutual Friend, and Phœbus.

In a class for "single-handed gardeners," Mr. Taylor, gr. to G. Wills, Esq., Dileford Manor, was 1st for a group of Chrysanthemums; and Mr. G. Bull, gr. to A. M. Tarleton, Esq., Breckspers, was 1st for a group of miscellaneous plants. Mr. Daley, gr. to C. M. Wakefield, Esq., had the best specimen plants.

In the open class for twenty-four Japanese blooms, Mr. S. Melbeck was 1st; and for twenty-four incurved blooms, Mr. Watson, gr. to F. Cox, Esq., was the winner.

Most of the remaining classes were reserved to members. There was good competition in the classes for fruit and vegetables.

MAINDEE AND DISTRICT CHRYSANTHEMUM.

NOVEMBER 11.—The eleventh annual show took place in the Gynnasium, Newport, Mon., a spacious hall well adapted for a flower show. The attendance was most encouraging, and the exhibits on the whole were good, the groups being especially fine.

The best group of Chrysanthemums (open) was staged by Mr. G. Stedman, Maindee Nursery, who had a well arranged group with blooms of the finest quality; the best were Edith Tabor, Chas. Davis, Etoile de Lyon, M. Chenon de Leché, and Phœbus.

S. Dean, Esq. (gr. to Mr. B. Giddings), had the best four dwarf-trained Chrysanthemum plants, and the best three pyramidal-trained Chrysanthemum plants.

Col. J. Hanbury, Pontypool Park (gr. to Mr. J. Lockyer), won the 1st prize for twelve Japanese blooms distinct. The following were well staged: Duke of York, Mutual Friend, Mrs. C. Blick, Vanden Heede, and G. C. Schwabe. Col. J. C. Hanbury had also the best collection of six cut blooms incurved.

The best group of Chrysanthemums in the Gardeners' Class was from S. Dean, Esq. (gr. to Mr. B. Giddings). The plants were well foliaged, the blooms were fresh and of good size, the colours being well blended.

The best group of miscellaneous plants was from C. H. Bailey, Esq. (gr. to Mr. Sharpe). This was the finest exhibit in the show, and most tastefully arranged.

Trade Exhibits included one from Mr. William Treseeder, Cardiff, comprising Cactus and single Dahlias, Roses, Chrysanthemums and bouquets.

Mr. John Basham of Fair Oak Nurseries, Bassaleg, Mon., staged an immense collection of Apples.

WINCHESTER.

NOVEMBER 11, 12.—An excellent exhibition in every respect was that held in the Guildhall, Winchester, on the above dates; and Mr. C. Shenton, the hon. secretary of the society, may be heartily congratulated upon the success that has attended his efforts.

In the cut bloom classes Mr. W. G. Adams, 89, Clarendon Road, Southsea, won the premier award for forty eight, half of which were Japanese and half incurved varieties; and especially meritorious were the blooms of the latter. Mr. W. Neville, gr. to F. W. Flight, Esq., Twyfoe d, Winchester, was 2nd, his strength lying in the Japanese section.

Mr. J. Bowerman, gr. to C. Hoare, Esq., Hackwood Park, Basingstoke, took the 1st prize for twenty-four Japanese varieties, the blooms shown being highly coloured, and of a size almost too large to allow of their being properly seen upon the show-board. Mr. P. West, gr. to H. J. Wigram, Esq., Northlands, 8 Salisbury, was 2nd.

In the classes for twelve and for six incurved varieties, Mr. Adams was 1st in each; Mr. Neville being awarded the 2nd place in each. The latter exhibitor was the winner in the twelve flower class for white Japanese in four varieties, with capital blooms of nicely chosen varieties; and Mr. Bowerman secured a similar award for the same number of yellow or bronzy-flowered varieties.

Mr. Best, gr. to F. D. Leyland, Esq., The Vine, Basingstoke, was 1st for twelve blooms of any other colour; but he was very closely followed by Mr. Bowerman.

Groups of Chrysanthemums were shown in the best manner by Mr. Street, gr. to the Rev. Dr. Fearon, Winchester College, with plants and blooms of the finest quality; Mr. G. Newman, gr. to Captain Gausson, Twyford Lodge, Winchester, coming in really good 2nd.

Plants to show for conservatory decoration and specimens were capital, especially those sent by Mr. G. Adams, gr. to Col. F. A. Dickens, Blackbridge; and by Mr. Holloway, gr. to Mr. A. Brown Hill, The Farm Dairy, Southampton, who were awarded 1st, 2nd, and 3rd prizes in the order of their names.

Mr. A. Taylor, 3, Hillside Terrace, Winchester, had the best specimen trained plant in Golden Christine.

Mr. E. Can, gr. to N. A. Gillett, Esq., Fair Oak Lodge, Bishopstoke, won the leading award for a group of miscellaneous plants arranged for effect, and in which some Orchids in flower formed a prominent feature. Primulas, Cyclamens, and table plants, fruits, and vegetables were creditably shown.

Mr. E. Molyneux, gr. to W. H. Myers, Esq., M.P., Swanmore Park, Bishop's Waltham, sent a pleasing exhibit of cut Chrysanthemums, consisting of Japanese, incurved, Pompon, and single flowered varieties.

BECCLES CHRYSANTHEMUM AND FLORICULTURAL.

NOVEMBER 11, 12.—The eighth annual show of the above society was held in the Town Hall, Beccles. In the open classes for plants in pots the entries were not so numerous as in previous years, but the falling off in this respect was more than compensated by the excellence of the exhibits.

For three Chrysanthemums in pots, E. Masters, Esq., Beccles, again took premier honours in the classes for Japanese, incurved, reflexed, and Pompon varieties, also

for three standard trained plants. This is the eighth consecutive year Mr. Masters has held this position.

There was a fine display of cut blooms, and the competition was very keen. For twenty-four Japanese Sir R. Beauchamp was awarded the 1st prize for a very even lot; N. Bacon, Esq., Raveningham Hall, was a close 2nd.

The best collection of twelve Japanese was from F. Penn, Esq., Benacre Hall.

There was a fair show of incurved varieties. The best twelve were staged by Mr. A. Bishop, Westley Hall, Bury St. Edmund's; and best six by Mr. J. C. Sharpe, Beccles.

The classes for amateurs were well filled, Mr. W. Albores, Beccles, taking the principal honours both for plants in pots and for cut blooms.

Fruit and vegetables were of good quality. N. Bacon Esq., exhibited the best collection of fruit, and Sir R. Beauchamp the best basket of vegetables—six dishes; also the best basket of salad. There was also the usual display of epergnes and hand-bouquets.

PUTNEY, WANDSWORTH, &c., CHRYSANTHEMUM.

NOVEMBER 11, 12.—There has been much new life infused into this Society during the past season or two. A good deal of work has been done which is likely to result in making the exhibition of some importance outside the immediate locality, hitherto its only sphere of influence. The show held in the Cromwell Hall was the twentieth held at Putney, and as will be seen below, some of the exhibits were very fine.

Since the last year's exhibition was held, there has been subscribed a sum of money for the provision of a Challenge Cup, value £25, and this was awarded in the Tradesmen's Commemorative Class for sixty cut blooms. The Cup (which is exceedingly handsome) will become the property of the exhibitor that shall first win it in competition on two occasions, not necessarily consecutive ones; and conditions have been made in favour of exhibitors to prevent the Cup remaining the property of the Society for a lengthened period. This class was decidedly the most interesting one at the show just held, and the rest were generally satisfactory. The arrangements were in the hands of Mr. J. F. McLeod, Hon. Secretary, and were capital.

The groups of Chrysanthemum plants were only permitted 40 feet superficial space each, but not fewer than twenty varieties were to be represented by the plants. Such a small space admits of but one method of arrangement; and an exhibit from Mr. W. Bedwell, gr. to — Lambert, Esq., North Avenue, was good, his blooms being very commendable. The class for groups of miscellaneous plants arranged for effect brought five exhibits, several of which were very pretty. The best came from Mr. A. Methven, gr. to W. Keith, Esq., Fernwood, Wimbledon Park, closely followed by Mr. A. Nevill, Sir Ed. Saunders' gr. at Fairlawn, Wimbledon Common.

Several classes for trained plants of Chrysanthemums were moderately contested. The most satisfactory were twelve plants of Chrysanthemums on single plants of Japanese varieties, in 6-inch pots, for a special prize offered by Mr. McLeod. They were shown by Mr. John French, gr. to Mrs. Barclay, Ambleside, Wimbledon Park.

Cut Blooms.—In the commemorative class for sixty cut blooms, distinct, inclusive of thirty-six Japanese, twelve incurved, and twelve Japanese incurved, there were three exhibitors; and the Challenge Cup and £4 was won by Mr. G. Hunt, gr. to Pantia Ralli, Esq., Ashstead Park, Epsom, whose exhibit was not only the best ever staged at Putney, but was remarkable for a really exceptional bloom of Mrs. R. Jones, which bore a very great resemblance to Mrs. Blick. This bloom was awarded the prize offered for the premier Japanese flower in the show. Other first-class blooms were those of J. Bidencope, Duchess of Wellington, Vicomtesse R. de Chazelles, Western King, Nyanza, Oceana, Madame Carnot, Simplicity, A. H. Wood, and M. Chenon de Leché. Of incurveds, the best were Golden Empress, Duchess of Fife, C. H. Curtis, Lady Dorothy, and Hero of Stoke Newington. Mr. J. French was a good 2nd, and Mr. Chas. Smith, gr. to W. Addison, Esq., Norbton Place, Kingston, 3rd.

The best exhibitor of twenty-four blooms of Japanese varieties was Mr. Jas. Portbury, Ripon House Gardens, Putney Heath; followed by Mr. J. Dark, gr. to J. Noakes, Esq., Lombard House, Putney; Mr. Jas. Portbury again winning for twelve Japanese blooms, distinct. Generally the Japanese blooms were fine in quality, and superior to those of incurveds.

Mr. Jas. Portbury won the classes for twenty four blooms and for twelve blooms of incurveds.

Mr. J. Wright, gr. to H. A. Tuffnell, Esq., The Grove, Wimbledon Park, won for six blooms of incurveds, six blooms of Anemone-flowered, six blooms of reflexed varieties, and for twelve bunches of Pompons.

The best single flowers were from Mr. E. Pearce, gr. to W. S. Page, Esq., The Limes, Putney.

There were minor classes for Chrysanthemums, and for Ferns, table plants, Primulas, berried plants Cyclamens, and florists arrangements. A moderate amount of good fruit was staged in competition, and the vegetables were satisfactory.

Miscellaneous.—Of non-competitive exhibits, a large group of choice plants from Messrs. Jas. Veitch & Sons, Ltd., Chelsea, was the best. There were others from Mr. R. Neal, Trinity Road Nurseries, Wandsworth; Mr. Geo. Stevens florist, Putney, &c.

PEOPLE'S PALACE HORTICULTURAL.

NOVEMBER 11, 12, 13.—The Chrysanthemum show was held in the spacious Queen's Hall, and the entries were very numerous, showing there is a considerable extension of Chrysanthemum culture in the East of London, while the quality of many of the plants and blooms was remarkable.

In what is known as the open districts—which embrace the less crowded parts, there were ten entries for six plants, and ten for two plants, eleven entries for twelve blooms of Japanese, and the same number for six blooms and ten for four. Incurred flowers were not so numerous, but excellent blooms were staged. Pompons are grown in the East, for there were eight entries of six bunches. Groups of 18 and 12 feet were also well shown. Not less satisfactory was the entries from the congested districts. There were ten entries of three plants, and eleven for two, ten of six blooms of Japanese, nine of four, fifteen of two white, fourteen of two yellow, and twenty of two of any other colour. The groups were placed round the sides of the hall; the cut blooms on long tables, the plants filling up the centre of the hall. It is satisfactory to note that the society is strong enough to make an exhibition without the help of much in the way of outside contributions.

Mr. J. H. WITTY, Nunhead Cemetery, had a fine group of plants, to which the Silver gilt Medal of the society was awarded; and in the evening Mr. Witty addressed the members on the culture of the Chrysanthemum. A group of plants came also from Mr. Kenyon, gr. to T. C. HILL, Esq., Monkham, to which a Silver Medal was awarded. Collections of very fine cut blooms came from Mr. W. BAXTER, Woking Village; Mr. G. Reynolds, gr. to the Messrs. DE ROTHSCHILD, Gunnersbury Park; and Mr. J. B. RIDING, nurseryman, Chingford.

WINDSOR CHRYSANTHEMUM

NOVEMBER 12.—A capital exhibition was held on the above date in the Albert Institute. The entries much exceeded those of last year, while the exhibits themselves showed marked improvement.

Groups of Chrysanthemums in the open class numbered five, and there was a like number in the class devoted to amateurs. In the former, Mr. Wm. Cole, gr. to Mrs. E. B. FOSTER, Clewer Manor, was ahead of his opponents, with plants well suited for the purpose, being dwarf in growth, and carrying exceedingly fine blooms. The arrangement was satisfactory and free from crowding; Mr. Bunce, gr. to WINKLEY SMITH, Esq., was a good 2nd.

In the amateurs' division, a similar award was made in favour of Mr. EDWARDS; the 2nd position being occupied by Dr. WYBORN, both staging really excellent plants and blooms.

Specimen trained Chrysanthemums were best staged by Mr. W. COLE also, who had good freely-flowered plants.

In a special class for one untrained plant, Mr. F. J. PAUL, gr. to Mrs. BROWNING, staged one of C. H. CURTIS fully 7 feet in diameter, wonderfully blossomed.

Cut blooms were staged numerous and well. The principal class was for thirty-six, half of them incurred and half Japanese. Mr. STENT, Round Oak, was a somewhat easy 1st, with full, handsome blooms in the Japanese, and fairly good ones in the incurred sections. Mr. Lane, gr. to Miss A. G. RIDGE, Ascot, was a good 2nd.

Mr. STENT was again successful in the class for twelve incurred, and a like number of Japanese blooms, exhibiting well in both sections; Mr. LANE was again 2nd.

The best twelve incurred blooms were staged by Mr. F. J. PAUL; they were not large, but of good quality; Mr. J. WILLIAMS, gr. to F. RICARDO, Esq., 2nd.

Mr. STENT staged exceedingly fine blossoms of C. H. CURTIS in the class for six incurred blooms of any one variety.

Japanese blooms, twelve varieties, were best shown by Mr. J. WILLIAMS.

Anemone-flowered varieties made a capital display. Mr. W. COLE staged handsome examples of these interesting flowers; Mr. J. WILLIAMS was a close 2nd.

Two interesting classes were provided for Chrysanthemums in vases, associated with other foliage. The principal class was that for twelve blooms with stems not less than 12 in. long. Mr. WOOD won the leading award with good blooms, agreeably intermixed with suitable foliage.

A basket or vase of cut Chrysanthemum blooms, suitable for table decoration, open only to ladies, was won by Mrs. YOUNG, with a capital basket of suitable blooms.

Fruit and vegetables made a good display. Mr. TITT had an interesting exhibit of wreaths, crosses, and other floral decorations.

WELLINGBOROUGH CHRYSANTHEMUM.

NOVEMBER 12, 13.—Wellingborough held its thirteenth annual exhibition on the above dates. The exhibits in cut blooms and groups were considerably more numerous than at any previous show held here. The society is to be congratulated for this enterprise.

For the best group of Chrysanthemums, Mr. WARD was placed 1st; and Mr. LUTON 2nd. Mr. WARD also had the best exhibit of six plants, and the finest specimen plant.

In the class for twenty-four cut blooms, Mr. J. Fulford, gr. to Mr. STOPFORD SACKVILLE, Drayton House, was 1st; and Mr. KIRBY, 2nd. Mr. KIRBY had the best twelve incurred blooms; and Mr. HAYES took 2nd prize.

For twelve Japanese, Mr. SHEPHERD was 1st, also for twelve white Japanese.

Messrs. H. R. & W. LACK, of Wellingborough, showed the best Primulas. Mr. HAYES had the best bouquet; and Mr. DOUGLAS the finest wreath.

Apples, Grapes, and Pears were shown, the chief winners being Messrs. CLAYTON & SONS, Mr. HAYES, Messrs. LACK & Co., and Mr. DOUGLAS.

Mr. HAYES also had the best vegetables.

The Society is in a flourishing condition, and subscriptions have been forthcoming very freely this year.

SHIRLEY AND SURROUNDING DISTRICTS GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT ASSOCIATION.

NOVEMBER 13.—The monthly meeting of the above society was held at the parish room, Shirley, Southampton, on the above date. There was a very good attendance, presided over by Mr. B. LADHAMS, F.R.H.S. Mr. SHRIVELL, F.L.S., Tonbridge, gave a lecture on chemical manures for the garden, and his remarks were the result of four years' experiments carried on at Tonbridge, by himself and Dr. BERNARD DYER. The conclusion arrived at seems to point out that the most economical use of manures is a combination of chemical and stable manure, in proportions and kinds suitable to the crop to be grown. A large number of questions were put to Mr. SHRIVELL on the important subject, and at the close of the discussion, a hearty vote of thanks was accorded to him. There was a large display of Chrysanthemums made by the members.

IPSWICH CHRYSANTHEMUM.

NOVEMBER 16.—The Ipswich Chrysanthemum Society is to be congratulated on the great improvement in all departments, for plants, cut blooms, fruit and vegetables were shown of the highest quality.

Cut Blooms.—Thirty-six Japanese, distinct, 1st, Mr. Messenger, gr. to C. H. BERNERS, Esq., Woolverstone Park, Ipswich, staging fine fresh blooms of—Back row: Madame Carnot, Phœbus, Australis, Simplicity, E. Molyneux, Modestum, Mrs. H. Payne, Madame Moulin, International, C. Davis, Snowdon, Silver King. Middle row: M. Chenon de Leché, L'Isère, Etoile de Lyon, M. Pankoucke, Graphic, H. H. Spenser, Madame G. Henry, Duke of York, Amiral Avellan, Western King, G. C. Schwabe, John Seward. Front row: T. Wilkins, Madame E. Capitant, Mrs. C. Blick, Mons. Gruyer, Triomphe de St. Laurent, Mutual Friend, Vivand Morel, Salim, Mrs. H. Weeks, Mrs. F. Bevan, J. Brookes, Rose Wynn. 2nd, Mr. R. C. Notcutt, Broughton Road Nursery, Ipswich, amongst his best blooms being Australis, Silver King, Mons. Chenon de Leché, Mrs. C. H. Payne, Matthew Hodgson, Madame G. Henry, Miss E. Teichmann.

Twenty-four Japanese, distinct.—The competition in this class was exceedingly keen, chief honours falling to Mr. W. Allen, gr. to Lord SUFFIELD, Gunton Park, Norwich, who staged a capital lot of blooms, the best of them being Phœbus, Stanstead White, J. Machar, Vivand Morel, Mons. Chenon de Leché, Modestum, Mons. Gruyer, and I. Prefet Robert; closely followed by Mr. Rogers, gr. to Lord RENDLESHAM, Rendlesham Park, Wickham Market, who had fine blooms of Phœbus, Miss E. Teichmann, Mutual Friend, Vivand Morel.

Twelve Japanese distinct, Mr. ALLEN followed up his success in the twenty-four, winning with an excellent stand of bright fresh blooms; Mr. T. King, gr. to J. A. BURNES, Esq., Melton Lodge, Woodbridge, a good 2nd.

Twelve Japanese distinct, amateurs.—Mr. W. J. CATCHPOLE was a good 1st with clean, fresh blooms; 2nd, Rev. A. C. JOHNSON.

Groups of plants were a strong feature of the Show. The principal prize-takers being as follows:—Messrs. G. GILBERT, R. C. NOTCUTT, and W. J. CATCHPOLE, Esq.

Collection of cut Chrysanthemums arranged with foliage and plants.—1st, Mr. W. MESSENGER, with a tastefully arranged exhibit; 2nd, Mr. G. GILBERT.

Fruit was finely represented, the chief honours falling to Messrs. W. MESSENGER, ROGERS, and ALLEN.

Grapes, Apples, and Pears were extensively shown, of good size and colour.

Vegetables made a grand feature, of excellent quality, fresh and clean, Messrs. ROGERS and KING being 1st and 2nd respectively; nine collections were staged.

HAWKHURST CHRYSANTHEMUM.

NOVEMBER 16, 17.—The annual meeting of this Society was held in the Victoria Hall, Hawkhurst, and the committee may be congratulated on the general high character of the exhibits.

The chief prize-winners in the cut-bloom section were Mr. C. ENSOLE, gr. to Colonel PREVOST, Elford, who took 1st places for twenty-four Japanese, twenty-four incurred, twelve Japanese, twelve incurred, twelve Anemone, and twelve Pompons—a highly creditable performance. Mr. A. Feaver, gr. to R. NEVE, Esq., Ashlawn, Benenden, Kent, and Mr. H. FISCHAM, Hartley House, Cranbrook, were also prize-takers in this section.

For a group of Chrysanthemums in pots, Mr. C. ENSOLE also took the lead; while for a miscellaneous group, arranged or effect, Mr. W. Crump, gr. to the Misses GOLDSMID, Tongswood, Hawkhurst, was 1st.

In the fruit classes, Apples were splendidly shown by Mr. Cooper, The Moor, who gained four 1sts, his Peasegoof's Nonsuch being particularly noticeable.

Mr. H. Collins, gr. to H. S. ASHBE, Esq., Fowler's Park, Hawkhurst, took the lead for dessert Pears. Grapes were poor.

Vegetables are always a feature at the Hawkhurst shows, and they are staged well. In this instance, the quality was exceptionally good, the 1st prize in the professional class going to Mr. J. Knapp, gr. to T. HALL, Esq., Cranecroft, Hawkhurst.

MANCHESTER CHRYSANTHEMUM.

NOVEMBER 16, 17.—This was, in all respects, an excellent show. The cut flowers of this popular autumn flower and the plants were excellent, although we have seen more spirited competition.

An additional attraction was the group of varieties of Cotton plants which Mr. P. WEATHERS put up on the area beneath the orchestra, which, in a centre of cotton commerce, was keenly scanned. The Orchids, too, were a choice lot, and included the best of golden Cypripediums, Mr. BALL taking a Gold Medal for the six flowered plants that he showed at the Orchid meeting at the Coal Exchange, and again at the Drill Hall in London. In so far as Orchids were concerned, it was remarkable for a choice display.

CHRYSANTHEMUMS

were limited in number as regards pot plants, but the quality of the blooms was very marked. Mr. J. H. GADGUM, Didsbury; Mr. T. HARKER, Fallowfield; Mr. BEHRENS, Mr. GOODACKER, Elvaston; Mr. WATTS, Cheadle; and Mr. J. STANNING, Leyland, were principal exhibitors.

The cut flowers were very good, especially those in the stands of Mr. BEHRENS, Mr. PENNINGTON, Mr. GREENHALGH, Bolton Dene; Mr. STATTER, Miss LORD, and Mr. W. B. EDMONDSON. The exhibitors were not so numerous, but the quality of the exhibits stood out prominently.

ORCHIDS.

Some excellent mountain-grown Cypripedium insigne came from Mr. LEWIS, and a rather striking seedling of Calanthe vestita alba, large flower, and an albino. Mr. CYPHER had lots of good things which we cannot, with the limited space at disposal, enumerate.

The attendance was in all respects satisfactory, and the second day promises a bumper gathering. Great credit is due to the indefatigable Curator, Mr. WEATHERS; and such efforts put forth are sure to tell for the future finances of the Royal Botanic Garden.

THE NORTH PECKHAM AMATEUR CHRYSANTHEMUM SOCIETY.—Our readers may well ask, in dubious tones, "Is the Chrysanthemum craze really coming to an end?" after perusing the following letter, sent by the enthusiastic secretary of the North Peckham Amateur Chrysanthemum Society, Mr. WILLIAM NICHOLS:—"We had a grand show this year, over 200 entries, splendid blooms, and more than 4000 visitors; the value of the prizes was about £100, Messrs. W. EARLY and MEASE were the judges. I have for next year, now on view in the High Street, Peckham, three large and valuable marble clocks, also cheques to the value of £8 whereby to purchase the objects of art to be offered as prizes in 1898 for plants grown with a special manure. I can assure you, I intend, if it be at all possible, to make it next to the National Chrysanthemum Society. I was an old member of that society for many years; and a friend of the late W. HOLMES. You can see what our prizes were by the enclosed prize-list. [Most miscellaneous, forty in all. Ed.] We have altogether 200 members—not bad in three years; and when we extend it, of course, there will be many more. The radius of our operations is only about three-quarters of a mile; it is therefore not wise to commence in a large way at first."

NATIONAL CHRYSANTHEMUM.—At a meeting of the Floral Committee on the 15th inst., First-class Certificates of Merit were awarded to Mdlle. Lucie Faure, a large white incurred, full deep, highly promising, from Mr. W. J. Godfrey, Exmouth. To incurred Japanese Mdlle. Lawrence Zede, pale lilac-pink with light centre, of the build of Mrs. C. H. Payne, large and full; and Earlwood Beauty, a large white single variety with somewhat drooping tubular petals, from Mr. W. Wells, Earlwood, Redhill. To Japanese Mrs. G. Carpenter, pale bright lilac-purple with silvery reverse, and long curling basal petals, a fine exhibition variety, from Mr. G. Carpenter, West Hill, Byfleet. To incurred Ernest Cannell, a fine full flower of a soft buttery-cream colour, excellent in build and petal, from Mr. R. Leadbetter, Elmstead Lodge, Chislehurst. To Japanese Master

H. Tucker, a very fine flower, bright golden amyranth on the surface, with bronzy-gold reverse, from Mr. H. Shoemith, nurseryman, Woking. Commendations were given to incurred Madame Ferlat, a large white, much in the way of Mdlle. Lucie Faure, from Mr. W. Wells; also to Japanese General Roberts, in the way of Eva Knowles, not so good as shown, but yet promising, from Mr. J. Ollerhead, Wimbledon. Several very promising varieties the Committee wished to see again. A small Silver Medal was awarded to Mr. William Wells for a collection of new Chrysanthemums.

SCOTTISH HORTICULTURAL.

NOVEMBER 18, 19, 20.—The annual Chrysanthemum exhibition held by this Society of three days' duration, was opened on Thursday, November 18, in the Waverley Market, Edinburgh. This year's exhibition is undoubtedly the largest of its kind ever held in Scotland, and this may be accounted for by the special efforts of the Council to commemorate the Diamond Jubilee of Her Majesty's Reign, the incentive to a large exhibition, and strong competition being offered by the Society in prizes of large value; especially is this the case in the Diamond Jubilee prizes, open to all gardeners and amateurs. This has brought eleven entries, the competition being exceedingly keen.

Other prizes, both ordinary and special, have also brought forward strong competition, in some classes in the cut flower section the entries number over thirty; while among vegetables, always splendidly shown, at Edinburgh over fifty names are entered.

Over twelve hundred and fifty entries are made for the entire show, and so hard have the council been pressed for space by intending exhibitors, that even in such a splendidly adapted and spacious structure as the Waverley Market many nurserymen exhibitors have been unavoidably declined space.

This speaks for itself in regard to the success of the Show. On usual occasions the non-competitive exhibits staged by nurserymen have been needed to give the market a furnished appearance. Since the installation of the electric light, the light thrown over the whole of this large building has been greatly improved, and a good view is everywhere obtainable. The market, as usual, is tastefully draped and decorated by Messrs. Cranston & Elliot. The Council and different sectional committees have been severely taxed, but their arrangements have been satisfactorily carried out, while the efforts of the Treasurer, Mr. A. Mackenzie, and the energetic secretary, Mr. R. Laird, have been considerable. The opening ceremony was suitably performed by Mr. Thomas Gibson Carmichael, and presided over by the Right Hon. Mitchell Thomson, Lord Provost of Edinburgh. As the surplus proceeds from the exhibition are to be devoted to local and horticultural charities, it is hoped these will be as generous as the objects merit.

Twenty vases of Chrysanthemums in twenty varieties, true blooms of each Chrysanthemum foliage only to be used. The Grand Victoria Jubilee Prize of £50 in cash and Victorian Gold Medal, was won by Mr. A. Haggart, gr. to Hon. Lucius Brien, Moor Park, Ludlow, with a grand lot of the following varieties, Western King, Chas. Davis, Graphic, M. Grayer, Implicity, Jas. Biddenscope, M. Pankoucke, M. D., A. D. batin, Mrs. H. Cross, Edith Tabor, Lady Ridgway, Etolle a Lyon, Niveum, Mrs. W. H. Lees, M. Chenon de Leché, Tabordier, Australian Gold, Mrs. H. Weeks, Vivand ore, and Richard Dean; the 2nd prize of £30 and Victorian Silver Medal was won by Mr. W. H. Lees, gr. to W. BEVAN, sq., Trent Park, with a very fine and bright fresh lot, but a quite so heavy as the 1st prize lot; 3rd prize of £15 R. McHATTIE, Strathfieldaye, Wauke; the 4th prize of £10, Mr. P. WATERER, Fawkham, Kent; 5th prize, £8, Mr. BLAIR, gr. to Trentham Park; 6th prize of £7, Mr. W. DIVERS, . Belvoir Castle.

City of Edinburgh prize of £25, for forty-eight cut blooms, unique, distinct; Mr. HOGGARD was again 1st, with Mrs. aling Grant, Mr. W. H. Lees, Dorothy Seward, Mr. H. C. lyne, Miss Maggie Blinkiron, M. Ricoud, Madame A. olin, H. L. Sunderbruck, Pride of Wadford, Simplicity, . Chas. Molin, John Seward, A. H. Ward, Phobus, M. scribe Rey, Chas. Davis, Niveum, Duke of York, Moor rk, Australian Gold, Etolle de Lyon, Lady Ridgway, r. H. Weeks, M. A. de Galbert, Chenon de Leché, Western ing, G. C. Schwabe, Hermann Kloss, M. Ad. Chatin, ichard Dean, Australia, Mr. F. A. Bevan, C. Mely, J. idenscope, Dorothy Shea, C. W. Richardson, Madame Carnot, eans, M. Montigny, Internati nal, Modestum, Van den eede, Vivand Morel, Rose Wynne, Mons. Pankoucke, Mr. r. Ironides, Edith Tabor, and Mutual Friend. 2nd, Mr. J. EWART, gr. to Castle Huntly, Longforan. 3rd, Mr. J. ORDYCE, Bonall Tower, Colinton. 4th, Mr. D. NICHOLL, oowie, Forquandenny. 5th, Mr. R. ADDISON, Black House, telmorlie. There were ten entries in this class.

Seventy-two Vases Japanese Blooms in as many varieties.— Old Victorian Medal offered by the Scottish Horticultural association and five pounds in money, was won by Mr. R. W. MURRAY, Blackford House, Edinburgh; 2nd, Mr. D. ehol, gr. to J. W. BELL, Esq., Rosale; 3rd, Mr. J. FOSTER, ellwood Park, Selkirk.

Twenty-four Incurred.—1st, Mr. J. MARTIN, Corndean Hall, Winchcombe; 2nd, Mr. J. McHATTIE; 3rd, Mr. P. BLAIR.

Twelve Incurred.—1st, Mr. W. H. Lees, with a nest stand; 2nd, Mr. J. MARTIN.

PLANTS.—The number of specimen plants was far in excess of previous years, huge well-flowered specimens being generally shown. The judges for this section of the show were Mr. Fraser Smith, Cullen House, Cullen, and Mr. George Hay, Garvald House, Dolphinton.

In the class for six pot-plants, distinct varieties, Mr. D. CAVANAUGH, St. Edward's, Murrayfield, was 1st, with a finely-flowered, even collection of plants; 2nd, Mr. JOSEPH HOLMES, Winton Castle, Pencoatlant.

For six Pompons, Mr. P. HUNT, Colbridge Hall, Murrayfield, secured 1st place for huge specimens generally; the varieties Nellie Rainford and Rosinante were particularly good. Mr. W. FULMAN, Holly Wood, Colinton Road, was 2nd with smaller specimens.

Mr. D. CAVANAUGH also secured 1st for six Japanese varieties, among eight entries, with superb plants; 2nd, Mr. W. BENNETT, Hanley Gogar.

For two distinct pot plants, Mr. J. HOLMES was again 1st. The best single orange-coloured Chrysanthemum came from Mr. CAVANAUGH, the variety being President Lincoln. The same exhibitor secured 1st places in the classes for both bronze and crimson-flowered varieties. Mr. ABBOT, with a good specimen of Madame de Senn, was 1st for a single specimen of a purple-flowered variety. The Pompon from Mr. J. WALDIE, Dollarbag, Dollar, was capital, and 1st among the eight competitors.

The 1st prize in the class for the best pot plant competition limited to gardeners and amateurs, was awarded to Mr. D. CAVANAUGH, for a grand specimen of Vivand Morel. The best plant of Pompon Rosinante was sent by Mr. P. HUNT, Colbridge Hall.

In the amateurs' class, the prize for the best plant was gained by Mr. A. HOGG, Newtown, Pencoatlant, and was awarded a Silver Medal. Mr. Hogg was also 1st for the best white-flowered Chrysanthemum, the variety being Avalanche.

Three groups were arranged for effect, the successful 1st prize group having been arranged by Mr. G. Wood, gr. to Mr. BUCHANAN, Oswald House, Edinburgh; 2nd, Mr. Jardine, gr. to Miss MURRAY, Gartshore, Ravelston; 3rd, Mr. P. HUNT, Colbridge Hall.

In the class for Palms confined to Nurserymen, Messrs. R. B. LAIRD & SONS were the winners of the 1st prize, for six plants in pots of 9-inch diameter, and for four plants in tubs.

For eight plants in 16-inch pots or tubs, Messrs. DOWNIE were 1st. In the class for eight decorative plants Mr. MACKAY, Kingston Grange, Liberton, took leading honours.

FRUITS.

Grapes were well exhibited; the bunches and berries being large and well coloured. The best four distinct varieties came from Mr. D. AIRDRIE, Larbert House, Larbert, the Muscats and Gros Marocs deserving special note; 2nd, Mr. G. PATERSON, Benochill Park, Kirkcaldy. For two bunches Mr. T. LUNT, Keir House, Dunblane, was 1st; 2nd, Mr. J. MACNEILL, Priorsford, Peebles. Mr. T. LUNT also secured 1st prize for Muscat of Alexandria with excellent bunches of well-ripened fruit. In the class for Alicantes, Mr. J. LESLIE, Pitoullan House, Perth, was 1st.

The best collection of Eight Dishes of fruit was from Mr. MCINTYRE, The Glen, Innerleithen, with specially good Grapes, Pears, Apples, and Melons. For two Smooth Cayenne Pines this exhibitor was also 1st. Mr. W. LAING, Wellfield, Gateside, was 1st for six Pears grown in Scotland. For six varieties of Pears, Mr. T. THOMSON, Cherry Trees, Kelso, was 1st. For six dessert Apples, Mr. J. DAY, Galloway House, Garscadden, was 1st; Mr. J. CAIRNS, Coldstream, 2nd. Mr. J. DAY was also 1st in the class for eighteen varieties of Apples, and Mr. J. CAIRNS was 2nd.

VEGETABLES.

The best collection of vegetables, consisting of ten distinct kinds were from Mr. W. HARPER, Tulliebelton House, Perth. His was a splendid lot; and Mr. A. C. CAMERON, Binnock, Dundee, was 2nd; and Mr. J. WALDIE, Dollarbag, Dollar, 3rd, among twelve competitors.

For a collection of six kinds, the 1st prize was won by Mr. A. C. CAMERON; 2nd, Mr. A. DIXON, Glenormiston, Innerleithen; and 3rd, Mr. J. WALDIE.

Leeks, Brussels Sprouts, Cauliflowers, and Tomatoes, were very strongly contested. Several dishes of Peas were noticeable in the collection.

NURSERYMEN'S EXHIBITS.

Mr. JONES, Eyecroft Nursery, Lewisham, staged a lot of Begonia Gloire de Lorraine, which were models of good culture, and formed one of the principal features of the show; many superb varieties of Chrysanthemums; and finishing off a grand exhibition stand of blooms of Chrysanthemum Western King that were specially fine.

Messrs. DOBBIE & Co., Rothessay, had a number of varieties of Chrysanthemums and Potatoes, a new variety named The Crofter, a late round form of clean appearance being amongst them.

Messrs. THOMPSON & SONS showed Grapes, Tomatoes, and Plants.

A stall in aid of the Gardeners' Orphan Fund, to which we wish every success, was a feature of the show.

TRADE NOTICE.

MR. H. A. BURBERRY.

It will be interesting to many to learn that Mr. H. A. Burberry, for many years chief Orchid-grower to the Right Hon. Joseph Chamberlain, and author of *The Amateur Orchid-cultivator's Guide-book*, has resigned his post, and commenced business as a consulting expert on all matters pertaining to Orchids. Seeing that some or other of the plants in a large proportion of our Orchid collections are often ailing, and considering the value of many of the subjects so affected, it should be a relief both to their owners and their growers to have a man of such experience and skill to call in and advise with them. Apart from any question of superior skill, it is a known fact that an experienced man called in for the occasion, often detects the cause of failure, which, in consequence of daily familiarity with the surroundings, had not been evident to those in charge. We wish Mr. Burberry every success.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 45° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Graving, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending November 13, is furnished from the Meteorological Office:—

"The weather during this period became very unsettled, with frequent and heavy rain in the western and north-western districts. In the east and south-east, however, the conditions were comparatively dry, although slight rain occurred during the early days of the week. Fog was experienced from time to time over England, and much cloud prevailed.

"The temperature was much above the mean, the excess ranging from 4° in 'England, E.' to 6° or 7° in all the western districts, and in 'Scotland, N.' and to 8° in 'Scotland, E.' The highest of the maxima were recorded during the latter half of the week, and varied from 63° in 'England, N.W.', and 61° or 60° in most other districts, to 58° in 'Scotland, N.', and 57° in

'Scotland, W.' The minima were, as a rule, very high for the time of year, but were relatively low in many places both at the commencement and towards the end of the period. The absolute minima ranged from 29° in 'England, E.', 31° in the 'Midland Counties,' and 32° in 'England, S.W.', to 40° over Ireland, and to 43° in the 'Channel Islands.'

'The rainfall was again less than the mean in all the Wheat-producing districts, and in the Channel Islands. In the western and extreme northern parts of the kingdom, however, there was an excess, that in 'Scotland, W.', and in 'Ireland, S.', being very large.

'The bright sunshine was much below the normal, especially over Great Britain. The percentage of the possible duration ranged from 22 in 'Ireland, S.', and 21 in the 'Channel Islands,' to 6 over 'Scotland,' to 2 in 'England, E.', and to 1 in 'England, N.E.'

MARKETS.

COVENT GARDEN, NOVEMBER 18.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

SEEDS.

LONDON: November 17.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report an inactive and uninteresting market. Business in Clover-seeds is, for the time of year, unusually meagre. Winter Tares, owing to the continued speculative demand, and the attractively low price, are getting into narrow compass. Rye keeps steady. Full values are asked for Mustard and Rape seed. The Linseed trade is quiet. Blue Peas and Haricot Beans command late rates. As regards bird seeds, transactions are at present limited, both in number and extent. The Board of Trade Returns give the imports of Clover and grass seeds into the United Kingdom for the ten months ending October 31, 1897, as 220,051 cwt., value £432,918, as against 317,708 cwt., value £690,350, for the corresponding period of 1896.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending November 13, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

Will some Chrysanthemum specialist or reader of *Gardeners' Chronicle* kindly advise me as to the best time to stop the following varieties to secure the buds at the right time to produce first-class blooms from three to six on a plant, and also if any of them need specially potting, and also the time to put in cuttings in cold greenhouse—

INCURVES.	JAPANESE.
C. H. Curtis	Mme. Carnot
Globe d'Or	G. C. Schwabe
J. Agate	Vivian Morel
Lord Alcester	Charles Davis
Queen of England	Green Chrysanthemum
Robert Cannell	Duchess of Wellington
John Lambert	Silver Cloud
Mrs. Robinson King	Val de Andorre
Baron Hirsch	Annie Clibran
Mrs. W. Shipman	Noces d'Or
Mrs. G. Rundle	Mona, C. Molin
	Louisa
	International
	J. P. Kendall
	Mme. Thés. Roy
	Thos. Wilkins
	Mme. Marie Hoste
	White Louis Bohmer

J. R. A.

An authority on the cultivation of Chrysanthemums, replies as follows:—"At the outset, I would say no method of treatment will enable a cultivator to produce first-class blooms of some of the varieties named on the list referred to, at least, if exhibiting is a point of consideration. Varieties like Mrs. G. Rundle in the incurved section, Val d'Andorre, Annie Clibran, and White Louis Bohmer in the Japanese, are now much too small to take even a third-rate position in strong competition. It is wise to have more than one plant of a sort, manage one on the topping principle, the other on what is known as the natural method of cultivation, viz.: Allow the latter to grow away uninterruptedly until the first natural break occurs in March, April, or May, as the case may be. In both methods of culture, insert the cuttings early in December, which enables the plants to grow away slowly, so that the growth has ample time to mature; without maturity, it is useless to expect blooms of high quality. As to topping the plants, the first or second week in April is the most suitable period. Topping, however, so much depends upon the state of the plants that it is difficult to advise. If they are weakly, they of course are not so amen-

able to treatment of a special nature as those of stronger growth. Another point: six blooms on a plant is rather too many to produce blooms equal to what is obtained when three are grown on a plant, especially of the large growing varieties."

* * Owing to the pressure on our space, several reports of Chrysanthemum and other shows are held over till our next issue.

BOUVARDIA DISEASE: C. B. W. Too well known in its results, but, we are sorry to say, the cause and cure are alike doubtful.

CHRYSANTHEMUM FUNGUS: Jas. C. The worst case we have yet seen of "rust," due to a species of fungus, Uredo. This pest threatens to become a most troublesome one, many of our correspondents having lately favoured us with affected specimens. If you will refer to *Gardeners' Chronicle*, Oct. 9, p. 256, and Oct. 23, p. 294, you will find the pest described, and the possible measures of prevention discussed.

CHRYSANTHEMUMS, NEW: A. C. You should send a specimen to the meeting of the Floral Committee of the Royal Horticultural Society, or of the National Chrysanthemum Society. Meetings of the latter body will be held on November 22 and 29, and December 7 and 13 at the Royal Aquarium, Westminster.

CITRUS TRIFOLIATA: Westwood. This plant may be obtained at Messrs. J. Veitch & Sons' nursery, King's Road, Chelsea, London, S.W.

CYPRIPEDIUM: H. J. R. The hybrid *Cypripedium* sent seems to be a variety of *C. x Alcides* (*hirsutissimum* x *insigne*) described in the *Gardeners' Chronicle*, January 10, 1891, p. 40. A plant of it was shown at the Royal Horticultural Society's meeting on November 9.

FOREIGN FRUIT—CACQUIN, OR CAQUISE: Caquique. We know of no fruit under this name, although etymologically the name given is similar to the French *Coignassier*—Quince.

NAMES OF FRUITS: P. A. W. 1, Northern Greening; 2, Warner's King; 3, Golden Noble; 4, Shepherd's Newington; 5, Byson Wood Russet; 6, Adams' Pearmain.—J. Lawrie. 1, Tower of Glamis; 6, Bess Pool; 7, Reineette du Canada.—Q. R. Tower of Glamis.—C. R. 1, Beauty of Kent; 3, Rosemary Russet; 4, Dutch Mignonne. From the other three fruits the labels had become detached.—Judo. Your specimens of Pears are much too overripe.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—J. & Co. Saintpaulia ionantha.—P. C. P. 1, Berberis Darwini; 2, Veronica variegata; 3, V. Traversii; 4, Diosma ericoides; 5, Elaeagnus pungens.—J. Nat. 1, Pteris tremula; 2, Cyperus alternifolius; 3, Adiantum capillus-veneris; 4, Asparagus decumbens of gardens; 5, Adiantum cuneatum grandiceps; 6, Dracena intermedia.

PATENTS: Z. A. Make personal application at the Patent Office to register your patent, which you will be allowed to do if it has not been anticipated.

SINGLE CHRYSANTHEMUM: R. M. It is a very pretty white bloom, but hardly fresh. It is curious as a sport from the variety you name, a circumstance we should never have guessed.

Gardeners' Chronicle.

SATURDAY, NOVEMBER 27, 1897.

THE HYACINTH IN 1768.

NOW that the planting of this ever-popular spring flower is in full force, attention may, not inappropriately, be called to one of the most curious and exhaustive treatises on the subject ever published. I refer to *Des Jacintes, de leur Anatomie, Reproduction, et Culture*, which appeared in French at Amsterdam in 1768. The name of the author is not given in the work; but from other sources we learn that it was written by the Marquis M. H. de Saint Simon. The book extends to 164 pages quarto, in addition to ten beautifully-engraved full-page plates, and several lists of varieties at that time under cultivation. The compilation was clearly a work of love on the part of the author, for, within its proper limits, no phase down even to the minutest detail is omitted.

The Hyacinth, he tells us, is of all flowers that which presents the most agreeable diversity in all its aspects; its form, its height, its colours, and even its odour more or less varies in all its forms, of which, at the time of writing, there were nearly 2000 cultivated at Haarlem. The author speaks in a somewhat suppressed style of enthusiasm of the extreme beauty of Haarlem when these flowers are in their full beauty — “l'imagination ne se forme qu'un tableau très-imparfait des graces et de la variété de ce brillant émail.” This effect is not attained without great forethought and consideration, for their successful culture involves special and uninterrupted attention, constant work, and the display of much taste, all of which are, of course, greatly aided by the congenial soil and climate of Haarlem.

Nothing is known for certain of either the colour or the origin of the first Hyacinth. It is, like its name, probably of oriental extraction. Some authors trace its earliest mention to the *Book of Exodus*. We may conveniently leave the *surants* to fight out amongst themselves the history of the Hyacinth, so far as regards the references, real or imaginary, to it in the ancient classics. In connection with the original colour, there is a very general agreement that this was blue, as this colour is found indigenous to most of the European woods, the form having red flowers being comparatively rare. The Marquis de Saint Simon is of opinion, however, that the red is the type from which all the thousands of varieties have sprung, and he advances many excellent reasons and authorities for such a theory. The author does not waste much space in discussing points which are, after all, of very little consequence

from a practical point of view. It is of far greater importance to know the physiology of the bulb itself, and it is into this phase of the subject that the author enters with a minuteness almost bewildering. An entire chapter is devoted to the outward “signs and tokens” of good, sound, and healthy bulbs.

The next chapter, a long one of ten pages, deals with the “racines” of the Hyacinth, that is, the roots thrown out by the bulb. The author comes to the conclusion, after microscopic and other investigation, that these “racines” are “vaisseaux excrétoires et non des pompes aspirantes.” He points out that in many instances the bulbs have been found to flower without these racines, citing in particular one of the earliest, and perhaps one of the poorest in quality, the variety “de Janvier,” which throws out its flowers without the aid of either earth or water. The “racines” of the Hyacinth do not resemble any other analogous organs in plants or trees. In the pursuit of his investigations, the author placed a number of bulbs in glasses with water adulterated with carmine, gum, prepared verdigris, indigo, Prussian blue, cochineal, Indian ink, madder, and oil, and yet for the most part the roots were duly found on the flower developed; whilst in other cases the roots have been thrown out whilst the flower itself has been manifestly injured. A good deal of space is devoted to those very interesting experiments, into which it is scarcely necessary in this place to enter fully. A single chapter is devoted to a consideration of the scales or outer covering which preserves and nourishes the rudimentary flower; another to the suckers or offshoots, and another to the seeds of the Hyacinth.

The latter chapter contains a few interesting facts about the double-flowered Hyacinth. A century ago (i.e., a century before the year 1768) the double form was neither cultivated nor known. Swertius, in his *Florilegium*, printed at Arnheim in 1620, gives figures of about forty varieties or species of Hyacinth, all of which are single. The first double variety was a seedling which appeared in the gardens of Peter Voorhelm (whose business was still carried on at the same place by his grandson, George Voorhelm, when Saint Simon wrote his book), at Haarlem. At that time, the exact date is not certain, but it was probably towards the latter part of the seventeenth century, all the bulb growers waged incessant warfare against all Hyacinths raised from seeds or offshoots bearing flowers which in any way did not conform to the conventional notions of a perfect flower. The idea of a double variety does not appear to have entered even into the dreams of the Dutch florists. But (and the story reads almost like a page out of Dumas) Peter Voorhelm was taken ill, and could give no attention to his plants, and was unable to examine them until the Hyacinths were beginning to die off. A flower of unusual form arrested his attention, and examination proved it to be a double Hyacinth; it was very small, but he cultivated and multiplied it, and was soon able to place it on the market, whilst numerous amateur growers were found willing to pay high prices for the new bulb. The *editio princeps*, if it may be so

termed, of the first double Hyacinth had a comparatively short life, for it was lost long before 1768. The two second double varieties discovered subsequently were named, respectively, Marie and the Roi de la Grande Bretagne, the latter obviously in honour of Dutch William. The latter was raised about 1698, and was infinitely the finest of the first three varieties, and over a thousand florins was paid for a single bulb. It thrived exceedingly in climates warmer than that of Haarlem; in colour it was white mixed with red.

The consideration of the anatomy and generation of the Hyacinth forms perhaps the most important chapter in the book; certainly, it is the longest, and extends to over seventy pages. The Marquis of Saint Simon, not content with recording his own exceedingly elaborate and careful researches, completely digests all that had been previously written on the subject, English as well as foreign; even that rather shallow philosopher (whom the Marquis describes as one of the “plus sublimes des Philosophes Anglois”) Alexander Pope, is dragged into the matter! Indeed, the chapter itself might very well have been published as an independent treatise on the generation of plants, it is so all-embracing. The concluding chapter, which extends to thirty pages, deals with the cultivation of the Hyacinth, and mention is made, *inter alia*, of the “singularités” of the different varieties at that time under cultivation. Here also our author's passion for thoroughness is manifest, and his extensive inquiries and reading equally obvious.

We need not, however, stay to analyse this chapter; but he quotes a very interesting paragraph from the work of George Voorhelm, on the *Culture des Jacintes*, in which that eminently practical grower insists that amateurs may grow the Hyacinth with as great a success as the Dutch growers, if they take the same amount of trouble. Moreover, “Je finis en souhaitant qu'il se trouve encore quelqu' Amateur dont les connoissances soient plus grandes que les miennes, et s'il en est un, je le prie pour les vrais Curieux et pour moi de mettre la main à la plume.”

The penultimate paragraph deals with the experiences of our old friend “le célèbre Philippe Müller,” otherwise Philip Miller, who states, in the article on the Hyacinth in his “*Dictionary*,” that the bulbs sent from Holland in 1730, not only flowered beautifully in his garden, but that he was as successful in their cultivation as the Dutch growers.

Included, apparently as an after-thought, for the pagination is independent of the text of the book, is a most interesting catalogue of the Hyacinths known in 1767. About 1,670 varieties, double and single, are here enumerated, and it would be very interesting to know if any of them are still in cultivation. Probably not; although many of the names are familiar, it is more than likely that they are applied to new forms. Following this catalogue, comes a very interesting analysis of George Voorhelm's Hyacinth-bed in nine rows, five of which contained thirty-eight, and four of thirty-seven Hyacinths each, or a total of 338. A Hyacinth-bed of J. Kreps in six rows of forty-one bulbs each; and, finally, a bed formed by an amateur (Mr. Cock), in seven rows of thirty-seven bulbs, conclude this exhaustive monograph, which will well repay perusal by those who make the Hyacinth a special study. W. Rober

NEW OR NOTEWORTHY PLANTS.

SELAGINELLA CRUGERI, Jenm., n. sp.

FRONDS sub-prostrate, overlapping in growth, rooted at the base, and leafy thereto, dark-green, membranous, 1 to 1½ inch long, with alternate branches ½ to ¾ inch long; rachises stramineous, slender, hardly flexuose, angled when dry, branches about 1 line wide over the leaves, the primary and secondary being of nearly equal width; major leaves spreading horizontally, apart, or the outer ones contiguous, imbricating at the ends of the branches, oblong-lanceolate, ½ line long, ¼ broad, acute, inaequilateral, the upper base rounded and cordate, but not conspicuously expanded; copiously ciliate round the auricle, which overlaps the rachis; minor leaves apart on the primary rachis, but close on the outer one, slightly inaequilateral and subcordate, narrowly lanceolate, spinulose-pointed, ¼ line long; spikes flattened, 1½ line long, and nearly or quite as wide; bracts resupinate, lax, erecto-spreading, slight-ciliate-edged.

Trinidad; No. 194, *Herb. Trin.*; near S. Ottonia of Cuba. In form of frond and leaf it resembles albonitens, from which, however, it is readily distinguished by the short, flat spikes, long bracts, and freely ciliated leaves. The bracts which follow on the plane of the minor leaves are much enlarged, but those which follow the major leaves are not much reduced. Endemic. *G. S. Jenman, Demerara, October, 1897.*

THE BOTANICAL HISTORY OF THE UVA, PAMPAS GRASS AND THEIR ALLIES.

(Continued from p. 358.)

THUS we have in *G. saccharoides* and *G. argenteum*, two grasses, quite distinct in their mode of growth, and in their floral structure; one with a very marked, the other with a slightly indicated sexual dimorphism; one with a definite number of florets in each spikelet, and with a rachilla terminating abruptly with the second floret, the other with an indefinite number of florets, and with a rachilla gradually exhausting itself; one with two stamens, or staminodes, in each flower, the other with three. There may be further differences in the fruit; but I have not been able to find a single mature grain of *G. saccharoides*, as all those which I have seen proved imperfect on examination. However that may be, the differences as we know them, are certainly much more conspicuous, and much better defined, than those which separate, for instance, the allied genera *Phragmites*, *Arundo*, and *Neyraudia*. *Gynerium*, as represented by *G. saccharoides*, is, indeed, one of the best characterised and most natural genera of grasses, whilst it becomes at once vague and artificial if we allow *G. argenteum* and the other members of the group of which it is representative to remain in it. I propose, therefore, to retain the name *Gynerium* for the original species, and to exclude *G. argenteum* and its immediate allies.

The next question then is, which of the remaining species, described under the name of *Gynerium*, if any, have to go with *G. saccharoides*? The only species which come into consideration are *G. parviflorum* (Nees), and *G. arcuato-nebulosum* (Carr.). *G. parviflorum* was described by Nees from incomplete specimens collected by Martius and Prince Neuwied in Brazil. I have not seen them; but Doell, who examined the very material from which Nees drew his description, refers to it some specimens gathered by Gardner in Brazil, and by Sieber in Martinique. These were at my disposal. Yet I have been unable to find any difference between them and typical *G. saccharoides*. It is quite evident that Nees was misled by the imperfect state of the material, and that *G. parviflorum* is specifically identical with *G. saccharoides*, an opinion to which also Doell inclines. The other species, *G. arcuato-nebulosum* (Carr.), was described and figured from some panicles which had been sold in Paris for decoration; but neither the figure nor the description is sufficient to

enable the reader to recognise the genus or even the tribe. Some panicles, however, which M. Ed. André, of Paris, communicated to Kew as representing Carrière's *G. arcuato-nebulosum*, proved to be *G. saccharoides*. *Gynerium* is therefore, so far as we know, a monotypic genus; and I may add that—as the very copious material which I have seen shows—it exhibits also, throughout the large area inhabited by it, a remarkable uniformity so far as varietal differentiation is concerned. Without going into details with respect to distribution, it may suffice to remark that *Gynerium saccharoides* is a tropical plant, ranging from Southern Mexico to Paraguay and Southern Brazil, whilst the other so-called *Gyneriums* are confined to subtropical and temperate South America, or to the temperate regions of the mountains of tropical South America.

By confining the genus *Gynerium* to *G. saccharoides*, and omitting the *a priori* synonyms mentioned above, there remain still eleven species of our list for which we have to account. Two of them, *G. triaristatum* and *G. Wolfii*, Sodiro, are unknown to me; I must, therefore pass them over at present. Of the others, *G. argenteum*, Quila, speciosum, atacamenso, purpureum, roseum Rendatleri, and jubatum are so closely allied, that botanists taking a very broad view of the species would perhaps not hesitate to refer them to one species only. I will call them briefly the Cortaderas, "Cortadera" being the name by which they are generally known with the Spanish-speaking South Americans. *G. modestum* and *G. zeelandicum*, on the other hand, are doubtlessly distinct from each other, as well as from the Cortaderas. I intend, however, to confine myself in this article to the true Cortaderas, and reserve my observations on the two last-mentioned grasses for another paper.

The question is now, do the remaining species of *Gynerium* constitute a new genus by themselves, or are they referable to another already-known genus?

Gynerium argenteum was originally described as *Arundo dioeca* (Spreng., Syst. I. 361, non Lour.), and *A. Selloana* (Schult. Mant. 605); yet, as the definition of *Arundo* was then extremely vague, including grasses of very different structure, such as species of *Deyeuxia*, *Calamagrostis*, *Phragmites*, *Ampelodesmos*, *Stipa*, *Gastridium*, &c., this is perhaps of little importance, except in so far as it shows that there is a certain resemblance of *Gynerium* with *Arundo*. But what is *Arundo* in the modern sense, and in which relation do *G. argenteum* and its congeners stand to it? *Arundo*, in the sense of Benham & Hooker's *Genera Plantarum*—a conception which has been adopted by Hackel in Engler and Prantl's *Natürliche Pflanzenfamilien*, and by Baillon in his *Histoire des Plantes*—comprises four geographically distinct groups, namely, (a), one to three essentially Mediterranean species; (b), one species, ranging from India and the Malayan Archipelago to Madagascar and South Africa; (c), one or two species from New Zealand; and (d), a few species from South America.

The first group consists of *Arundo Donax*, with *A. Pliniana* (Turra) and *A. Mauritanica* (Desf.), forms which may be considered as specifically identical with *Arundo Donax*. This is the nucleus of the genus. The species referred to under (b), is *A. Reynaudiana* (Kunth), a very tall reed which Sir Joseph Hooker has shown to constitute a new genus, *Neyraudia*. The New Zealand species are *A. conspicua* (Forst.) and *A. Kakao* (Steudel)—probably synonymous with *A. fulva* (Buchanan)—which is very closely allied to *A. conspicua*, and may, in any case, be taken as identical with it for the purposes of this paper. We have seen that *A. conspicua* has been described as *Gynerium zeelandicum* by Steudel, and it agrees, indeed, in all essential points with *G. argenteum*, except that it is hermaphrodite. Apart from this sexual condition, it stands therefore in the same relation to *Arundo Donax*, as *G. argenteum*. Finally, the South American species, which the authors of the *Genera Plantarum* had in view, were *A. pilosa* (Urv.), *A. nitida* (H. B. K.), and probably some undescribed species in the Kew Herbarium. All these species are, however, dioecious, and should

therefore have been referred to *Gynerium*, in the sense of the *Genera Plantarum*. It may suffice to mention here that these South American grasses possess the same mode of growth which is characteristic of the Pampas-grass, although some of them are very much smaller, and that they differ chiefly in the structure of their valves, which are five- to seven-nerved, usually shortly acuminate, and distinctly awned, rarely mucronate.

Thus, nothing is left of the modern conception of *Arundo*, as the original nucleus, the familiar *A. Donax*, L., or the Spanish Reed; and the decision whether *G. argenteum* and its congeners are to be sunk in *Arundo*, or to be made into a new genus, depends solely on the comparison with *Arundo Donax* (in the broad sense). Taking *Gynerium argenteum* as representative of the Cortaderas, I will, as I did above, place the description of the essential characters of both grasses alongside, in two parallel columns; but as the vegetative characters of *Arundo Donax* are, on the whole, the same as those of *Gynerium saccharoides* (save the hollow culms, the smaller dimensions, and the absence of stilt branches in *Arundo*), I may refer the reader, with respect to them, to the comparative descriptions of *G. saccharoides* and *G. argenteum*, and confine myself, in this place, to the differences of the reproductive parts—

<i>GYNERIUM ARGENTEUM.</i>	<i>ARUNDO DONAX.</i>
<i>Dioecious</i> —spikelets dimorphous: dimorphism slight.	<i>Hermaphrodite</i> —spikelets all alike.
<i>Spikelets</i> —3- to 6-flowered, the uppermost florets more or less reduced, exceeding the glumes.	<i>Spikelets</i> —2- to 7-flowered, the uppermost florets more or less reduced, not exceeding the glumes.
<i>Rachilla-joints</i> and <i>callus</i> —long.	<i>Rachilla-joints</i> and <i>callus</i> —short.
<i>Glumes</i> —subequal, very narrow, linear, long, tapering, 1-nerved.	<i>Glumes</i> —equal, broadly lanceolate, shortly acuminate, 3- to 5-nerved.
<i>Valves</i> —lanceolate, produced into a very long and acuminate, 3-nerved, very scantily long-hairy, or glabrous in ♂, copiously hairy in ♀.	<i>Valves</i> —ovate to lanceolate-ovate, acuminate, finely and shortly blind, rarely entire, long-hairy near the base, with 3 excurrent primary, and usually with 2 to 4 short additional nerves near the base, the middle nerve often produced into a fine short awn.
<i>Pale</i> —equalling ½ to ¾ of the valve.	<i>Pale</i> —exceeding ½ of the valve.
<i>Lodicules</i> —ciliate.	<i>Lodicules</i> —glabrous.
<i>Stamens</i> or <i>staminodes</i> —3.	<i>Stamens</i> —3.
<i>Grain</i> —linear oblong; hilum linear, equalling about ½ of the grain, embryo equalling ½ to ¾ of the grain.	<i>Grain</i> —obovoid-oblong, broad, hilum basal, punctiform, embryo occupying almost wholly one side of the grain.

It will not be denied that the differences in the mode of growth, in the sexual conditions, and in the structure of the spikelets and the fruits, are quite equivalent to those differences on which the definitions of our generally recognised genera of grasses rest. The Cortaderas must therefore be considered as the representatives of a separate genus, for which I propose the name *Cortaderia*. *O. Stapf, Kew.*

(To be continued.)

VEGETABLES.

CAULIFLOWERS AND BROCCOLI.

ALTHOUGH there are numerous varieties of both Cauliflowers and Broccoli, and varieties which I should not care to be without, I am doubtful if we have more useful kinds than Early Erfurt, Walcheren, Autumn Giant, Self Protecting (Veitch), Snow's Superb Winter White, Penzance, Knight's Self Protecting, Ledsham Latest, Late Queen, and Methven's June. The above I have invariably found amongst the best I have as yet grown, and they serve to keep up a continuous supply. At the present time I am cutting firm heads of Autumn Giant, and Veitch's Self Protecting is beginning to turn-in, which it will do very rapidly. It is one of the best, for with care it is an easy matter to have this variety in good condition up to the end of the month of January, and occasionally still later; after which Snow's Winter White follows. It is a matter of importance to go over the beds of those varieties about to turn in, and dig up the plants when the heads are about the size of cricket-balls, and lay them in thickly together on a snug border, protecting the heads in severe weather.

t we have had no frost, and vegetation has not checked, and many of the young Broccoli for next year's supply have grown to a size than I like, but with smaller plants in store, all be safe in that direction.

nts growing under hand-lights and in frames d be kept abundantly aired—in fact, the lights d be kept off them night and day so long as it is

heads on those plants that are raised from seed sown in September and wintered in frames. The heads are fit for cutting at the end of May, and for this reason I should not like to discard this old method. Other matters which must not be overlooked are heavy manuring and deep culture, which always tell on light, shallow soils and dry seasons like those experienced of late years. The chief

n firm, moderately-enriched soil. I would not manure specially for this crop, but let it follow one that has been afforded a heavy dressing. If widely planted, this checks legginess, as does the comparative lack of manure in the soil; and if, in conjunction with these measures, the plants are heeled over to the north in the colder parts of the country, they will go through an ordinary winter without loss
H. Markham, Northdown, Margate.

SEQUOIA GIGANTEA.

This gigantic and elegant tree requires little comment, being now so well known and extensively grown in the British Isles; and so much admired by all lovers of arboriculture. A very fine specimen growing in the arboretum at Wrest Park, the beautiful Bedfordshire seat of Earl Cowper, has made rapid growth since the time it was planted. It was purchased from the late firm of E. P. Francis & Co., nurserymen, of Hertford, soon after the introduction of the plant into this country. It was then in a 3-inch flower-pot, and was afterwards shifted into one of a larger size. It was for a time used in house and conservatory-decoration. The late Mr. Snow, then gardener to the Earl de Grey, at Wrest Park, had it planted in the arboretum in the autumn of 1846.

Mr. Ford, late gardener at Wrest (who is shown as seated in the foreground of this magnificent and ornamental tree at fig. 110), at that time foreman-gardener under his uncle, the late Mr. Snow, at various times carried the plant from the gardens to the mansion, and *vice versa*; and assisted in planting it in the arboretum. This tree has now a height of 74 feet 3 inches, with a girth at the ground-level of 21 feet 3 inches; and at 3 feet from the ground, of 15 feet 3 inches. The branches extend from north to south 36 feet, and from east to west 35 feet. The soil is a sandy-loam, resting on a subsoil of strong clay, which to all appearances is very well suited to its requirements, as it is still making luxuriant growth, and remains feathered to the ground. *George Mackinlay, Wrest Park.*

COLONIAL NOTES.

ANTIGUA

"A BOTANIC station was established at Antigu in 1889, and a Superintendent of Agriculture was appointed to act as secretary of the Agricultural Society, and supervise the four botanic stations in the Leeward Islands. The superintendent was a highly-trained scientific man, who devoted himself with great earnestness to his duties, and who carefully investigated and suggested means for developing the agricultural resources of the islands. Numerous reports were prepared for general information, and 7500 pamphlets printed by government were distributed all over the Colony. These covered questions connected with the domains of botany, agriculture, geology, entomology, veterinary science, and allied branches. Investigations were also made into the diseases affecting Sugar-canes, and into the tick-disease in cattle. Experimental plots were started for the cultivation of new varieties of cane, and for testing the effects of manures in increasing the yield of Sugar. Numerous plants were propagated for distribution amongst all classes of the community, and detailed information furnished respecting their suitable cultivation. After a brief interval, the whole of this activity was suddenly stopped by the refusal of some of the members of the Legislative Council to pass the vote for the superintendent's salary, on the ground that the Colony could not afford it. The botanic station, in a crippled condition, has, it is true, been continued, but in an agricultural community requiring special scientific aid in these days of competition, and of disease affecting staple industries, the action taken by the Legislative Council was most unfortunate and inopportune, and it has tended to retard development in every branch of industry." *Report of West Indies Commission.*

FIG. 110.—SEQUOIA (WELLINGTONIA) GIGANTEA AT WREST PARK:
HEIGHT 74 FEET 3 INCHES.

a few degrees of frost at this season doing no to Walcheren. Early London, &c., two lies I have always found excellent for ring under glass. Many gardeners dispense the September sowing of Cauliflower seed, ring to raise plants of the Erfurt type under in February, and, with care and attention in ming-off previously to planting them out, good ts are obtained. But I have fewer buttoned

part of the kitchen garden at this place consists of light loam resting upon the chalk. The Broccoli and Cauliflower quarters will be heavily manured, and, if possible, trenched several spits deep, and by planting-time the land will have settled, and require no other attention than to pass the draw-hoes over it, and take out rather deep drills at a distance of 2 feet apart.

Broccoli succeed in an open position, and planted

ST. KITTS.

"A botanic station was started at St. Kitts, close to the town of Basseterre, in 1890. The site was the best that could be obtained for the purpose, and as a well laid-out ornamental garden, and a place of resort for the congested population of Basseterre, it has not been unsuccessful. It has been the means of raising and distributing many economic plants, such as 20,000 Arabian Coffee, 5000 Liberian Coffee, and 1000 Cacao plants, while latterly some valuable new varieties of Sugar-cane have also been distributed. The cost of maintaining this station is exceptionally small, in fact less than that of any other station in the West Indies. It is desirable that iron gates should be placed at the principal entrances, and that the station, for the present, at least, be entirely under the control of the Administrator, and not under a board. On land almost adjoining the station, an experimental station for Sugar-canes was started; but as already mentioned, owing to the removal of the superintendent of agriculture, nothing has yet been accomplished of a practical character." *Report of West Indies Commission.*

ROYAL BOTANIC GARDENS, CEYLON.

The newly-appointed Director, Mr. J. C. Willis, intends to publish every six or eight weeks a series of small circulars dealing with agricultural, horticultural, and botanical topics, with special reference to the work carried on in the Royal Botanic Gardens. One such circular deals with the Cacao canker, which is practically confined to one variety, the old red Cacao of Ceylon.

BOTANIC GARDENS, SAHARUNPORE AND MISSOURIE.

The Annual Report for the year ending March 31, 1897, has been published. Mr. Gollon does not report favourably on the Arabian Date Palm, and speaks more decidedly against the Sacaline (*Polygonum sacalinense*), which it appears is a failure as a forage plant in this garden. Eucalypts and Sisal Hemp do well. Cox's Orange Pippin and the Moor Park Apricot do well in the hills; and the American Dew-berry is well spoken of.

WEEDS.

The following is the preamble of a Bill to be presented to the Legislative Assembly of New South Wales:—"A Bill to provide for the eradication and destruction, and for preventing the growth of noxious weeds, and to prohibit and regulate the importation of noxious weeds, and of articles which might spread their growth." It is recommended that the Government "offer a reward for the discovery of a cheap and efficient means of eradicating noxious growths."

QUEENSLAND.

I send you two photographs, one representing a Tea-bush, a row of which is growing alongside of a quarter of Sugar-cane, a New Guinea variety called McLean; the other shows sprays of Coffee in berry, and Tea placed upon three sticks of the same cane. As the cane to the tip of the leaf is about 12 feet long, a portion is cut from the base, and the top is necessarily above the "back ground." The Tea grows very well, but there is no chance of its becoming a commercial success, as the expense of picking makes that next to an impossibility; but I have no doubt Coffee cultivation will become a large item in the Sugar-cane farmer's programme. My trees have borne a great crop of "Cherry" this season, and are not all gathered yet; but notwithstanding the crop, it has not been equal to the demand for seed, and before twelve months are past, there will be a good many hundreds of acres planted in this district. The manager of a company that has started a plantation about 23 miles from here came in one day; he told me he had not seen such a crop in Ceylon. There was an idea among the farmers that a great deal of scientific knowledge was required to succeed in Coffee-growing, but by writing, and by teaching those that have called for instruction, and to see for themselves, I think the fear has about died out. Cane-growing and cutting is laborious work compared to which Coffee cultivation is play. For several years a

pony (such as can be bought here for 7s. 6d.) and a light scarifier, can nearly do the keeping clean, very little hoe-work being required. The cane farmer has to work hard for from twelve to fifteen months before he can bring his cane to the mill or railway-siding, perhaps from 2 to 4 miles, and then he gets from 10s. to 14s. per ton for it; but the coffee-grower's ton of Coffee in the parchment will bring him an average of a hundred pounds. Thirteen years ago, when I first came to the colony, and occasionally saw an isolated Coffee-bush growing, very healthy, and bearing great crops, I was convinced that the Mackay district was well adapted for Coffee-growing. It was evident that both soil and climate were right. The one drawback is, that there must be some capital to keep a man going for three years, when half a crop is generally got; but when cane and Coffee-growing are started together, the cane returns money in from twelve to fifteen months, and enables the farmer to tide over the waiting time—but where capital is in hand, the Coffee grower may go 50 miles away from market, where he can get land for 2s. 6d. per acre, and five years to pay it in. Two to four days' journey with his team will bring his year's produce to market; and unless some unforeseen calamity overtakes the industry, Mackay is likely to become in a few years a large Coffee exporting place. *D. Buchanan, State Nursery, Mackay.*

OLEARIA FORSTERI.

The shrub or small tree of which we give an illustration (fig. 111, p. 381), is a native of the northern and middle islands of New Zealand. When seen out of flower it has much resemblance to some *Elaeagnus*, with its coriaceous, undulate, reticulate leaves, thickly covered with pinkish or cream-coloured down on the under surface. The slender cylindric heads are fascicled, and, what is singular, they mostly contain but a single floret (rarely two), so that the term composite is not strictly applicable. They have a delicious perfume, so that the plant may be commended to the notice of connoisseurs, especially to those resident in the southern and western counties—especially near the sea. Our specimen was grown in the garden of G. V. Hart, Esq., Q.C., Woodside, Howth, Dublin, and was kindly forwarded to us by Mr. Burbidge. We have no personal experience to offer, but the evidence before us justifies us in recommending this plant as likely to be valuable by the seaside. The plant is figured and fully described in Mr. Kirk's excellent *Forest Flora of New Zealand* (1889), t. 137. In New Zealand it is much infested with a dipterous insect which forms leafy galls in the buds, with the result that the flower panicles are enlarged whilst the foliage is reduced in size.

* *Olearia Forsteri*, J. D. Hooker. *Handbook of the New Zealand Flora* (1867), p. 127.

EDEN HALL.

THE Cumberland residence of Sir Richard Musgrave, Bart., is pleasantly situated in the valley of the Eden, some $3\frac{1}{2}$ miles from the picturesque little market town of Penrith on the L. & North-Western Railway, and 1 mile only Langwathby on the Midland route. Sheltered amid the Cumberland Hills, the Musgraves have, believe, found a home since the time of William the Conqueror, during which long period the place has passed in direct male succession.

The hall itself occupies a position immed inside a park of about 300 acres extent, and commands a magnificent view of both mountain woodland scenery. Approaching the hall from Penrith side we pass through the lodge-gates, and proceed along a broad, winding avenue substantially flanked on each side with stately timber, Oaks and Chestnuts being conspicuous for their size, narrow walk on the right brings into our view fine Larch-trees. Beech and Limes are also represented, but the most remarkable object is two giant Cedars of Lebanon (fig. 112 on supplementary sheet) growing side by side, near to what is called the French garden (fig. 113 on supplementary sheet) geometrical arrangement of flower-beds, immediately under the west front of the hall. We are unable to record the age of these twin-trees, but judging by noble dimensions and aged appearance, they have braved the storms of more than a century, who knows they did not spring up in the days of the good fairies, coming to drink to "The Lady of Eden Hall," lost their cup in the little well mysteriously hidden in the clumps of Boxwood observed on the left of the flower-garden under the terrace, and which is now preserved with religious care; for—

"If this cup should break or fall,
There goes the luck of Eden Hall."

Flower-gardening is carried out extensively and in a style completely in harmony with the surroundings. The French garden already alluded to laid out on gravel, the beds being edged with a work, and at the time of our visit, furnished with a rich assortment of suitable subjects, noticed amongst them being a pretty variety of *Begonia*, named *Fairy Queen*, a compact-growing variety with bronzy-coloured foliage, and carmine-red flowers similar in form to the type. Tuberous-rooted varieties of *Begonia* were also well represented, and were especially pleased to see our old favourite *ceolaria* (*amplexicaulis*) holding its own, and sending a striking contrast to a splendid *Heliotrope* growing alongside.

What pleased us most here, however, was the manner in which Mr. Smith, the gardener, had fitted out the centre and other beds conspicuous in the design; some idea of the effect may be realised when we say they were occupied by splendid examples of noble plants as *Lavatera arborea* variegata, *japonica* variegata, *Hyacinthus* (*Galtiana*) candida, a noble subject for massing, *Eucalyptus globosa*, *Lobelia* Queen Victoria, *Carnation* Ruby, *Scarlet Pentstemons*, *Veronica Andersoni*, *Spectabile*, *Dactylis elegantissima*, &c., all arranged with a view to preventing a flat and uninteresting appearance, and to form a connecting link, so to speak, with the general surroundings. Along the top of the terrace, in front of the hall, a series of oblong beds, similarly filled, occupy positions at regular distances on the grass, and a spacious border immediately under the terrace wall, clothed with Ivy, was a magnificent arrangement of tall Sunflowers, Dahlias, Tobaccos (*Nicotiana*), *Pentstemons*, *Chilian Beet*, *Calceolarias*, *Violas*, &c. *S* beds of large size below the hall, until recently, filled with evergreens, and, considering their dimensions, it was a great undertaking, with the facility at command, to furnish them with such plants as those already named, supplemented with clumps of *Coreopsis*, *Marigolds*, *Scarlet Gladioli*, and the like.

THE PLANT-HOUSES.

Leaving the flower gardens, and passing under a row of veteran Limes which effectually hides the

FIG. 112.—CEDARS AT EDEN HALL, CUMBERLAND. (SEE P. 380.)

FIG. 113.—FLOWER-GARDEN AT EDEN HALL, CUMBERLAND. (SEE P. 380.)

view a walled-in garden of something like $1\frac{1}{2}$ acre, in which is situated the bulk of the glass, we enter a range of plant-houses replete with a miscellaneous collection of plants, consisting largely of decorative subjects, both flowering and foliage. This department really consists of three separate ranges, the larger being filled with specimen plants, a considerable number of which are always required for the embellishment of the dwelling-rooms. Small plants are practically useless for this purpose here, and consequently specimen Palms of large size are numerous, Kentias predominating. Bamboos are also tensively used, and of these there were some noble

superba that literally festooned the roof of one of the stoves. Never have we seen this magnificent "trailer" in better condition than here. Orchids are not extensively grown, but *Calanthes*, because of their winter value, form an exception. We must not fail to mention the collection of about 1000 *Chrysanthemums*, and the winter-flowering *Begonias*. Violets are specially well done here; those we saw, indeed, were perfect examples of good health, and full of promise for a generous harvest of bloom. *Marie Louise* and *Neapolitan* are the varieties chiefly grown at present. Zonal *Pelargoniums* in the semi-double class are prepared in large numbers for winter

the time we saw them, were exceedingly fine, both in respect of size of bunch and berry, as well as finish. A start has been made to renew the Vines, and a young lot of canes planted twelve months ago looked very promising. A houseful of young Figs about the same age were also looking well; and Bananas were exceptionally promising—one plant in particular carried a wonderful cluster of fine fruit.

Melons are given a special share of attention. The varieties *Model*, *Best of All*, and a cross of Mr. Smith's own raising named *Sir Richard*, are the favourites. The latter, a green-flesh variety, combines with exquisite quality a beautifully netted

FIG. 111.—OLEARIA FORSTERI: HARDY SHRUB. (SEE P. 380.)

specimens of *aurea*, *violacea*, and *gracilis* coloured *Dracaenas* also find favour for the same purpose, as do *Acalyphas*. *Caladiums* are an imported feature during the summer season. *Crotons* are represented by clean, well-coloured plants of such varieties as *Queen Victoria*, *Prince of Wales*, *Weismanni*, *Aigburthensis*, &c.

Amongst flowering subjects, good plants of *Anthurium Andreanum* were conspicuous objects with their handsome spathes; *Eucharis grandiflora*, and *Pancratiums* of sorts are grown in large numbers, and in healthy condition. *Allamandas Hendersoni* and *Williamii* were also full of bloom; and ere we forget, we must pay a tribute to the glorious *Gloriosa*

flower, and a small house full of *Gardenias* bristling with short-jointed, sturdy shoots gave promise of a fine quantity of bloom. Forcing plants, such as *Lily of the Valley*, *Lilacs*, *Spiraeas*, bulbs of sorts, &c., are also extensively used, and a batch of the maximus variety of *Helleborus* showed that its value is also known.

THE FRUIT-HOUSES.

Making for the fruit department, we passed into a lean-to range of considerable dimensions, three of which houses are devoted to Grapes. The *Hamburghs* were all but finished, though there was sufficient evidence of a heavy crop left, and very creditable they were. *Muscat of Alexandria*, hardly ripe at

appearance, and what is of still more importance, a constitution so vigorous that as many as a dozen fruits of good size may be obtained from one plant, each ripening off in its turn, a very unusual characteristic in a Melon so far as our experience goes. Something like 2000 *Strawberries* are grown in pots. Considerable alterations are contemplated in the hardy fruit department, more especially amongst the wall-trees. Some young *cordon Pears* planted a year ago indeed have already made a good start.

With a large establishment to cater for, vegetable culture necessitates a great deal of attention; and the area devoted to these, with fruit-trees interspersed, amounts to about 3 acres. Though space compels us to

be brief in our remarks on this department, we should be remiss did we omit to acknowledge the thoroughly practical methods adopted to secure a good supply; ample evidence we recognised in the total absence of vacant ground, large breadths being devoted to winter Brassicas of various sorts in successional stages. It may be worthy of remark that *Stachys tuberosa* is much esteemed as a winter vegetable here, and is consequently grown in considerable quantity. *A Correspondent.*

THE ROSARY.

ROSES, WHAT TO PLANT, AND HOW TO PLANT THEM.

(Concluded from p. 361.)

I PUT at the head of this article, how to plant them, but I hardly know how to go on with this subject. I have before me the little brochure issued by the National Rose Society, "Hints on Planting Roses," where the whole subject is entered upon with such minuteness of detail, that I think the veriest tyro could not well make a mistake about them. There are two points on which beginners may make a mistake, viz., the depth at which they are to be planted—I allude to dwarf Roses. I would not recommend any beginner to try standards. Care should be taken that the point of junction should be buried about an inch beneath the soil, so as to give the Rose a double chance. Another point is, firm planting. When the Rose-plant is placed in the hole prepared for it, some soil should be put in, and then firmly trodden down, of course taking care that the roots are not injured. These are the two main points to be attended to in the planting of Roses; but again I would say to every one who wants information on the subject, consult the little book above alluded to. To those who have space for it, the grouping of Roses, that is, the putting a large number of one kind into a separate bed, has a most pleasing effect; but then, of course, space is required for this, and those for whom these remarks are intended are not likely to have much at their disposal. They cannot do much for effect, but I think it is well to vary the colours as much as possible in the beds—not to have all reds in one place and all whites in another, but to disperse the colours up and down the beds. The present autumn is one of the most remarkable I can recollect since I began to grow Roses. Generally at planting time our beds are saturated with moisture; but in this part of the country (East Kent) the ground is so dry one has to water, and it is so hard that I am told the shrubs and fruit trees can only be got out of the ground by using a pickaxe. How it will fare with our poor Roses I know not. We have had a splendid time for ripening the wood; but if, as some imagine, this spell of dry weather and high temperature by night and day is to be followed by severe cold, it is likely that they will suffer much. But we must hope on, and do all we can, if the severe weather comes, by mulching and protection to save our pets from injury. *Wild Rose.*

BOOK NOTICE.

HARDY PERENNIALS AND OLD-FASHIONED GARDEN FLOWERS. By John Wood (Upcott Gill, pp. 330).

THE object of this book is to furnish the names and descriptions of really useful and reliable hardy and perennial plants, together with cultural hints on each plant, for, says the author, "to be able to grow a plant well is of the highest importance, and the first step towards a full enjoyment of it." We endorse the first proposition entirely; and though we think the facts might have been differently expressed, we shall not quarrel with the author's intention in the second. Perhaps the author is too exclusive in his taste when he condemns the bulk of the Michaelmas Daisies, and has not a good word for *A. acris* or "Robert Parker." Surely Mr. Wood cannot have

availed himself of the report of the trials of these plants conducted at Chiswick. So with *Campanulas*, only five or six are named, whilst *C. isophylla*, *C. carpatica*, *C. turbinata*, and many others are not mentioned. Only one *Chionodoxa* is alluded to. Mr. Wood, like many others, is successful with the lovely *Gentiana scabra*; but we know of gardens where, in every possible variety of soil and aspect, the plant cannot be induced to produce its flowers. Mr. Wood's cultural notes are very serviceable, and his book is sure to be useful to amateurs. Missprints, such as *Orygalis* for *Orgyalis* suggest that in a future edition the proofs should be read by a competent botanist.

FLORISTS' FLOWERS.

"MRS. R. JONES" CHRYSANTHEMUM.

LAST spring I bought in some new Chrysanthemums, and one of them was Mrs. R. Jones. A plant of this variety at the present time, although growing in an 8-inch pot, has three splendid blooms, the largest being fully 9 inches in diameter, and 5½ inches deep. I prefer the variety to any other white that I have grown, and am rather surprised not to have seen it more frequently among winning stands at shows this year. I have also plants of Western King which have very good blooms, but it is rather too compact to please everyone. In Mrs. R. Jones the medium between great looseness and compactness is found. *A. J. Long, Wyfold Gardens.*

THE WEEK'S WORK.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Drogheda, Maidenhead.

Herbaceous Borders.—During the continuance of mild dry weather, the re-arrangement of the occupants of these borders, as may be called for by the clumps having become much too large or outgrown their allotted space, may be carried out. The better method is to lift all of the plants in the border, laying them meanwhile temporarily, and trench and manure it. After allowing the soil time to settle, make it firm by tramping it evenly and regularly; and then in dry weather proceed to arrange and set out the various plants or convenient sized pieces of the same, preferably the outer portions of such clumps. New borders may be made and planted at this season if put in hand forthwith, whereas if left until the spring the ordinary routine work will often prevent the performance of the work. If the work be carried out at the present season, and the border at the finish be mulched with leaf-mould or Mushroom-bedding, the plants will make some degree of progress underground, starting strongly in the spring; whereas spring-planting always involves late starting into growth, and to a certain extent late flowering. Moreover, the spring is too late for bulb planting or bulb removal.

Rose Borders.—The treatment of impoverished borders was dealt with in a former Calendar, but where it is not necessary to take radical measures, a heavy dressing of half-rotted manure will suffice, this dressing acting also as a protection against frosts, if allowed to lay on the surface till the spring, when it may be pricked in, or covered with fresh soil. Although the pruning of Roses should be performed in March and April, strong growths should be shortened back at this season so as to avoid having them broken off by wind or snow, causing the loosening of the plants in the soil.

Lobelia cardinalis.—These plants may be left to winter in the beds if they are afforded a light covering of bracken or litter in frosty weather. This is the simplest means of wintering them; but if an increase of the stock of plants is desired, it is better to lift the entire stock and store them in a greenhouse-pit, dividing and potting them in early spring. The same holds good if, owing to the position of the bed, they cannot be afforded protection where they grow.

Window-boxes, &c.—Owing to the mild weather, and the protection afforded by the window, the summer occupants of the boxes have continued in a fairly bright condition up to date of writing; but it is quite time, notwithstanding this, to replace them with the winter shrubs, bulbs, &c. The shrubs may consist of the varieties enumerated for filling winter bedding, the other plants being Wallflowers, *Myosotis* in variety, variegated and green *Vincas* &c.

Bulbous Irises.—The planting of these beautiful species should not be longer delayed, the bulbs deteriorating if kept out of the ground after this date. These varieties of the Spanish and English Irises, whose usual season of flowering is June and July, should always be grown if a succession of Iris is desired; their handsome colours and quaint shapes vieing with those of Orchids. These species like a rather light and friable soil, and a warm sunny position; and if the soil be impoverished, a good dressing of rotted stable-dung, or failing that, one of leaf-mould, should be afforded, and the ground dug 1 foot deep. If the bulbs are most likely to be the case, are planted in little colonies in a border of herbaceous perennials, these directions should still be carried out. Let the ground be consolidated by tramping it, and proceed to plant the bulbs, which may be put 4 inches deep, and 1 or 2 inches apart if planted in patches of a dozen or more bulbs. The Spanish Iris (*I. xiphium*) naturally starts rather the earlier into growth, and flowers a week or two before the so-called English Iris (*I. xiphoides*), and for furnishing out flowers the former is, perhaps, the more desirable. The prevailing tints are blue, purple, and violet, but there are pure white and yellow varieties; the variety Gold Cup being a very distinct one, with rich bronzy-purple tints; Lady Blanche and La Vestale are pure white; Jupiter and Canary Bird are of shades of yellow, and Celestial has light blue flowers. The bulbs may be bought in mixture of colours at a reasonable price. The English Irises partake somewhat of the character of the others, but they are of slightly dwarfier growth, as well as a little later in blooming, and can therefore be grown so as to make a succession to the Spanish varieties. The same methods of culture apply to each. The flowers possess great variety of colour, and contain pure white, lilac, blue, and purple tints as selfs, or variously mottled. Collections of bulbs in distinct colours may be purchased for a few shillings, and mixed colours are even cheaper. In the event of frost making it inconvenient to plant in the open, these bulbs may be potted to the number of five in a 6-inch pot, and stood in cold frames, or plunged out-of-doors in cocoanut-fibre refuse, or coal-ashes, till the spring, at which season the bulbs may be transferred without disturbance to the borders.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorset.

Pleiones.—Few of the smaller-growing Orchids are more beautiful than the Pleiones, familiarly known as Indian Crocuses, and more correctly as *Calanthes*. They are not only valuable decorative plants, but they are very useful for furnishing out flowers; and if amateur Orchid-cultivators knew better the ease with which the plants may be grown, doubtless many more gentlemen would grow them. The following varieties are worth places in any collection:—*Pleione lagendaria*, *P. concolor*, *P. Wallichiana* or *præcox*, *P. maculata*, and its variety *alba*. The plants are now passing out of bloom, and it may be noticed that the part enclosing the flower-stem is the growth which will be formed into plump bulbs, and this time next year carry flowers. When the flowers fade, these young green shoots commence to push out from their base a number of small white roots, and no time should be lost before re-potting the plants. Turn them out of their pots or pans, removing most of the old soil, and cut off all dead roots, pulling out the old decayed bulbs. Instead of dividing the pseudo-bulbs, and bedding them out, as is often practised, repot them in clumps just as they are. At no time during the past eight years have Pleiones been divided here at Burford, and at each flowering season, when the varieties are grouped together, they have always been a picture of loveliness. My method is to grow them in 6-inch pots, with the bulbs almost touching each other; and when repotting I take away those bulbs which may have grown beyond the main clump, and make up another potful in the same way as the older examples. It is immaterial whether pots or shallow pans are used, excepting that pans are best where stage-room is limited, as they may be suspended from the roof. Whichever be used, ample drainage must be given to carry off the large supplies of water these plants require when in full growth. Over the crocks it is necessary to place a layer of sphagnum-moss, or a thin turf of loam, with the grass-side downward, so that the compost may be kept moist, and the drainage unobstructed by soil. Then fill nearly up to the rim of the pot with the following compost: equal parts of fibrous

loam, peat, and sphagnum-moss, with a moderate quantity of coarse silver-sand. Upon this soil the base of the clump should rest, filling up firmly around the bulbs with the compost. Should there be any bare spaces between the bulbs, it should be filled in with the roughest of the potting material, giving preference to the sphagnum-moss as being retentive of moisture. When repotting is finished, place the plant near the roof-glass in an intermediate-house, but give scarcely any water until the plants start to grow vigorously. As the roots and foliage develop, so must the quantity of water afforded be increased, and when thoroughly established, the plants require almost unlimited supplies; and in addition to the ordinary watering, an application of weak liquid-manure water about once a week is very beneficial to them. In the spring and summer months, the plants will be greatly benefited, and red-spider may be checked, by syringing overhead and underneath the foliage two or three times a day. *Pleione Hookeriana* and *P. humilis* coming from a high alpine region, at elevations ranging from 7000 to 10,000 feet, should at all times be grown in the cool-house with the *Odontoglossums*. Both species have now completed their growth, and may be suspended close to the glass. During their period of rest, water them often enough to prevent the bulbs from shrivelling. The flowering season is January and February. *P. humilis* has sepals and petals of a delicate lilac colour, the lip is margined with white, and exquisitely fringed with long white hairs. *Pleione* flowers are easily gathered by giving them a gentle pull, when the stem will readily part from the base of the growth. When in bloom, the plants should be placed in a dry atmosphere, and the flowers will remain fresh for a considerable time.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, late of Eastnor Castle, Leicestershire.

The Pine-stove.—In the fruiting-house some of the older Smooth Cayenne Pines will now be getting ripe, and in order that they may ripen satisfactorily, and be of good flavour, water must be very sparingly applied to them, and not any excepting the soil is very dry. Let the air be kept rather drier, with a steady warmth of 70° at night, and 80° by day, with sunshine. Afford the plants very little air, then only on fine days for an hour or so about noon. Other fruits that may be swelling may have a little guano or other fertiliser sprinkled on the soil before affording water, or it may be dissolved in the water used. Be careful in affording water to any of the plants at this season, when there is but little loss of moisture from the soil. Let the walls, &c. be moistened with weak liquid-manure occasionally, and with clean water once or twice daily; and secure the fruits with broad strips of matting in order to have erect crowns.

Successions and Suckers should now be resting, and beyond an occasional examination to see that they do not become very dry at the root, they will not require much attention. Let the night temperature be kept at about 60°; 5° lower will not harm them, should very cold weather set in. If the garden is near a smoky town, the glass should be washed occasionally. Frigid-domo or canvas blinds are very useful in economising fire-heat, but they must not be let down till nightfall, and should be rolled up by daylight, or half their usefulness will be counteracted and lost.

Pot Vines.—Where these were started at a very early date, the buds will be commencing to break, and if they are doing this in a regular manner, the canes may be shifted from the horizontal position, and slung up to the rafters for a few days, about 2 feet from the glass, and then secured to the trellis in the proper manner. By proceeding thus, the risk of checking growth is much reduced. Canes that break irregularly may have the terminal buds rubbed off, so as to divert the sap into the backward buds. As the Vines grow, more water at the root will be required; but root-action being sluggish as yet, care must be taken that the Vines do not suffer from excess of moisture, neither must they lack moisture. Maintain the hot-bed at a steady degree of warmth, affording fresh warm material as often as required. The syringing of the rods may be suspended for a time when they commence to break, as the points of the shoots are liable to damp at this time of year, which means, of course, that the bunch therein will be spoiled. A moist, genial atmosphere may be kept instead by damping down twice or thrice daily. Whenever the Vines have to be afforded water, it should be in sufficient quantities to moisten the entire mass of soil, and have a warmth of 85°. The

night temperature may now be raised to 60°, and by day to 70°, the temperature and the degree of moisture being governed to a great extent by outside conditions, a rule which, if more generally adhered to, would tend to reduce the red-spider pest so common on early-forced plants.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton Hoe Park, Luton.

Richardias.—There should now be plenty of spathes on such of these as were kept in pots all the summer, and the pots being filled with roots, it will be safe to afford them weak farmyard manure-water once in three or four days. The *Richardias* that were planted out in the open with the idea of furnishing spathes late in the winter, will have begun to fill the pots with roots, and establish themselves, and they should be placed in a greenhouse, and fumigated at regular intervals for the destruction of greenfly, with which they are nearly always liable to be infested. When spathes in quantity are wanted at the Christmas season, the more forward of these should be placed in a house having a slightly higher degree of warmth, say 50° to 55° by night, and 60° by day.

Hydrangea hortensis.—The plants should now have the protection of a cold frame, and the pots be plunged to the rims in fine coal-ashes or new tree-leaves, leaving space for the air to circulate freely among them.

Fuchsias.—Those plants which have been employed in the conservatory, and have passed out of flower, should be stood close together in a frost-proof glasshouse or well-lighted shed for the winter, water being withheld all the while.

Chrysanthemums.—The season is almost here when the propagation of the plants must begin; and while there is yet a little time, an effort should be made to ascertain if every plant is correctly named. Those which are pushing up many shoots should have the latter thinned somewhat, in order to strengthen the plant, and the shoots which are to serve as cuttings. Any varieties that appear unlikely to develop shoots should be cut down to within 1 foot of the soil forthwith, the surface slightly stirred, the exposed roots covered with soil, and the plants stood near to the glass in a greenhouse, and afforded water only when the soil has become dryish.

Violets.—Thus far the season has been favourable to *Violets* in frames, and flowers are now abundant. Such of the beds as were top dressed with Cocoa-nut-fibre refuse may not be found to require water, but unmulched beds may be found to require it. This should be applied without the rose on the can, so as to avoid wetting the leaves. Continue to ventilate the frames freely, pushing the lights back for an hour or two each day, or until it is seen that the underside of the glass is quite dry. Remove decaying leaves as soon as remarked, and place protecting material in readiness to cover the mats if sharp frost is impending.

THE KITCHEN GARDEN.

By W. H. POPE, Gardener, Highclere Castle, Newbury.

Manuring Land and the Rotation of Crops.—Advantage should be taken of dry weather to wheel manure on to the kitchen-garden quarters and borders; but, before doing this, it is necessary to prepare a plan of the cropping for, at the least, one year in advance. For instance, plants of the *Brassica* tribe should not be grown on the same soil for two years running. Peas and Beans should also have change of ground; and by arranging the different crops to follow each other, better results may be looked for, not only by husbanding the resources of the soil, but by more economy in working it, than by following the opposite method. After a root crop, the ground should be well manured, and dug deeply at an early part of the year, the surface being left as roughly as possible, or thrown up into ridges. The exposure of so much of the soil in this manner will cause the destruction of numerous larvae and chrysalides of insects, &c., injurious to crops. The early Celery-crop may be followed by the main-crop of Onions, the ground being ridged or roughly dug as fast as it is cleared; the mid-season and later Celery-ground being reserved for Beetroots, Parsnips, Carrots, &c., no other manure being added beyond a dressing of soot in the spring. Late varieties of Potatoes may be succeeded by Kale, and Coleworts for spring-cutting, the plants, of course, being prepared in a measure by having been lifted from the seed-beds, and pricked out thinly to keep them sturdy. Of course, there are different subjects, as summer Spinach, Lettuces,

Radishes, and many others for which it will not be necessary to manure the land in an especial manner. Spinach for instance may be sown between rows of Peas, or as an edging close to the paths; it is an evanescent crop, never occupying the ground in the summer for more than six or seven weeks.

Early Broccoli.—If the rows of Peas are placed 20 to 30 feet apart, early Broccoli may be planted in the spaces between the rows, the removal of the Peas letting more air and light into the quarters. If Peas are given 6 feet between the rows, two rows of plants may be put in each space, and if the ground be trodden hard so much the better for the Broccoli. The ground occupied by late Broccoli not falling vacant till the end of May, should be reserved for the Scarlet and other Runner Beans and for Celery, the rows of the former being 10 to 12 feet apart; and between them the mid-season and late Celery may be planted, the rows running north and south; or Turnips, Dwarf Beans, &c., may be grown there. Wide and deep trenches should be provided for the Beans, and plenty of rotten manure mixed in the staple, with some fine soil put on the top, before sowing the seed. Lettuce is best provided for during the summer months by planting or sowing a batch at short intervals on the Celery-ridges, as also early Endive, Radishes, or other quick-growing subjects.

Vegetable Refuse, &c.—In all gardens there is a heap of decaying vegetable refuse and other rubbish, the accumulations of the summer months. This ought now to be turned, the decayed portion thrown into a heap by itself, the rougher materials being burnt, and the resulting ashes added to the heap, then add a sixth part of quick-lime, and well mix all together. Thus treated, it forms a valuable fertiliser, and will be found useful for many purposes during the spring and early summer.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Manuring Strawberry Plantations.—Advantage should be taken whenever the ground is hard and dry to wheel manure on to the Strawberry-beds, and to spread it between the rows and close up to the plants. The manurial ingredients in this dressing, which may be about 2 inches thick, are carried down to the roots of the plants by snow and rain, benefiting them without the attendant loss of roots that follows the common practice of forking the manure into the spaces between the rows. Weeds that may have sprung up in the beds should be pulled up before applying the dressing.

Pruning Currant-bushes.—The established bushes of Red and White Currants may now be pruned, cutting most of the lateral shoots within an inch of the old wood, but leaving the leading and secondary leading shoots of branches about 6 to 9 inches in length, according to position. This conveys the general idea of the pruning of these bushes, but the pruner must also have in his mind's eye the symmetry of each, leaving shoots of varying length, or removing some entirely, where it may seem to be called for. All crowding of the shoots or main branches should be avoided or remedied. Old bushes in a crowded condition may be turned into profitable ones by thinning out the older and worst-placed branches, and shortening in the fruit-spurs if these are of great length. If the branches are lichen-covered, scrape them with a hard-wood scraper, and strew quick-lime over the others whilst damp. This dressing is useful in other ways, injurious insects and the larvae often concealed in the lichen being likewise destroyed by it. Black Currants require that some of the older branches be removed annually, and an equal number of shoots of the current year, of uniform strength, left to take their places; weak wood, unless needed to increase the size of the bushes, being removed. This done, and the prunings removed to the fire-heap, a good dressing of short manure should be forked into the ground, between and around the bushes. Gooseberries are pruned in the manner advised for black Currants, leaving the centre of the bushes well opened out. Where bullfinches are troublesome, the pruning of the Gooseberry bushes should be delayed until growth begins, by which time the birds will have done their worst, and the pruner will then have buds on the shoots from which to select. When pruning bushes of any sort, any of the shoots which are likely, when in leaf and fruit, to droop too near to the ground, should be shortened or removed.

Wall-Trees.—The pruning and training of wall-trees should be pushed on with during open weather—in accordance with the advice that I gave on subject on November 6, p. 325.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR DECEMBER.

SATURDAY,	DEC. 4	{ Society Française d'Horticulture, London Isle of Wight Horticultural Society, Meeting.
TUESDAY,	DEC. 7	{ National Chrysanthemum Society's Winter show in the Royal Aquarium, Westminster (3 days).
TUESDAY,	DEC. 14	{ Royal Horticultural Society's Committees.
SATURDAY,	DEC. 25	—Christmas Day.

SALES FOR THE ENSUING WEEK.

MONDAY,	Nov. 29	{ Dutch Bulbs, at Protheroe & Morris' Rooms. Dutch Bulbs, at Protheroe & Morris' Rooms. Japanese Lilies, Palm seeds, &c., at Protheroe & Morris' Rooms. Fruit Trees, Evergreens, and Conifers, at Lee's Nursery, High Road, Ealing Dean, by order of Messrs. Chas. Lee & Son, by Protheroe & Morris (two days). Bulbs and Plants, at Mr. Stevens' Rooms.
TUESDAY,	Nov. 30	
WEDNESDAY,	DEC. 1	{ Dutch Bulbs, at Protheroe & Morris' Rooms. Roses, Fruit Trees, Border Plants, and Bulbs, at Mr. Stevens' Rooms.
THURSDAY,	DEC. 2	{ Dutch Bulbs at Protheroe & Morris' Rooms. Bulbs, Plants, Shrubs, Palms, &c., at Mr. Stevens' Rooms.
FRIDAY,	DEC. 3	{ Dutch Bulbs, at Protheroe & Morris' Rooms. Imported and Established Orchids at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—41.3°.

ACTUAL TEMPERATURES:—

LONDON.—November 24 (6 P.M.): Max., 47°; Min., 37°.

PROVINCES.—November 24 (6 P.M.): Max., 52°, south-west Ireland; Min., 39°, north-east Scotland.

Weather dull, foggy, and mild.

A PAPER at the Royal Horticultural Society from Mr. JOHN WRIGHT of the *Journal of Horticulture*, who is not only an experienced judge, but a member of the press, which is the great Court of Appeal, is of great interest to those concerned in the preparation of schedules. No doubt Mr. WRIGHT's experience is like our own. We find that most of the difficulties and disputes which arise, and which are referred to us, depend either upon faulty drafting of the schedule, or upon a misapprehension of its meaning. Incompetence on the part of a judge scarcely ever occurs, though, of course, equally competent judges may some-

times come to different conclusions. Wilful misjudging has never come under our notice. In continental shows a bias has, in our experience, sometimes been observable; but then it has been a bias of an amiable character, and one that has not inflicted injury on anyone.

The rules of judging formulated by the Royal Horticultural Society furnish valuable assistance to the framers of schedules, and it is to be wished that those rules were made the universal standard, as they can be revised each year, and modified if change be considered necessary.

The point system is excellent in all doubtful cases, but as to the value to be given to 1st, 2nd, or 3rd prizes, as the case may be, that is a question that the judges have nothing to do with. The maintenance of a regular proportion between the classes may be desirable in most cases, but it is possible there may sometimes be local reasons which induce a committee to act otherwise.

Competition for the mere sake of getting money-prizes is despicable, little if any better than gambling, and leads to such deplorable results that many employers forbid their gardeners to exhibit. The higher the aim, the less personal the object, the better is the show, and the better the ultimate results to all parties concerned. It may be difficult to realise this at the time, but experience shows it to be true in the long run. It would be interesting to trace the causes that led to the abandonment of some societies. For our own part, we feel convinced that one cause of the want of success of such societies is to be found in the fact that the supporters thought more of personal interests and of prize-giving and prize-winning than of the progress of gardening. At any rate, it is incontestable that the most successful societies are those which place the interests of gardening foremost, and the benefit of its members or of exhibitors in a subordinate position.

Commencing with an unqualified testimony to the good effect of horticultural exhibitions, Mr. WRIGHT referred to the features of successful and unsuccessful societies, afterwards giving hints upon the management of a society. Reference was made to the composition of committees, the importance of establishing a reserve fund, the formation and compilation of schedules, the amateur question, the duties of exhibitors, of secretary, committee, judges, &c., and many other incidents in connection with the exhibition of horticultural produce.

One of Mr. WRIGHT's principal references was that to a system of judging exhibits known as "the point value" method, and which has been practised at the Carshalton Society's Show for some years. Briefly, under this system a sum of money would be apportioned to each class, and it would be awarded to 1st, 2nd, or 3rd prize exhibitors, according to the number of points awarded each collection by the judges. The amount of disparity between each prize in a class would be exactly proportionate to the difference between the value of the several exhibits. Occasionally, therefore, there would be little difference even between the 3rd prize and the 1st prize.

LINNEAN SOCIETY.—An evening meeting will be held on Thursday, December 2, 1897, at 8 P.M., when the following papers will be read, viz., 1, "On the Anatomy of *Caudina coriacea*," by Professor ARTHUR DENDY, D.Sc., F.L.S., &c.; 2, "On some Desmids from the United States," by Messrs. W. WEST, F.L.S., and G. S. WEST. Exhibitions:—1, Specimens of Galls of *Cecidomya*, by Professor J. B. FARMER, F.L.S., &c.; 2, An Egg of *Eobidna*, by Mr. MARTIN WOODWARD.

RAMIE FIBRE.—Messrs. MACDONALD, BOYLE & Co., of 39, Victoria Street, S.W., write in reference to a note on "Ramie Fibre," that appeared in these pages recently, that we must have been misinformed. The Midlands Spinning Co., of Long Eaton, have been working Ramie under their process for the past four years, and tons of the yarn have been turned into lace and other materials.

CHRYSANTHEMUM PENNSYLVANIA.—A bloom of this variety of incurved Japanese Chrysanthemum has been shown us by Messrs. F. SANDER & Co., who obtained it from the raiser, HUGH GRAHAM, Esq., U.S.A. It is bright yellow in colour, has ribbed, rather broad florets that incurve, and are slightly turned to one side. The bloom is 4½ inches deep, and 5½ inches in width, and has a full and rather dense centre. The flowers appeared rather rough, but having been cut so long, it would be difficult to estimate it correctly.

BEGONIA GLOIRE DE LORRAINE.—The numerous occasions on which this beautiful fibrous-rooted Begonia has been exhibited recently, have proved it to be one of the most valuable of autumn-flowering plants. It responds to good cultivation by producing pretty, well-shaped plants, that are literally covered with abundant rosy-pink flowers. The collection of plants, shown from a private establishment, and referred to in our report on p. 386, of the Royal Horticultural Society's Show on Tuesday last, was a most noteworthy one.

HONINGTON CHURCHYARD.—On Monday, October 18, the Bishop of Coventry consecrated a handsome lych-gate and a new burial-ground at Honington Church, the gift of F. TOWNSEND, Esq., of Honington Hall. The ceremony was rendered the more touching by the fact that a funeral was about to take place on the new burial-ground of the only son, aged five years, of Mr. GUY, the head-gardener at Honington Hall.

HEAVY BUNCHES OF GROS GUILLAUME GRAPE.—Under the more common but erroneous name of Black Baroessa, Mr. NELSON, gardener to Mr. BARNES, a gentleman residing at Chesterfield, exhibited three bunches of this fine-looking Grape at the recent Birmingham Chrysanthemum show, the heaviest of which weighed 9 lb., and the others nearly as much. The bunches and berries were perfect in every point. It is a variety of a very uncertain character, cropping well in some places, and scarcely at all in others; and when a few bunches only happen to grow on a vigorous, large Vine, they usually come of prodigious dimensions. Mr. BARROW, in his *Vines and Vine Culture*, says that the Vine does best on the long-rod method of pruning. Mr. ROBERTS, gardener, of Charleville Forest, Ireland, exhibited in 1877 a bunch of Gros Guillaume weighing 23 lb. 5 oz.; and Mr. McKenna, gardener at Phoenix Park, Dublin, showed a bunch of 20 lb. weight; see *Gardeners' Chronicle*, 1886, Feb. 6, p. 168.

BRITISH ENTERPRISE?—At this season of the year, particularly, we receive very numerous English business catalogues, and a large number of Continental and American lists. The Continental lists, especially the German and the Dutch, are either wholly written in English, or a translation of the vernacular is given, so that a young gardener desirous of improving his knowledge of foreign languages might do worse than take these catalogues as a useful aid. This, of course, is not the primary object of these lists. Their main aim is to convey information to potential purchasers, and so the compilers adopt means to bring the descriptions of what they have to offer for sale under the notice of their customers in the easiest way, without inflicting on them the trouble and loss of time involved in translating. In many cases our Continental friends take the trouble (which must be great to them) of making use, for our benefit, of our senseless system of weights and measures, and our incoherent money tables. No doubt the foreign merchants find it remunerative to take all this trouble, and it is really very

ind of them to do it for us. What surprises us is that our business men so rarely do the same; indeed, we do not remember to have seen a seed or plant catalogue from a British firm in any other language than English, nor one in which the prices and quantities were expressed in terms that would be readily intelligible outside his country from one end of Europe to the other without the trouble of translating or calculating.

THE EFFECTS OF EARTHQUAKE ON TREES.—Two or three correspondents of *Indian Gardening* say that since the earthquake in June the fruits on their Papaw-trees have not increased in size nor ripened, but remain in the same state as before the earthquake. New growth, however, and a fresh crop of fruit has been produced since the catastrophe, leaving the previously-formed fruit arrested.

SALPICHRON RHOMBOIDEUM.—Under the name of Muguet des Pampas (Lily of the Valley of the Pampas), M. GERARD, in the *Revue Horticole*, speaks of a Solanaceous plant called under the above name, and erroneously under that of Withania origanoides. M. GODEFROY-LEBEUF writes of it as a highly ornamental hardy climber, fit for covering trellises and the like, suitable for towns, for the country, for the seaside, for all descriptions of soil, and for all aspects. The berries are about an inch long, oblong shape, and of a whitish colour—whence the popular but paradoxical name “Œufs de Coq” (Cock's eggs).

ACREAGE OF CROPS IN THE UNITED KINGDOM.—According to the Returns of the Board of Agriculture, the following is the total acreage of the United Kingdom, including the Isle of Man and Channel Islands, and of the crops therein cultivated during the present year, 1897:—

Acres.	
77,671,319	... Total area of land and water.
47,888,653	... Total acreage under all kinds of crops, bare fallow, and grass.
3,390,092	... Corn crops.
4,337,568	... Green crops (including 1,194,194 Potatoes).
4,152,796	... Clover, sainfoin, and grasses under rotation.
27,924,710	... Permanent pasture or grass, not broken up in rotation.
46,995	... Flax.
50,869	... Hops.
7,345	... Small-fruit.
405,282	... Bare fallow.

ALGERIA.—We take the following from a letter in a recent number of the *Times*:—“What is the condition of Algeria? The Sugar-cane has no sugar, it is inferior Bamboo. The Coffee-berry is empty. The cotton is too short for spinning. The cocoa-Palm is incapable of bearing fruit. The Indigo plant comes to nothing. The Pine-apple does not ripen. A hot-house is necessary for the Vanilla. Of spices we had better not speak; there is nothing here to compare with Brazil or India. And for European products it is still worse. Corn becomes hard in the third year; a mealy Potato is a myth. Oxen in the fourth generation dwindle from 300 kilogrammes weight to 150 lb. Fowls are poor; fruit wormy, even the Banana being pesty. True, there are a few good Oranges; but the wine is harsh and rough, the sugar of the Grape not being capable of being entirely converted into alcohol and carbonic acid. In short, there is a rebuff all along the line.” This unfortunate condition of affairs is attributed by the writer to the temperature, which is always too cold or too warm, or not cold enough and not warm enough.

Mr. JAMES SIMPSON, late of the Royal Horticultural Society's Gardens, Chiswick, has received from Mr. T. McMEIKEN, Falkland Park, South Norwood, an appointment on his tea plantations in Assam. Mr. SIMPSON entered the service of Messrs. JAMES COCKEN & SONS, nurserymen, Aberdeen, as an apprentice, and during his apprenticeship he (in 1893) received the Royal Horticultural Society's Certificate for Examination in Horticulture. During his stay in the Royal Horticultural Society's Gardens, he was for more than two years Honorary Secretary and Treasurer of the Chiswick Gardeners' Mutual Improvement Association, and held the South Kensington Science and Art Certificates in Mathematics, Drawing, and Botany. Mr. SIMPSON left for Assam on the 12th inst.

PUBLIC PARKS OF NEW YORK.—A brochure by GHERARDI DAVIS, containing information read before the New York Historical Society last April, concerning the establishment of public parks in the city of New York, is of considerable interest as a record of progress. Formerly, the need for open spaces as recreating grounds in the centre of large towns, was scarcely thought of; of late years it has received much attention. The foundation of the bowling-green, of Battery Park, City Hall Park, Madison Square, and the other open-spaces in New York, as well as the development of these pleasure-grounds, are dealt with in the little book before us. To quote from it, “New York may well be proud of the work done by the Park Department during the past twenty years, for the care which the commissioners of that department have bestowed upon our park system.”

GREENHOUSE HEATING.—“One cubic foot of gas per hour will maintain a rise of 1° Fahr. for every 450 square feet of glass on a calm day with no wind, but at least double this power must be provided for windy weather. The average working practice is 1 cubic foot of gas per hour for every 300 square feet of glass, and one-third of this extra for exposed outside walls. Greenhouses heated by gas are frequently worked so as to be very unnecessarily expensive. It may be taken, as a rule, that no plant-house heated by gas should be kept at a higher minimum than 45° Fahr. If this is strictly observed, the time during which the heat is required will not average, in the Midlands, more than a total of six to eight weeks per annum. If a higher temperature is kept, the extra gas required for the same period is not a serious matter, but the time during which the heat is required is enormously increased; a minimum of 55° would extend the time to nearly six months, and a minimum of 70° would mean hard firing, day and night, for almost the whole of the year. Inattention to this important point means excessive cost, and consequent discarding of what, under reasonable conditions, would be found a great pleasure and convenience. *The Commercial Uses of Coal Gas.*”

WOLMER FOREST AS A SANCTUARY.—Mr. THOMAS WHITBURN, President of the Guildford Natural History and Microscopical Society, writes from 36, High Street, Guildford, under date Nov. 4:—“Owing greatly to the approval of the Press, the question of the preservation of Wolmer as a sanctuary for birds is assuming national importance, and it may perhaps interest your readers to know that the petition, numerously signed by influential residents here, including some distinguished military officers familiar with the Wolmer district, will shortly be submitted to the heads of the Department of Woods and Forests for their consideration. Among those whom I have interviewed on the subject is the renowned and venerable artist, G. F. WATTS, R.A. On a visit which I paid him on Wednesday afternoon at his house, known as Limner's Lease, which he has erected some 3 miles from Guildford, near the village of Compton, he expressed warm sympathy with the movement, and said that it gave him great pleasure to sign the petition. He also, as indicating his thorough appreciation of the aims of the Guildford society, has allowed his name to be connected with it in the same manner as that of Mr. GLADSTONE—namely, as hon. member. Thus the Guildford Natural History Society can boast of the rare distinction that two of the most eminent men of the century have signified their emphatic approval of its endeavours, and given it the valuable prestige of their support.” *Times.*

VICTORIA MEDALISTS.—The last issue of the *Gardeners' Magazine* contains a double-page plate containing the portraits of all the Victoria Medalists. The likenesses are so generally good, that we congratulate our contemporary on its enterprise.

HOME CORRESPONDENCE.

THE WELLINGTONIA IN CO. WICKLOW.—The County of Wicklow is noted for the numerous fine specimens of the newer Conifers, which find a home on the sunny slopes, or in the sheltered glens of its mountain ranges. In the mild and genial climate of Ireland they seem to thrive about as well as they do in their natural habitats, on the Pacific slope of North America, and on the richly-wooded hills of far-away Japan. Fine examples of the Wellingtonia are met with in almost every domain around the numerous country seats, from Coolatrin in the south, to Powerscourt in the north, both of which are famed for their fine collections of exotic Conifers. The older and best-grown trees have in many instances reached a height of over 70 feet, with straight massive stems, often girthing, at 5 feet up, 10 to 11 feet. Two remarkably fine specimens, perhaps the finest in the county, are growing on the lawn at Fassaroo, the seat of Richard M. Barrington, Esq., about 2 miles from Bray, in the extreme north of the county, and at an altitude of some 150 feet above the level of the Irish Sea. The soil is a friable loam, of good depth, resting on an open sub-soil, and the spot is fairly well sheltered. The trees are in splendid health, straight and shapely, and richly clothed with branches from top to bottom, where they sweep the greenward. These fine trees were accurately measured this autumn, and their dimensions were found to be as follows:—No. 1, planted in 1857, height, 77 feet; girth of the stem at 5 feet up, 6 feet 3½ inches; at 3 feet up, 10 feet 2 inches; at the base, 14 feet 10 inches. No. 2 stands near to No. 1, and was planted in 1859. Its height is 73 feet, girth of the stem at 5 feet up, 11 feet 4 inches; at 3 feet up, 12 feet 7 inches; and at the base, 16 feet 9 inches. Two noble trees for any lawn, and few finer specimens are seen in any part of Britain. *D.* (See p. 379.)

AGARICUS PROCERUS.—In these days of fungus forays, can any of your correspondents tell me if they have seen of late years many of the *Agaricus procerus*? It used to be tolerably abundant in a rough pasture here, but it has been very scarce of late, and this year has not appeared. Its characteristic form, and the peculiarity of its ring, make it a very distinct species; and in delicacy of flavour and substance, it, to my mind, far surpasses the common Mushroom, *A. campestris*, of which we have fewer than usual this year, but what we have had were extraordinarily large—Horse-Mushrooms, as the country people often call them. *R. Milne-Redhead, Clitheroe.*

EARLY NESTING OF A ROBIN.—It may be of interest to your readers this week to note that in a stable adjoining the gardens here a robin has recently built a nest, and deposited five eggs—a most unusual occurrence. *H. Warren, Aston Clinton, Aylesbury.*

ROSES.—When provoked by the absence of reference to fragrance in your publication on the subject of Roses, I wrote (as published in your issue of July 3) about fragrance in Roses deserving, or rather requiring, separate sections in nurserymen's catalogues, for varieties possessing this attribute, on account of the great preponderance of numbers of modest admirers that would primarily look for fragrance as the first attribute. I had hoped that, on their behalf, the discussion would have been extended. But I presume your journal has numbers of subscribers who are exhibitors of Roses, and that their number far exceeds that of the more modest class (?), so that nothing came of it at the time. I am therefore doubly pleased to have such a valiant ally in the least expected quarter, viz., “Wild Rose,” in your last week's number, outstripping, at a bound, my comparatively humble suggestion by seriously proposing that non-fragrant Roses be suppressed. Certainly! whole measures are best. I make bold therefore to suggest also that Roses of the graceless stiffness of the Baroness Rothschild class should by our hybridisers be sought to be replaced by grace in habit, so that with fragrance combined we may strive to arrive at perfection for the whole class. I will remember a severe rebuke received from one of the first Rose-growers of the realm on my ordering, some fifteen years ago, a fresh selection of new Roses, if his firm would only send such as were severely fragrant—the reply being to the effect that they had no time for such triviality! Why should not the National Rose Society agree to offer special prizes for collections of the greatest fragrance, and as “Wild Rose” proposes, not award any honours to Roses

deficient in perfume. Surely fragrance is the poetry of the Rose, as "Wild Rose" aptly suggests. *H. H. R., Forest Hill.*

CARNIVOROUS SLUGS.—Would it not be better to call these "worm eating slugs?" *Testacella haliotidea* (to which my experience is confined, for no one has asked me to name *T. Maugeli*) may be proved to be worm-eating by immersing them in weak salt and water. Dr. Ball records that "by putting them into spirits they disgorged more of these animals than I thought they could possibly have contained; each worm was cut, but not divided, at regular intervals." I fancied this cutting had been done by the horny jaw in the upper part of the mouth, which most Limaces have. But Mr. Ralph Tate asserts that this and other predaceous pulmonifera "do not possess horny jaws." This wants investigation. Mr. Tate also says that, "The food of the young *T. haliotidea* consists of small worms, and the white slender vermiform animals which live upon putrefying vegetables." *W. T., Bishop's Teignton.*

THE IRISH HEATH, which the older botanists know as *Menziésia polifolia*, was, according to Mr. W. J. Bean, changed in 1834 to *Daboecia polifolia*, because the plant was known in the west of Ireland as St. Daboo's Heath. Surely the generic name ought rather to have been *Dabécia*, not *Daboecia*! *W. T., Bishop's Teignton.* [The *Index Kewensis* retains the original but incorrect spelling. It does not adopt the anterior name *Borretta* (1790), which has lately been revived. In our opinion, it is best to take the *Kew Index* as the standard, and to leave to monographers the onus of changing nomenclature, even if we know it to be incorrect. *Ed.*]

THE MILD AUTUMN.—It is interesting to read the reports from different parts of the country on the mildness of the weather. Things are much the same here in south Worcestershire. We have been up to this date picking well-ripened Tomatoes from plants growing on the garden walls. Kidney Beans, Vegetable-Marrows, Dahlias, Gladiolus, and many tender annuals are beautifully in flower in the borders; and there are Strawberries of good size on some of the early varieties, but these fruits are not likely to ripen, the air being very humid. The mean temperature of October was 50.3°, which is 4° above the mean for that month here. The mean of the maximum readings was 58.0°, and that of the minimum 42.7°. The highest day reading was 65.7° on the 17th, and the lowest night reading 33.0° on the 6th, the lowest registered here this autumn. These readings are from the screen and Kew-tested thermometers. The rainfall was 1.33 inches, which is below the average. The day temperature of the present month has ranged between 44.9° and 60.9°, and the nights from 37.2° to 53.3° up to the 15th inst. The lawn grass is still growing, and will need mowing if the weather should continue mild. Since the above was written, we have registered 1° of frost. *W. Burgess, Bredons Norton.*

— *Plants in bloom at Shirenewton Hall, Chepstow.*—*Plumbago* *Larpenæ*, *Rudbeckia* *subtomentosa* and *speciosa*; *Asters* *Thomsoni*, *bessarrabicus*, *horizontalis*, and *Mrs. Thielton Dyer*; *Geranium striatum*, *Endresii*, *Robertianum*, *R. album*, *Chrysanthemum latifolium* *Duchess of Abercorn*, *segetum*, and *leucanthemum*; *Hypericum olympicum*, *Campanula isophylla*, *Celsia arcturus*, *Erigeron mucronatus*, *Tritoma Uvaria grandis*, *Choisya ternata*, *Althæa Baldwinensis*, *Hydrangea japonica*, *Anemone japonica pallida*, *Tradescantia virginica*, *Bidens tripinnata* and *grandiflora alba*; *Tagetes pumila erecta*, *T. patula*, *Jasminum nudiflorum*, *Lobelia erinus*, *Salvia coccinea* and *patens*, *Ligustrum japonicum*, *Arbutus Unedo*, *Spiræa Barmaldæ*, *Agrostemma coronaria*, *Cheiranthus Harpur Crewe*, *Godetia The Bride*, *Mignonette Victoria*, *Golden Queen*, and *Mecanopsis cambrica*; *Gynurum argenteum*, *Achillea Millefolium*, *Ruta graveolens* *variegata*, *Primula vulgaris* (both yellow and white), *Lavandula spica* (Glasnevin form), *Borago officinalis*; also *Roses*, *Antirrhinums*, *Calceolarias*, *Corn-flowers*, *Helichrysums*, *Ten-week Stocks*, *Carnations*, garden *Peas*, *Polyanthus*, *Violas*, *Violets*, *Fuchsias*, *Laurustinus* (single and double), *Daisies*, and *Dahlias* (show, fancy, single, Cactus, and hybrids). I have never recorded so many as late as November 22. We have had no frost severe enough to cut Dahlias. *E. J. Lowe.*

FLOWERS STILL BLOOMING IN THE PEAK.—*Shirley Poppies*, *Cornflowers*, *Mignonette*, *Candy-tuft*, *dwarf and tall Antirrhinum*, *Dahlias*, *Helichrysus monstrosum*, *Lavatera rosea splendens*, *French Marigolds* (dwarf and tall, in abundance), *Tagetes pumila*, *Godetias*, *Nasturtiums*, *Convolvulus minor*,

Viscaria, *Eschscholtzia*, yellow *Marguerites*, *Anemone japonica*, *Hollyhocks*, *Gladiolus Brechleyensis*, *Chrysanthemums*, *Pentstemons*, *Carnations*, *Pansies*, *Violas*, and *Roses* in profusion. I may add, the gardens here are about 900 feet above sea-level, and most of the flower borders are facing east. Many of the above species of flowers I am still cutting for decorative purposes. *C. B., Eyam, Derbyshire, Nov. 22.*

LAW NOTES.

RATING OF HORTICULTURAL PROPERTIES.

THE case of *Ayers v. The Dartford Union Assessment Committee* was heard recently at the West Kent Quarter Sessions.

Mr. Castle said the points upon which the appeal was made were based mainly upon the interpretation of the Agricultural Rates Act, 1896, and the question for the Court to determine was, whether, under the recent Agricultural Rates Act, appellant was not entitled to be assessed for his greenhouse property at Sutton-at-Hone, at a lower rate than the Assessment Committee had seen fit to impose. The property in question existed on certain land in the parish of Sutton-at-Hone, and comprised fifty-nine glasshouses belonging to the appellant, Mr. Ayers. Now, the question was, what was the amount to put on the property at a valuation such as would represent a proper value? The figures put on were £201 and £194, and these sums it was contended should be reduced to £201 11s. gross, and £140 net; off that other sums should be taken, and that, on the ground of the appeal, should reduce the totals to £193 gross and £132 net. The real question now with regard to the glasshouses was, whether the rating should be on the basis of 6 per cent. and 4 per cent., or 7½ per cent. and 5 per cent.

Mr. James Benjamin Slade, F.S.I., a member of the firm of Protheroe & Morris, auctioneers, &c., 67 and 68, Cheapside, E.C., was first called. He said he had had a long experience in valuing, selling, and letting horticultural properties, extending over a period of twenty years. Dealing with property of the kind in question was a special feature of the firm's business. He had made a survey of Mr. Ayers' property, and had checked the plan showing how the houses were laid out. He had made a careful inspection of all the houses, with a view to arriving at the value of the property. To get at the structural value, he adopted the principles and custom of his firm. He produced a statement showing the details. The structural value of the glass-houses he set down at £2998 11s., or in round figures £3000. The actual ground covered was 94,889 square feet. He made allowance for pathways between the houses, and thus brought the total ground covered to nearly 3½ acres. His valuation he brought out at £193 gross, and £132 nett. In making his calculations he looked rather more at the nett than the gross. He had come to the conclusion that it would be an impossibility to let the nursery at more than 4 per cent. net on their structural value, the tenant doing the repairs. That would work out at £132, and that, in his opinion, was the best rent that could be obtained; and if Mr. Ayres wanted to let, the probability is that he would have to wait a considerable time before he got a tenant. It would not be possible to get more rent than that.

Mr. Dickens: Would it not be possible to get £185?

Mr. Slade: No. It would be absolutely impossible. The keenness of the competition has much to do with the valuation. It is common knowledge that the Channel Islands have considerably forced the hands of the British horticulturist. Grapes are being sold now 66 per cent. less than they were ten years ago. It comes to this, that market gardeners will have to bring themselves to sell their Grapes at 1s. per lb. before long, or else give up the business of growing them altogether. Difficulties are increasing every way; there are great difficulties with regard to railway transit, although in the district under notice the London, Chatham & Dover Railway do their best. It has been proved to be cheaper to bring goods from France to London than from Swanley to London.

Cross-examined by Mr. Dickens: Witness said there were fifty-nine glasshouses; the last was built in 1891, and the first in 1886. A landlord would have to be satisfied, if he wished to let, with 4 per cent. on his outlay for greenhouses. A glasshouse was of no real value to anyone excepting those who had a proper use for it. There was more risk attaching to such a thing than to a house or factory.

Mr. Dickens: Then that being so, a man would expect a higher percentage to make up for the risk?

Mr. Slade: Well, he would not get it. Continuing his evidence, witness said he had put the structural value of the greenhouses in round figures at £3000. Whatever way the same property might have been valued by others, he claimed that the manner in which he had carried out his valuation was the correct one.

Re-examined by Mr. Castle: Witness said he adhered to his statement that it would be very difficult to get more than 4 per cent. His figures were supported by his estimate, and he was corroborated in the neighbourhood as to what had taken place. He could refer to property belonging to Mr. Nash. In his opinion £140 would be the full letting value of the property in question if it was in the market. He had had ample experience in that direction. Four years ago he valued the whole of the nurseries in the Bromley Union, comprising seventeen parishes, and this year he had been engaged on twenty cases in Brentford.

Mr. William George Cooke, A.R.I.B.A., P.A.S.I., of 85, Walbrook, a surveyor under appointment of the Board of Trade,

said he had inspected the property forming the subject of that appeal. He made his total value £3200. He worked on the 6 per cent. scale to get the gross annual value. The total gross value he put down at £201, and the total net value at £134. There was a cottage in connection with the property, but that was assessed separately.

Mr. Ayers, the appellant, was called. He produced the accounts for the last seven houses he built. The amount came to £80 8s. 8d.

For the respondents it was submitted that the assessment by the Dartford Union Assessment Committee was a fair and just one.

Mr. William Eve, F.S.I. (W. Eve & Son, 10, Union Court, Old Broad Street, E.C.), stated that he had been thirty-nine years in practice. He had gone carefully into the matter in detail, and had measurement taken of the various buildings, and plans prepared showing sections of the greenhouses. He estimated the rateable value of the glass erections and trade buildings, with 3½ acres of land, £209 10s., as follows:—

59 Greenhouses	£190 0
Well, Wind Motor, Reservoir, and Pipes	£10 0
Packing Shed, Wagon, and Empty Shed	£10 0
Stable	£70 0
Land, 3½ acres	£10 10
	£290 10

He considered that 5 per cent. on the structural value was the proper way to estimate the net rateable value.

The Court, after a brief deliberation, allowed the appeal with costs, and reduced the assessment to £235 gross and £159 net. The Justices agreed to state a case for the opinion of the High Court on the question as to whether or not market or nursery-gardens, with glasshouses erected on them, are to receive the allowance of 50 per cent. off the rates in accordance with the provisions of the Agricultural Rates Act, 1896. *Condensed from the "Estates Gazette."*

DENDROBIUM CŒLOGYNE.

THIS remarkable species was described by Reichenbach in the *Gardeners' Chronicle*, February 4, 1871, p. 136, and from that time to this, probably not twenty collections can boast of having had a plant of it. A specimen was exhibited by Messrs. Hugh Low & Co., of Upper Clapton, at the Royal Horticultural Society on Oct. 23, 1894, and this served as a model for the accompanying wood-cut (fig. 114), which shows the somewhat awkward habit of the plant. The flowers, which seem to be produced singly from the apex of the pseudo-bulb, are by no means small for a *Dendrobium*, although they present a different aspect from most of the larger-flowered kinds. They are greenish-yellow in colour, the inner surface being decorated with rows of deep purple lines and blotches. The large three-lobed lip is marked in the same way, but is of a conspicuous satiny brownish-black colour, and the column, which is shown between the two narrow projecting petals, is streaked with purple. One of the chief peculiarities of this species consists in its creeping rhizome, on which the old angular bulbs are about 2 inches apart. The plant is a native of Moulmein, and, like so many other Orchids of that region, was discovered by the Rev. C. Parish. *John Weathers.*

SOCIETIES.

ROYAL HORTICULTURAL.

NOVEMBER 23.—An ordinary meeting of the committee of this Society took place at the Drill Hall, James Street, Westminster, on Tuesday last, in most unpleasant weather. The atmosphere was laden with fog throughout the day, varying in degree a little at different periods. The hall was only imperfectly illuminated by gas, and the colours of the flowers, as described in the report below, are as nearly correct as we could estimate them in such circumstances. The display upon entering might easily have been mistaken for a *Chrysanthemum* show, exhibits of this popular flower absorbing so much of the space occupied. Of the six Awards of Merit granted by the Floral Committee, five were to *Chrysanthemums*. Orchids, however, are ever present, and this Committee were not without subjects presented for examination. Beyond these there were groups of *Begonias* and *Euphorbias*, each of which were exhibits of excellent culture. Two collections of Apples, and one of large Onions, a new Apple, and a new Grape, were the principal exhibits before the members of the Fruit Committee.

Floral Committee.

Present: W. Marshall, Esq., chairman; and Messrs. C. T. Drury, H. B. May, R. Dean, Geo. Stevens, Jas. Hudson, Thos. Peed, R. B. Lowe, H. J. Cutbush, J. D. Pawle, Jas. Walker, C. E. Shea, Charles Blick, Hy. Turner, R. M. Hogg, and Chas. Jefferies.

Messrs. JAS. VEITCH & SONS, Ltd., Royal Exotic Nursery, Chelsea, exhibited a few plants of *Begonia* *Mrs. Heal*, a figure of which may be seen on reference to the *Gardeners' Chronicle*, p. 585, vol. xviii., 1895. The variety was obtained from a cross between *B. socotrana* and a tuberous-rooted variety. *B. Mrs. Heal* commences to grow about July, and flowers until Christmas, in an intermediate house. The plants shown afforded evidence of its deco-

relative value at this season. The flowers are scarlet, or rosy-scarlet. Messrs. VITCH also showed a new Begonia named *Julius*, obtained from a similar cross: in this case the tuberous parent was a rose-coloured variety. *B. Julius* has double, bright rosy-pink flowers, very pretty in bud, and adaptable for button-hole adornment. It is free flowering, and has deep green foliage (Award of Merit).

Messrs. W. CORBUSH & SON, Highgate, London, had a group of *Palma*, and a number of seedling varieties of *Fernettia mucronata* (Silver Banksian Medal).

Messrs. HUGH LOW & CO., Clapton and Bush Hill Park

Tunbridge Wells, who had an exhibit of fifty plants or more. These were in 5-inch pots, and varied from 1 to 2 feet in height had retained their foliage well, and carried very large bright coloured bracts. This group was encircled with a few dwarf decorative plants (Silver Banksian Medal).

Mr. A. TULLER, Swanley, showed sprays of a semi double scarlet-flowering zonal *Pelargonium*, described as a sport from *Raspall Improved*. It is brighter in colour, and the flowers are larger than those of that well-known variety.

Bunches of a white-flowered single *Chrysanthemum* were shown by Mr. H. BACKER, Jersey. The flowers had suffered

antherum Mrs. H. Folkes, shown by Mr. H. Folkes, gr. to C. E. STRACHAN, Esq., Hemel Hempstead. It is a large, rather flat flower, pure white, with stout stems that require no support.

Twelve blooms of incurved *Chrysanthemum* Mrs. W. C. Egan were shown with others from Mr. R. OWEN, Maldenhead. The flowers are pale-coloured with white centre (Bronze Banksian Medal).

Mr. N. MOLYNEUX, gr. to J. C. GARNIER, Esq., Rookesbury Park, Fareham, obtained the Society's Award of Merit for his seedling Japanese variety, *Mary Molyneux*. This has been described frequently. The three blooms exhibited on this occasion were very large, but inclined to be rough.

Mr. W. J. GODFREY, Exmouth, Devon, showed several *Chrysanthemum* novelties, including *Lady Northcote*, white Japanese, assuming colour with age; *Mrs. Peabody*, an incurved; *Mrs. Molling Grant*, reminding one of *M. Chenon de Leché*, but different in colour, being pale reddish. Mr. GODFREY also showed several varieties of winter-flowering *Carnations*, and some cut blooms from *Sweet Pea*, var. *Celestial*, cut from a plant growing in a very exposed situation.

Mr. H. J. JONES, of the Ryecroft Nursery, Lewisham, made a most tasteful exhibit of cut *Chrysanthemums*, appropriating for this purpose one of the long central tables in the Hall. There was a great number of flowers in this exhibit, but no mass of colour. Some of them were displayed in handsome vases, others in stands and similar devices. The boxes, however, were not obtrusive, owing to a skilful disposition of pretty *Palma*—*Cocos Weddelliana*, and *Ferns*, which also served to break up and relieve the mass of flowers. Some of the varieties shown were the following, and it will be seen that many of them were novelties: *Mons. Deblanc* (incurved), *Western King* (represented in several dozens of good blooms), *Mrs. G. W. Palmer*, *Mrs. R. Jones*, *Yellow Madame Carnot*, *Australia*, *N. C. S. Jubilee*, *Mrs. A. H. Wood*, *W. Wright* (a very fine dozen), *Ma Perfection*, and *Duchess of Fife* (both incurved), and many unnamed Seedlings (Silver-gilt Flora Medal).

Another large exhibit of *Chrysanthemums* was one from Mr. W. WELLS, Earlswood Nurseries, Redhill, Surrey. This exhibit was a most representative one, and included varieties of every type. Three Awards of Merit were also made to varieties in Mr. Wells' collection. These were to *Georgina Pitcher*, Japanese, extra wide florets, slightly incurved, occasionally twisted, and pleasing shade of yellow. To *Scaramanga*, a large and very deep Japanese flower, pale reddish colour and buff; and to *Mrs. F. A. Bevan*, one of the most delicately coloured Japanese *Chrysanthemum* flowers, medium size, of good depth, florets very smooth, and flowers generally of a refined appearance.

Some late-struck plants of the variety *Scaramanga* in 6-inch pots were also shown, bearing blooms almost large enough for exhibition. Amongst a number of other varieties in this collection, the two most deserving of comment are *Earlswood Beauty*, a white, single-flowered variety, of first-class value, and *Madame Feriot*, a very fine white incurved flower (Silver-gilt Banksian Medal).

A collection inclusive of about forty bunches of *Chrysanthemums*, was shown by Mr. A. H. RICKWOOD, gr. to the Dowager Lady FREAKE, Fulwell Park, Twickenham, and a Silver Banksian Medal was deservedly awarded.

An exhibit of floral arrangements suitable for the embellishment of the dinner-table, made by Mr. L. H. CALCUTT, Fernbank Nursery, Fairholt Road, Stoke Newington, N., was awarded a Silver Medal. The display was intended to illustrate certain flower stands made of gold-coloured, twisted wire in the form of arches and other devices, some simple, others more elaborate. Generally, they were light and pretty, the simpler stands especially.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. JAS. O'BRIEN (Hon Sec.), De B. Crawshaw, S. Courtauld, T. Statter, H. Ballantine, F. Sander, H. M. Pollett, A. H. Smee, W. H. Young, H. J. Chapman, and E. Hill.

Messrs. JAS. VITCH & SONS, Ltd., Royal Exotic Nursery, King's Road, Chelsea, were awarded a Silver Flora Medal for a very pretty group composed chiefly of rare hybrids. Of these, making their appearance for the first time, were *Cattleya* × *Empress Frederick* var. *Leonate* (Mosses ♀, *Dowiana* ♂), a very handsomely-coloured form of the hybrid shown by Messrs. Veitch in 1892, and which had white sepals and petals. The present fine variety somewhat resembles *C. x Hardyana*, but has a broad circular fronted lip; sepals bright rose; petals dark rose, changing to light lilac towards the much crimped margin; lip yellow at the base with dark crimson lines, the front being rosy-crimson; flower very fragrant (Award of Merit). *Lælia* × *Olivia* (*xanthina* × *crispa*), a neat and novel flower with yellow sepals, and petals slightly tinged with red; lip yellow at the base, soft rose with some obscure yellow veining in front (Award of Merit). *Cypripedium* × *Alonso* (*Spicerianum* × *Arthurianum pulchellum*), in which the upper sepal was white marked with purple, the remainder of the flower resembling some forms of *C. x Leeanum*. Also in the group were *Lælia* × *Cattleya* × *Stutteriana*, *L. C. x Decia*, *L. C. x Semiramis*, *L. C. x Palas*, *L. C. x Tiresias*, *Cattleya* × *Mantini*, *Cypripedium* × *Leeanum* varieties; *C. x Actæus*, *C. x Prospero*, *C. x Euryades*, *C. x Robert*, *O. x Nobe*, *J. x Phæra*, *C. x Io grand*, *C. x Genone*, *Zygopetalum Mackayi*, *Epidendrum Wallisi*, &c.

Messrs. HUGH LOW & CO., Clapton, secured a Silver Flora Medal for a very bright group, in the centre of which was *Vanda coerulea*, and around it a dozen fine and distinct varieties of *Cattleya labiata*, also a form of *Cypripedium*.

FIG. 114.—*DENDROBIUM CECYLOGYNE*. (SEE P. 386.)
(Flowers greenish-yellow; lip brownish-black; and the column streaked with purple.)

Nurseries, exhibited a group of flowering-plants, composed of the winter-flowering, fibrous-rooted *Begonia Gloire de Lorraine*, and some plants of a new scarlet, winter-flowering *Carnation*.

An exceedingly commendable exhibit of *Begonia Gloire de Lorraine* was made by Mr. F. CUBBERLEY, gr. to J. W. FEARLE, Esq., Leyswood Gardens, Groombridge. This included about forty plants in 5 and 6-inch pots, well grown, and abundantly flowered, and the flowers were of capital colour. These excellent decorative plants were interspersed with a few *Palma* and *Ferns* (Silver-gilt Banksian Medal).

An object-lesson in the culture of *Euphorbia* (*Poinsettia*) *puleherrima* was furnished by Messrs. T. CRIPPS & SONS,

considerably, but beyond a very free blooming habit, the variety may not be exceptional.

From Messrs. VILMORIN, ANDRÉUX & CO., Paris, came a few plants of *Primula obconica*, scarcely so well flowered as they are usually seen here.

CHRYSANTHEMUMS.

Five bunches of *Chrysanthemums*, in as many varieties, were sent by M^{rs}. ANATOLE CORDONNIER, Bayonne, France. The committee passed a Vote of Thanks for them, the varieties being of ordinary merit, so far as could be judged from the specimens.

An Award of Merit was granted to white Japanese *Chry-*

× Conco-laure, the massive C. × Prewetti, of unknown parentage, but with evidence of C. villosum as one of the parents; C. × Sallieri Hyacum, C. × ananthum superbum, varieties of C. × Lecanum, C. × Enfieldense, some good Odontoglossum crispum, Oncidium Forbesii, O. pretextum, and a pretty lilac-coloured Cattleya Bowringiana.

The Right Hon. JOSEPH CHAMBERLAIN, Highbury, Moor Green, Birmingham (gr., Mr. Smith), was awarded a Silver Banksian Medal for a small stand of excellently grown hybrid Orchids, viz., Lallo-Cattleya × Clive (C. Dowiana × L. pumila prestans), a grand hybrid raised by Norman C. Cookson, Esq. In the present high state of cultivation, it showed its distinctness from L. C. × Ingrami (L. Dayana × C. Dowiana aurea) very plainly, especially in its larger size and brighter colouring; L. C. Gottleiana (C. labiata × L. tenebrosa), a grand flower, partaking much of L. tenebrosa in form, but of a clear, soft rose-colouring, the front of the lip being rose-purple; L. C. × Ophelia (C. Bowringiana × L. C. elegans), sepals and petals bluish-white, front of the lip purple; Cattleya × Miss Williams (Harrisoniana × Gaskelliana); Lallo-Cattleya albanensis, and L. C. × Corbeillensis.

Messrs. F. SANDER & Co., St. Albans, staged an effective group, in which were Maxillaria elegantula, Rolfe, n. sp., a pretty species, near to M. fucata, illustrated in the *Gardeners' Chronicle*, November 17, 1888, p. 577; its flowers were white, tinged with yellow on the outer halves, and spotted with chocolate colour (Botanical Certificate); Phallo-Calanthe × Arnoldiae, with pretty pink-tinted flowers; Phaius × Ashworthianus, with yellow flowers, the lip of which was marked with dark purple; Calanthe × Florence and C. × bella; Chondrorhyncha Chestertonii, Cymbidium × Winnianum; varieties of Cypripedium × Lecanum, and other Cypripediums; Dendrobium Johnsoniae, and Habenaria carnea (Silver Banksian Medal).

Baron Sir H. SCHRODER, The Dell, Egham (gr., Mr. H. Ballantine), showed Odontoglossum Dayanum, said to have been so named by Professor Reichenbach, with fine large cream-white flowers profusely spotted with cinnamon-brown. It very closely resembled O. prestans, figured in the *Lindleya*, vol. vii., p. 71 (Award of Merit).

W. P. BURKINSHAW, Esq., West Hill, Hessele, near Hull (gr., Mr. J. Barker), showed Cattleya labiata White Queen, a pure white variety, with a very faint trace of pink on the lip (Award of Merit).

Messrs. LINDEN, l'Horticulture Internationale, Parc Leopold, Brussels, showed Cypripedium × Beekmanii (Boxalli superbum × bellatulum), the largest and most beautiful of its section. Its massive flower had the dorsal sepal of a bright emerald green, profusely spotted with black, and edged with white; petals very broad, chestnut-red, margined with yellow, and with some purple spots on a light ground at the base; lip chestnut-red margined with yellow—the whole flower having a highly polished-looking surface. As with the fine C. × Lucienianum, which somewhat approaches it in form, the use of C. bellatulum as one of the parents was doubted by most of the members of the committee. In any case, it is a grand flower (Award of Merit). Messrs. Linden also showed the clear yellow and white C. insignis Luciani.

R. L. MEASURES, Esq., Cambridge Lodge, Flodden Road, Camberwell (gr., Mr. J. H. Chapman), showed the singular Cirriopetalum refractum (oft n. called the Windmill Orchid), with a nodding raceme of golden yellow flowers, the dorsal sepals of which formed the conspicuous part. The flowers were arranged round the spike, so as to be sensitive to the slightest current of air, and formed an attractive curiosity (Botanical Certificate). Mr. Measures also showed Cypripedium × Saron (niveum × (?) venustum Measuresianum), with white flowers tinged with emerald-green, and profusely spotted with purple.

W. B. LATHAM, Esq., Botanic Gardens, Edgbaston, Birmingham, sent Cypripedium × Deedmanianum (Spicerianum × Chamberlainianum), a pretty hybrid having the upper sepal white, with a green base, and a median line of purple, on each side of which were some lighter purple spots; petals yellow tinged with purple; lip rose with yellow margin. The flower so closely resembled the C. × Haynald-Chamberlainii, shown at the last meeting, as to raise doubt as to the record of that hybrid being correct; otherwise it may be that the individuality of C. Chamberlainianum is so pronounced as to allow of but little variation in the progeny, even when widely separated species are employed.

The Hon. P. ALLSOPP, Battenhall Mount, Worcester (gr., Mr. Fox), sent a fine plant of Cypripedium insignis Vigoriana, a peculiar variety in which the spotting usually seen in the species was wanting.

PHILIP CROWLEY, Esq., Waddon House, Croydon (gr., Mr. Harrie), showed a good form of Cattleya labiata and C. l. roses, the latter with very brightly-coloured flowers, the front of the lip bearing an irregular blotch of crimson.

W. H. LUMSDEN, Esq., Balmiedie, Aberdeen (gr., Mr. Roberts), sent varieties of Cypripedium insignis montanum, including one clear yellow form, near to C. l. Ballie.

Captain HOLFORD, Westonbirt, Tetbury (gr., Mr. Chapman), sent cut Orchids, including Odontoglossum Andersonianum, Zygopetalum crinitum, Cypripedium × Lecanum giganteum, and varieties of C. insignis.

Fruit Committee.

Present: P. Crowley, Esq., chairman; and Messrs. Jos. Cheal, A. F. Barron, A. H. Pearson, P. C. M. Veitch, Alex. Dean, J. W. Bates, G. T. Miles, C. Herrin, G. Reynolds, F. Q. Lane, Jas. Smith, S. Norman, J. Willard, and Robt. Fife.

Messrs. T. RIVERS & Sons, Nurseries, Sawbridgeworth, Herts, exhibited six baskets of Apples taken from trees

cultivated in pots under glass, the varieties being Ribston Pippin, beautifully coloured, and for the variety large fruits; Cox's Orange Pippin, equally fine and good; Buckingham, a showy fruit of oblate shape, with deep basin round the eye, and skin of a rosy-red on the sunny side, and pale yellow elsewhere; Peasgood's Nonsuch, of extraordinary high colour, and above the average in size; King of Tomkins County, a fine high-coloured form of this favourite American Apple, with the colouring disposed more in streaks than as broad patches; Bijou, a small, pretty, smooth-skinned, crimson-skinned fruit (Silver Banksian Medal).

Messrs. RIVERS showed black Grape Directeur Tisserand, an apparently long-keeping variety, of nice flavour, oval in form of berry, a moderately thick skin, with plenty of bloom upon it. We believe it has been shown several times at the Royal Horticultural Society's meetings (an Award of Merit). Another Grape shown by them was Gradiška, a Hungarian variety of no part cular merit, with oval white berries.

Thirty dishes of very excellent Apples, in as many varieties, came from the gardens of C. LEE CAMPBELL, Esq., Gileston Court, Ross, Herefordshire (gr., Mr. Bayford). These consisted of popular varieties of mostly more than average size, of high colour generally, and clear of skin—a very nice collection. Especially fine were Fearo's Winter Nonsuch, Glria Mundi, Besspool, Emperor Alexander, Golden Noble, and Cox's Pomona (Silver Banksian Medal).

Mr. E. Beckett, gr. to Lord ALDENHAM, Aldenham Park, Elstree, Herts, showed seven heaps of Onions, of very large size, viz., Alls Craig, Anglo-White Spanish, Green's Prize-taker, Cranston's Excelsior, Cocoonut, Sutton's A1, and Barnet Hero (Silver Banksian Medal).

The Apple Competition resulted in Mr. Woodward, gr. to ROGER LEIGH, Esq., Barham Court, Maidstone, taking 1st for Cocker Pippin; and Mr. Bayford, gr. to C. LEE CAMPBELL, Esq., Gileston Court, the 2nd, with Cox's Orange Pippin.

The Pear Competition was decided in favour of Mr. J. Crook, gr. to W. H. EVANS, Esq., Forde Abbey, Chard, with Winter Nellis; Mr. WOODWARD being 2nd, with Nouvelle Fulvie. The number of dishes shown on this occasion was very small.

Mr. CHAMBERS, Beech Farm, Mereworth, Maidstone, received an Award of Merit for a seedling Apple named Lady Falmouth, the fruit resembling in general appearance Devonshire Quarrenden. As regards its flavour, we are unable to speak.

Mr. Batchelor, gr. to Lieut.-Col. VERNON, Harefield Park, Uxbridge, showed a dish of the Cape Gooseberry (Physalis peruviana), and received a Vote of Thanks.

Apple Reinette Superfin was shown by Messrs. J. JEFFRIES & SON, Nurseries, Cirencester, a large-ribbed, somewhat conical-shaped fruit of a crimson colour on the sunny side. It was unnoticed by the committee.

HORTICULTURAL CLUB.

NOVEMBER 9.—The usual monthly dinner and conversation took place at the rooms of the Club, Hotel Windsor, on the above date. The chair was occupied by the Rev. W. WILKS, and notwithstanding the attractions of the Chrysanthemum, there was a good attendance of members, amongst whom were Messrs. Shea, Selge Leonard, C. E. Pearson, A. H. Pearson, G. Buyard, George Nicholson, G. Massee, James H. Veitch, and the Secretary.

The discussion was opened by Mr. G. MASSEE, President of the Mycological Society, who gave a very interesting address on "Lilies and their Diseases," and a very instructive and practical conversation followed, in which most of the members present joined. A cordial Vote of Thanks was accorded to Mr. Massee for his valuable address. We give an outline of it, which, however, only gives a faint idea of its value.

Among the various fungous diseases to which Lilies are subject, three kinds require special notice, on account of the wholesale destruction caused by their presence. One of these, unfortunately too well known in this country, especially during damp seasons, first appears under the form of small, yellowish spots on the leaves and flower-buds; these spots soon change to a dark olive-green colour, and if a fragment of the fungus taken from one of these spots is examined under the microscope, it is seen to consist of a number of dark coloured threads, each bearing two or three clusters of spores or "conidia" near the tip. These conidia are produced in rapid succession during the summer months, and are capable of germination the moment they are ripe. The conidia are readily distributed by wind, insects, or rain, which carries them from diseased to healthy leaves. All conidia alighting on the damp surface of a Lily leaf or flower germinate at once, enter the tissues of the plant, and form new centres of disease, which quickly produce fresh conidia. From the above account, it will be readily understood how easy, and also certain, it is for the disease to spread rapidly after it has once gained a foothold in a bed of Lilies. At this stage spraying with a fungicide is of great service in preventing the spread of the disease, as all germinating conidia are destroyed. A solution of potassium sulphide, in the proportion of 1 oz. of the sulphide, dissolved in 8 gallons of water, serves the purpose. During the summer the mycelium of the fungus becomes aggregated into numerous minute, compact, black lumps, or sclerotia, in the tissues of the leaves, stem, and often also in the outermost bulb-scales. As the leaves and stems decay during the winter, the sclerotia are liberated and lie on the ground, where they remain in an unchanged con-

dition until the following spring, when they produce conidia, which find their way on to the leaves or flowers of Lilies, and the disease commences its life-cycle anew. From what has been said, it is scarcely necessary to indicate the importance of not allowing leaves and stems of diseased plants to decay on the ground; all such should be collected and burned. All bulb-scales showing the minute black sclerotia imbedded in their tissue should be removed before the bulbs are planted. The conidial form of this fungus is called Botrytis; it is probably a stage in the life-cycle of a higher form called Sclerotinia, but this has not yet been definitely proved.

A second disease, caused by a fungus called Phyllosticta lillicola causes the appearance of reddish patches on the stems and leaves of Lilies, followed by a bronzing of the leaves; the flowers of such plants are usually distorted, or not unfrequently fall in the bud stages. Promptitude in spraying on the first appearance of the disease would check its spread, and the burning of all diseased stems and leaves would tend to prevent a recurrence of the disease.

A third disease, which has during the past two years proved most disastrous to the bulb industry in Japan, is known as Rhizopus necans. To the naked eye this fungus presents the appearance of numerous miniature pins, with round black heads springing from a white down felt of mycelium. The minute black heads contain numerous conidia, and such of these as alight on any injured portion of a bulb, germinate at once, enter the tissues, and eventually kill the bulb. In addition to conidia, a second form of fruit is formed by the fungus in the tissues of the decaying bulb; these remain in a resting condition until the following spring, when they produce conidia, by which the crop of bulbs is again infected. The fungus cannot enter the unbroken tissues of a bulb, but gains access through some wound, usually broken root-fibres.

It has been shown that bulbs are much more susceptible to the disease when lifted before they are quite mature. Furthermore, such bulbs are usually packed for exportation before they are dry, consequently sweating takes place during the journey, and all the conditions tend to favour the development and spread of the disease.

A full account of this disease, along with illustrations, is given in the *Kew Bulletin*, February—March, 1879.

HAMMERSMITH HORTICULTURAL.

NOVEMBER 11.—The thirteenth Chrysanthemum show held in the newly-opened Hammersmith Town Hall was the best of the series of exhibitions that this society has as yet held. The removal of the show to a more central spot, and where sufficient space was obtained to display the exhibits to advantage, was quite a step in the right direction. The society has only to make itself better known, not a difficult operation in these days, and offer sufficiently good prizes in the future, in order to induce more spirited competition, the life of such gatherings.

In the gardeners' class for a group arranged for effect, the 1st prize was obtained by Mr. LLOYD, Merton Lodge, Chiswick, with a pretty contribution; 2nd, Mr. F. HOODLESS, Chiswick.

In the amateurs' division for a similar group, the principal prize-winners were Messrs. THOMPSON, CLARKE, and WOODHOUSE.

Cut blooms.—In this section, the most noteworthy exhibit was comprised in the fine Japanese and incurved flowers exhibited by Mr. P. BOSANQUET, gr., Pontfield, Herts, which easily secured the special prize in the open class.

Quite the feature of the show was a very fine group of foliage and flowering plants sent (not for competition) by Messrs. WILLS & SEAGAR, South Kensington. Mr. J. J. HILLIER, Hammersmith, sent a good collection of Apples.

CHESTER PAXTON.

NOVEMBER 16.—The seventh show of Chrysanthemums and fruits was held in the Town Hall. The Assembly Room, in which the exhibition was held, presented a very pleasing appearance, the Chrysanthemums and fruits having been arranged with taste.

Among the exhibits in the fruit section was one from the Duke of WESTMINSTER, Eaton Hall (Mr. Barnes, gr.), who sent a meritorious collection of sixty dishes of Pears and Apples. Next to this the most conspicuous collection was that from Mr. JOHN WATKINS, Pomona Farm, Withington, Hereford, who was represented by fifty dishes of Apples, the colour of some of which was excellent. Mr. LYLE SMYTH, Barrowmore (Mr. Morris, gr.), and Mr. E. PAUL, Graysfield, Barrow (Mr. Fletcher, gr.), were local competitors showing in this class.

Messrs. DICKSONS, Limited, again occupied the whole length of the lower end of the room, with an imposing and miscellaneous exhibit of flowers and fruit. The exhibit contained excellently grown specimens of Chrysanthemums, Cyclamens, Carnations and Palms, the front being finished off by luscious-looking fruits from the Upton and Newton Nurseries. Section A was open to professional gardeners, and the classes for dessert Apples were noticeable. In the single variety class, the Rev. L. GARNETT, an old and successful exhibitor was 1st; Mr. SAUNDERSON, of Bodnant, who showed a capital dish of Ribston Pippins having to be content with 2nd place.

Miss HUMBERSTON, Newton Hall (gr., Mr. Wakefield), took premier award for Cox's Orange Pippin. Other successful exhibitors in these classes included Mrs. PORTS, Hoole Hall (Mr.

J. Taylor, gr.); the Hon. C. T. PARKER, Eccleston; Mr. B. C. ROBERTS, and Mr. T. R. FLEMING, Rowton Grange. The kitchen Apples also made a capital show.

Turning to Section B, Mr. JOHN WYNNE, Waverton, secured 1st honours for Ribston Pippins; while in the Cox's Orange Pippin class, Mr. J. JEFFERSON, Pool Hall, was 1st. Mr. WILLCOCK, Handbridge, and Mr. JOSEPH SUCH, Davenham, Mr. THOMAS HATFIELD, and Mr. JEFFERSON also carried off several awards in the classes for Apples and Pears.

A new departure was made in the arrangement of the Chrysanthemum classes, the groups of plants being in the centre of the room instead of at the sides. The alteration added greatly to the general attractiveness of the exhibition. The entries were made in this class by the same five exhibitors as last year, when Mr. J. WYNNE FROULKES, Old Northgate House, took 1st prize. Mr. WYNNE FROULKES repeated his success this season, the other four groups, however, being also of excellent merit.

A new feature in the Chrysanthemum classes was that for an epergne filled with such of those flowers as are suitable for table decoration. Nine competitors entered in this class, and although Mr. EDGE, of Hoole Bank, is not perhaps so advantageously placed as the others, he managed to carry off the 1st prize in the face of strong opposition.

The class for the six best specimen plants of Japanese varieties did not obtain so many entries as could have been wished, but the quality was very good, the 1st prize blooms from Mollington Hall (Mr. WORKER) being almost perfect.

WIMBLEDON HORTICULTURAL.

NOVEMBER 16, 17.—Chrysanthemum shows evidently have their seasons of flux and efflux, and the one under notice is a case in point, as last year the exhibition was of very moderate character; whereas, this year it showed great improvement. It also had the benefit of being held in the roomy Drill Hall. There was, however, room for greater competition, and this fact points to the conclusion that such shows are far too numerous.

Cut-blooms.—There were but two competitors in the chief class for thirty-six blooms, half Japanese, half incurved, Messrs. Hunt, gr. to PASTIA RALLI, Esq., Ashted Park, and Mr. GIBSON, gr. to J. WORMALD, Esq., Morden Park. The prizes went in this order, Mr. HUNT's blooms being excellent in both sections. The same competitors were in the same order in the class for twelve Japanese, repeats of flowers previously seen largely.

In a similar class for Japanese, Mr. J. FRENCH, gr. to Mrs. BARCLAY, Wimbledon, was 1st, with very good blooms; Mr. SKEGGS, gr. to Mrs. DUNN, Wimbledon, 2nd. With twelve incurved blooms, Mr. FRENCH was again 1st, but Mr. ALDERMAN was 2nd. In the class for six Japanese, Mr. H. A. NEEDS, Woking, was 1st with capital blooms; and with six incurved blooms, Mr. FRENCH was 1st.

Plant Groups, &c.—The best miscellaneous group, very bright and pleasingly arranged, came from Mr. NEWELL; Mr. CHANDLER, gr. to the Rev. Canon HAYGARTH, being 2nd.

With Chrysanthemum groups, very much of the usual semicircular and flat-faced order, Mr. D. GIBSON, gr. to J. B. JOHNSTONE, Esq., Kingston Hill, was 1st, the front view of the plants being anything but pleasing.

Fruit.—Competition in Grapes was limited, the Whites being presented by Messrs. ALDERMAN and by Mr. Methven, gr. to W. KEILLER, Esq., Wimbledon Park, both being moderate exhibitors of Muscats of Alexandria. With Blacks the position was reversed, both having creditable Alicantes, but Mr. Methven had the finest berries.

Mr. ALDERMAN put up a long and very elegantly-arranged collection of hardy fruits, with table-plants and cut flowers interspersed, producing a most pleasing effect.

FOLKESTONE AND DISTRICT CHRYSANTHEMUM.

NOVEMBER 16, 17.—This show took place, as usual, in the Palace Gardens Theatre, the large ante-room being filled with plants, and an inner room with a large number of cut flowers and vegetables. The quality of the cut flowers was much in advance of that of last year, and in all the leading cut flower classes there was spirited competition. Several were open classes, and some of the leading growers in the southern district entered for competition.

The leading class was for twenty-four blooms, twelve Japanese and twelve incurved, some good stands competing, the best coming from Mr. A. BUTCHER, gr. to C. J. BISS, Esq., Smooch. His leading Japanese were J. Seward, Madame Rogain, Madame Carnot, Oceana, Edith Tabor, Mutual Friend; and his more prominent incurved, Lord Rosebery, Bonnie Dundee, Miss Phyllis Fowler, Alfred Salter, Empress of India, Mrs. R. C. Kingston, and C. H. Curtis. 2nd, Mr. W. Frost, gr. to G. ASHBY TODD, Esq., Ashford, whose best incurved were Lord Alcester, Bonnie Dundee, Jas. Agate, Violet Tomlin, Mrs. R. C. Kingston, Triomphe d'Eve, C. H. Curtis, and Lyne, Jr. There were some very fine Japanese also.

Mr. H. SHOOTSMITH, nurseryman, Woking, had the best twelve Japanese, a very fine lot, the leading flowers Mrs. J. Lewis, Australia, Oceana, Mutual Friend, Midlle Lawrence, Zede, Mrs. H. Weeks, Lady E. Saunders, Australian Gold, &c.; Mr. T. COTTERELL, gr. to Sir W. GEARY, Bt., Tonbridge, was 2nd, having also some very fine blooms, chief among them Mrs. C. BLOK, International, M. Pankowcke, Mutual

Friend, Edwin Molyneux, Souvenir d'une Petite Amie Niveaux, and T. Wilkins.

With twelve incurved, Mr. BUTCHER was again 1st, having in very fine character Duchess of Fife, Bonnie Dundee, Violet Tomlin, John Lambert, D. B. Crane, Triomphe d'Eve, and C. H. Curtis; Mr. TODD was again 2nd, having a fine bloom of Harold Wells in his lot.

The best twenty-four blooms (open only to gardeners' societies in Kent), was won by that of Ashford, Mr. BUTCHER contributing some very fine Japanese and incurved; Mr. TODD was placed 2nd. There were several other classes for cut blooms, but the foregoing were the leading ones.

The culture of specimen plants is not well carried out at Folkestone; in most of them could be seen somewhat poor blooms on indifferently-grown plants. Groups of Chrysanthemums arranged for effect resulted in the judges having to put plants carrying the finest blooms last, growth and grouping alike being defective.

The best group of miscellaneous plants came from Mr. GEO. MOUNT, of Canterbury and Folkestone, seasonable flowering and foliage plants of good quality being intermingled. Mr. G. PILCHER, nurseryman, Folkestone, was 2nd.

In the centre of the main hall was a very fine group of plants from Mr. GEO. MOUNT. Mr. H. CANNELL, Swanley, had a very attractive table of cut blooms of Chrysanthemums, zonal Pelargoniums, Violets, &c.; and Mr. A. WILSON, decorative florist, Folkestone, a large table of floral decorations.

Vegetables were numerous shown, and altogether the results were decidedly satisfactory.

LICHFIELD CHRYSANTHEMUM.

NOVEMBER 17, 18.—The fourth annual exhibition was held in the St. James' Hall, Lichfield, on the above dates, the opening ceremony being performed by J. COURTNEY WARNER, M.P. The show in all departments was an excellent one.

Amongst the non-competitive exhibitors were J. COURTNEY WARNER, M.P., who sent a collection of Orchid and other flowers; Mr. T. WALMSLEY, City Seed Stores, Lichfield, who contributed cut flowers, and fruit and vegetables; Mr. F. BARRANCE, a collection of Chrysanthemums and other plants; Mr. T. W. BROOKS, cut flowers and table-plants; Mr. W. LITTLE, cut flowers; Mrs. CHADWICK, Hints Hall, table-plants and Chrysanthemum blooms. Messrs. PERKINS & SONS, Coventry, a fine display of bouquets and other floral designs. Mr. W. F. GORDON, Stowe, had the best group of Chrysanthemums, and the best group of miscellaneous plants.

The finest dozen blooms of Japanese Chrysanthemums were shown by Mrs. CHADWICK, Hints Hall; the next in point of merit being those from Sir CHARLES FOSTER's garden.

Mr. R. P. COOPER, Shenstone Court, had the finest half-dozen cut blooms of Japanese; and the finest dozen of incurveds, also the finest half-dozen, came from Mrs. CHADWICK's garden.

Mrs. BAGOT LANE, Kings Bromley Hall, had the best half-dozen of Anemone-flowered blooms.

The table-decoration of Chrysanthemums, set up by Miss SWINTON, of Lichfield, were adjudged to be the finest, and in the best taste.

A few plants of Chrysanthemums in competition, and small quantities of fruits and vegetables, made up the exhibition.

RUGBY CHRYSANTHEMUM.

NOVEMBER 17, 18.—This Society held a very successful show, in which the classes were well contested, especially those for cut blooms.

For a group of Chrysanthemums in a space of 50 square feet, G. A. SCOTT, Esq., The Lawn, Rugby (Mr. Maunse, gr.), was 1st, with a well-arranged group of finely-grown plants.

In the class for four trained specimen plants, Mr. CALDSWOW was 1st, and his best blooms were Chas. Davis and Vivand Morel.

Mr. CALDSWOW was 1st for one single plant of Mrs. William Holmes.

For twenty-four cut blooms, the 1st prize and N.C.S. Certificate were won by A. JAMES, Esq., Cotton House, Rugby (gr. Mr. A. Chandler); he had twenty-four first-class blooms of the following varieties:—Madame Carnot, Oceana (very fine in colour), Silver King, Mutual Friend, Hairy Wonder, M. Pankowcke, John Seward, M. Chenon de Leché (one of the best blooms in the show), Simplicity, Richard Dean (fine in colour), Modestum, Duke of York, &c. A. MUNTZ, Esq., Dunsmore, Rugby (gr. Mr. J. Blakenby), was 2nd, who had Madame Carnot, very good.

For eighteen Japanese blooms, Mr. JAMES was again 1st, A. MUNTZ, Esq., 2nd.

Mr. PEARCE, Weedon, was 1st for twelve Japanese blooms, and for twelve incurved blooms.

Fruit.—For two bunches of Grapes, Earl DENBIGH was 1st, with well finished bunches of Muscat of Alexandria; the Earl FERRERS was 2nd.

Apples and Pears were very good, considering the season, the principal prize-winners being Earl DENBIGH and Mr. CORRY, the best specimens of Pears being Beurré Bachelier and Beurré Diel.

Vegetables were a marked feature in this show. Table decorations, bouquets, and baskets of Chrysanthemums were numerous, and Mr. ROBINSON, of Rugby, was the chief winner in these classes.

A stand was provided for surplus flowers, fruits, and vege-

tables, presided over by ladies, the proceeds of which will be given to the Gardeners' Orphan Fund. Last year a balance of over £6 was sent to the Fund.

HULL CHRYSANTHEMUM.

NOVEMBER 17, 18.—For many years Hull has held a Chrysanthemum show of the very first rank. To this Society belongs the credit of introducing the system of displaying the plants in groups, interspersed with foliage-plants; and the groups at the Hull shows have always held a foremost position. Many societies have since adopted the practice, or endeavoured to improve upon it, but even now there are nowhere such groups to be seen as those at Hull. Cut blooms, too, are exhibited at Hull in as fine quality as at any other place in the United Kingdom. The management is excellent, and the Hon. Secretaries, Messrs. Dixon and Harland, are the very men for the position. The show is held annually in the Artillery Barracks; and although the building, with its three side rooms, affords much space, its limits are taxed to the utmost by the exhibits.

Groups being a most noteworthy feature, deserve a prior notice. A Silver Challenge Vase, valued at 25 guineas, along with a cash-prize of £6, was offered for a group of Chrysanthemum plants interspersed with foliage plants and arranged for effect in a space of 100 square feet. This year there were four competitors, and arranged as they were, at the sides of the principal hall, a grand display was made.

The judges awarded the 1st prize to the exhibit belonging to the Hull Corporation, and as this body could not accept a prize, the award fell to the next in point of merit—that arranged by Mr. G. Wilson, gr. to Sir J. RECKITT, Swanland Manor, Brough, which was only a trifle inferior to that previously named. The group arranged by Mr. Wilson was composed of fairly good Chrysanthemums, associated with magnificent Crotons, Palms, and other foliage plants, notably a variety of Marantas, all of which, being set on a green base, could be distinctly seen. The back of the group, which was semi-circular in form, with two abutting semi-circles in front, was fully ten feet high; and taken as a whole, it was a magnificent display. Mr. G. Jarvis, gr. to Mrs. WHITTAKER, Cliff House, Hessle, was a good 2nd, with finely-flowered Chrysanthemums and good foliage plants, but they were too closely placed at the front. Prizes were offered also for a group of miscellaneous plants arranged for effect in a space of 100 square feet; here Mr. G. WILSON was successful, winning the premier award with a really good arrangement of suitable plants. Mr. JARVIS was 2nd. For a decorated drawing-room mirror or panel group of Chrysanthemum plants, interspersed with foliaged plants arranged for effect in a space of 9 square feet, Mr. LEADBETTER took premier position, with a bold, effective group of well-flowered Chrysanthemums, Dracenas, &c.

Specimen Chrysanthemums made a bold display, being numerously staged. For six trained plants, Mr. H. Thompson, gr. to C. J. RINGROSE, Esq., The Grange, Cottingham, was an easy winner, with good plants. Mr. Thompson also won premier award for three standards, all of the Rundle type.

Bush-grown yet not formally-trained plants were well represented by Mr. W. GOODHILL, 54, Trinity Street, Hull.

An interesting class was that for "cut-back" Chrysanthemums, six plants, to be judged by their quality of bloom, with dwarfness of growth, and good foliage. Mr. V. Waterhouse, gr. to U. T. OWBRIDGE, Esq., Cherrygarth, Cottingham, won with plants well developed in bloom and foliage; Mr. E. WEST, The Nurseries, Cottingham, was 2nd.

Plants in the amateur classes were best shown by Mr. ROBERT THURSK, Grovehill Road, Beverley, and in all classes they were meritorious.

CUT-BLOOMS.

For twenty-four incurved, there were six competitors, the 1st place being taken by Mr. C. J. SALTER, gr. to J. B. HAYWOOD, Esq., Woodhatch, Reigate, with medium-sized, well-finished blooms of leading varieties. Mr. LEADBETTER was a good 2nd; and W. MEASE, gr. to A. TATE, Esq., Downside, Leatherhead, 3rd.

For twenty-four Japanese distinct, Mr. MEASE won easily with grandly developed blooms of the best varieties; Mr. SALTER being 2nd.

The best six blooms of one variety (Japanese) were staged by Mr. SALTER, the variety M. Chenon de Leché being shown in grand condition.

Anemone-flowered varieties were well represented. The dozen blooms shown by Mr. SALTER were quite of the best class, as also were the reflexed and Pompon varieties.

Chrysanthemums in baskets or vases were well shown by Mr. G. Wilson and Mr. F. MASON, gr. to A. SMITH, Esq., Woodleigh, Hessle. The former had exceedingly fine examples of both incurved and Japanese in separate baskets. The latter staged all Japanese; both were good exhibits, and won premier award in their respective classes.

Single-flowered varieties made a bright display, and were much admired. Mr. WATERHOUSE won, with a grand stand of blooms.

Table decorations at this show are very fine. These, arranged in a room under artificial light, made an attractive display.

Mrs. F. S. WHEELER, "Chepstow," Prince's Avenue, Hull, won the Challenge Plate, value ten guineas, for a dessert-table, 8 feet by 4 feet, with a pleasing arrangement of bronze and yellow Chrysanthemums, lightly arranged with Fern-grasses, &c.

Mrs. F. TOPHAM, Hotham Hill, Brough, won the premier award for a similar table with a tasteful arrangement.

BRISTOL CHRYSANTHEMUM.

NOVEMBER 17, 18.—This Society held its thirty-fourth exhibition in the Colston Hall, and it was a remarkably successful one, the number of exhibits being considerably larger than was the case last year, and the quality was generally of high excellence.

The class for a group of Chrysanthemums was won by J. DOLE, Esq. (gr., Mr. J. Marshall), with plants having large blossoms and good foliage, all Japanese varieties; S. C. GODWIN, Esq. (gr., Mr. McCollock), who was a close 2nd, had some incurveds among his plants.

In a class for groups of Chrysanthemums arranged with Ferns and ornamental foliage plants, the competition was very keen, and E. S. GEORGE, Esq. (gr., Mr. Ross), won 1st prize.

For a bank of miscellaneous plants, 10 feet by 5 feet, Chrysanthemums excluded, J. SANDERS, Esq., was an easy 1st, with a beautiful arrangement.

Trained plants, both standards and dwarfs, exhibited skilled culture, Mrs. GIBSON (gr., Mr. Ayres), Major-Gen. DAUNT, and E. P. MARTIN, Esq., being the leading prize-winners.

In certain classes devoted to them, Orchids were shown well, and they were one of the most brilliant features of the show.

Cut-blossoms.—Ten exhibitors staged in the class for thirty-six Japanese blossoms. Lady THEODORA GUEST (gr., Mr. Wilkins) taking premier honours with grand and fresh flowers; Mr. DRAKE of Cardiff, was good in 2nd place.

For thirty blossoms, incurved, Sir C. PHILLIPS, Picton Castle (gr., Mr. Dumble), was 1st with large and well-finished flowers; W. M. BAKER, Esq. (gr., Mr. Applin), was placed 2nd with equally well-finished but somewhat smaller blossoms.

For twelve blossoms, Japanese.—1st, R. A. BOWRING, Esq. (gr., Mr. H. A. Joy); and for two ve Japanese incurved, Mrs. H. SMITH secured a similar position. There were eight collections of good blossoms in the latter class.

Floral wreaths, bouquets, sprays, &c., were shown in great numbers. Mr. WINSTONE, Miss BASH, C. DODSON, C. LOW, Mr. W. TRESEDER, Mr. FISHER, and Mr. COLES being the chief prize-winners.

Specimen Ferns were shown best by Mr. BANNISTER, who was 1st for six plants.

MISCELLANEOUS.

Mr. GODFREY, Exmouth Nurseries, exhibited fourteen dozen Chrysanthemum blossoms in splendid condition, including most of the new varieties for which he has taken certificates at the National Chrysanthemum Society's exhibitions. He also showed eighteen varieties of Carnations, one named Exmouth Scarlet, being a fine full flower of good substance.

Messrs. JAS. CARTER & Co., London, staged a large collection of vegetables.

YORK FLORISTS'.

NOVEMBER 17, 18, 19.—The above Society held its eighteenth Chrysanthemum and fruit show in the Fine Art Exhibition. Although the entries were more numerous than last year, the tables did not appear so well filled, especially in the hardy fruit section, but the quality of the fruit and vegetables was good.

In the class for a group of Chrysanthemums, interspersed with foliage plants, there were three entries, the 1st prize of £10 and a Gold Medal being won jointly by Mr. R. McIntosh, gr. to J. T. HINGSTON, Esq., York, and Mr. G. COTTAM, who were declared equal. Mr. McIntosh's was a very light arrangement, but rather flat; while Mr. Cottam trying, apparently, to guard against this evil, obtained a result that was rather top-heavy.

For a group of Chrysanthemums arranged for effect, Mr. D. DICKINSON, gr. to W. B. RICHARDSON, Esq., was 1st, his plants being very clean and fresh looking; Mr. E. EVERARD, gr. to Mrs. GUTCH, was 2nd.

For thirty-six cut blossoms, inclusive of eighteen incurved and eighteen Japanese, Mr. J. FOLKARD, gr. to Sir JAMES R. WALKER, was 1st, his incurveds being particularly fine; amongst the Japanese, Madame Carnot, Mdle. Hoste, and E. Molyneux were best. To this prize of £10 is added the Citizen's Challenge Prize, value £20. Mr. Goodacre, gr. to the Earl of HARRINGTON, was 2nd, his Japanese blossoms being very good.

Mr. FOLKARD was again 1st for eighteen incurved blossoms, and for twelve incurveds. In the former class, Mr. G. ANDERSON, gr. to A. MILNETHORPE, Esq., was 2nd.

Mr. WILLIAMS, gr. to the Earl of FAVERHAM, was 1st for eighteen Japanese blossoms, and for twelve Japanese; Mr. PICKER, gr. to F. R. PEASE, being 2nd in each instance.

For six white Japanese, Mr. FOLKARD was 1st; and Mr. WILLIAMS was 1st for six blossoms of any variety not white, with Viviani Morel. In this stand was shown the premier Japanese bloom.

For six golden-yellow Japanese blossoms, Mr. WILLIAMS was 1st with Thos. Wilkins.

For the most tastefully arranged epergne for dinner-table, Messrs. R. SIMPSON & SONS were 1st; and Mr. W. BONSALE was 1st for a hand-bouquet of Chrysanthemums.

The best basket of Chrysanthemums was one from Messrs. R. SIMPSON & SONS.

There were numerous entries for a vase of Chrysanthemums and foliage, arranged for drawing-room decoration, and Mr. A. LUND, gr. to Lord HERRIES won.

Fruit.—In the class of six bunches of Grapes, Mr. J. ALLSOP, gr. to Lord HOTHAM, was 1st with Mrs. Pearson, Alicante,

and Muscat of Alexandria. We are accustomed to seeing good Grapes from this exhibitor, but never previously has he staged better fruit than his bunches of Black Alicante on this occasion. Mr. J. TULLET, gr. to Lord BARNARD, was 2nd.

For two bunches of black and two of white Grapes, Mr. ALLSOP was again 1st.

In the class for a collection of dessert fruits, six varieties, Mr. ALLSOP was 1st with Black Alicante and Mrs. Pearson Grapes, Ribston Pippin and King of the Pippin Apples, Duchess and Doyenne du Comice Pears. In this class Mr. ALLSOP beat Mr. J. TULLET, and Mr. J. McIndoe, gr. to Sir J. W. PEASE, Hutton Hall, Guisborough, who were 2nd and 3rd respectively.

Vegetables were never better shown, and the prizes offered for collections by Messrs. SUTTON & SONS and Messrs. JAMES CARTER & Co. were well fought for.

MANCHESTER ROYAL BOTANIC.

NOVEMBER 18, 19, 20.—In the hurried report published in our last issue of the Chrysanthemum Show held under the auspices of this society, notes upon the following non competitive exhibits were inadvertently omitted. The exhibition was a very fine one.

Messrs. DICKSON, BROWN & TAIT and Messrs. DICKSON & ROBINSON, both Manchester firms, staged collections of remarkably well-grown Cyclamens of good strain.

Messrs. W. & J. BIRKENHEAD, Sale Nurseries, put up a large collection of choice varieties of Ferns.

Mr. JOSEPH BROOME, of Llandudno, sent a large collection of cut flowers obtained from the open; also some cut specimens of Arbutus (Strawberry-tree) bearing numerous handsome fruits.

Messrs. HUGH LOW & Co. staged a valuable and distinct collection of hybrid Cypripediums, amongst which were C. x Mrs. Fred Hardy (First-class Certificate), and Calanthe Veitchii alba (Award of Merit).

Messrs. W. L. LEWIS & Co. showed about thirty magnificent forms of Laelia pumila, var. prestans, representing very valuable forms and colouring, several being worthy of varietal names. Cattleya labiata Lewisii, recently shown in London, was also an attractive plant.

Mr. FRED HARDY, of Tyntesfield, put up a group of choice Cypripedium hybrids, various forms of insignie, all of which were meritorious.

Mr. W. OWEN, Northwich, also exhibited Cypripediums, principally the montana form of insignie, some of which were very distinct.

NORFOLK AND NORWICH HORTICULTURAL.

NOVEMBER 18, 19, 20.—This Society was established in 1829, and it holds two or three exhibitions each year. The Society has a reserve fund of nearly £200, and it is the Chrysanthemum show especially which helps to make the Society so financially prosperous. On this occasion, despite the gloom outside, St. Andrew's Hall was aglow with brilliant tints. The fruit and some miscellaneous plants filled a large ante-room, and a large tent erected outside the hall contained the vegetables, for the whole space of St. Andrew's Hall was required for the Chrysanthemums.

Specimen plants were a great improvement upon those of last year, and much better than anything we saw at Hull; they were bush grown, with excellent foliage, and fine heads of bloom.

Mr. J. G. SELLING, Norwich, was 1st, and Mr. WILLIAM BIRKBECK, Thorpe, 2nd, with six Japanese.

Mr. SELLING was 1st for six incurveds, also with reflex 1, and with three Pompons, being the only exhibitor; but all were decidedly good. Mr. F. RANDALL was awarded a 2nd prize for six Pompons.

Other plants included Cyclamens, Chinese Primroses, zonal Pelargoniums, &c., and there were effective groups of plants in two or three classes.

Some very fine collections of forty-eight blossoms of Japanese were shown, the best coming from Mr. HANSON, gr. to Sir S. CROSSLEY, Bart., M.P., Somerleyton Hall, Suffolk. Among the newer varieties were G. J. Warren, Phoebe, Edith Tabor, Madame Carnot, Mrs. C. Bilek, General Roberts, Eva Knowles, Duchess of York, and others; depth, freshness, and colour were seen in this collection. Mr. MUSK, gr. to Lord DE RAMSAY, Haveringham Hall, was a good 2nd.

The best thirty-six blossoms, eighteen incurved and eighteen Japanese, came from Mr. C. H. WATTS, the former of which were very good, including C. H. Curtis, Major B. Maillon, Bonnie Dundee, Perle Dauphinoise, and others. Mr. B. E. FLETCHER was 2nd also with good incurved.

Mr. JOHN JEFFREY, gr. to Sir R. P. BEAUCHAMP, Bart., was 1st with twenty-four Japanese, there being a very keen competition. Mr. PETRE, Westwick House, being a close 2nd.

The class for thirty-six blossoms, three each of twelve varieties, brought some very fine blossoms from Mr. H. OGLE, gr. to the Marchioness of LOTHIAN, but they were staged low, and largely light in tint. Mr. PETRE was 2nd. Most of the exhibitors ranged their blossoms in diagonal lines, which we thought imparted to the stands a confused appearance.

There was a good competition in the class for six blossoms of Japanese. The best White shown in sixes was Madame Carnot, some very fine flowers were staged; the best six of any other colour was Phoebe. Mr. HANSON had the best stand of twelve varieties introduced since 1893, Phoebe, G. J. Warren, Madame Carnot, Edith Tabor, and others of recent introduction being in good character.

Mr. HANSON had the best twenty-four incurveds, winning easily; Mr. W. HATHORPE, Cambridge, had the best twelve; while there was a brisk competition with six blossoms. The best six of any one variety of incurved was C. H. Curtis, from Mr. HANSON.

Some very good anemone-flowered varieties were shown by Mr. J. A. KENDROW and Col. ROUS in twelves; Mr. W. HATHORPE taking the 1st prize with six. Col. ROUS had a collection of Pompon varieties, the best we have seen this season, not only taking the 1st prize for twelve bunches, but securing also one of the Certificates of the National Chrysanthemum Society as a special award. Reflected blossoms were also seen in good condition.

Fruit was somewhat sparingly shown. Mr. B. E. FLETCHER had the best collection of six varieties.

The display of vegetables was very extensive, and remarkably good. Messrs. Sutton & Sons, Reading; Daniels Bros., of Norwich, and others, offered prizes for their specialties, and they were numerous shown.

Miscellaneous collections of cut flowers were staged, especially by Mr. J. GREEN, Norfolk Nursery, Dereham, who had many fine novelties. Messrs. DANIELS BROS. had two effective stands, one of plants and flowers, and another of fruits and vegetables.

STOCKPORT CHRYSANTHEMUM.

NOVEMBER 19, 20.—The tenth show of fruit and flowers was held on the above date in the Volunteer Armoury. The exhibition was the best that the Society has yet had, and therefore a very fine one. The groups of plants this year were circular, and they were placed along the centre of the hall.

For the best group of plants a Silver Cup was offered, and this was won by Captain T. H. SYKES (Mr. J. Roderick, gr.), Chingle House, Cheshire. His group was well arranged; a graceful Kentia Palm formed the centre-plant, then the Chrysanthemums, finished off with Ferns and small foliage-plants; ABEL BUCKLEY, Esq., was 2nd (Mr. W. Hough, gr.).

In the group of miscellaneous plants arranged for effect, also placed in the centre of the hall, the same exhibitor held the same positions.

Of specimen plants of Chrysanthemums, the chief exhibitor was G. H. GADDUM, Esq. (Mr. Bradburn, gr.), who showed splendid plants of Chas. Davies, Viviani Morel, Marie Hoste, and others, with fifteen or sixteen fine flowers, almost equal to exhibition quality.

There were five competitors for six table plants, and all were good, the 1st prize being won by G. H. GADDUM, Esq.

The chief interest lay in the cut-bloom competitions. A Silver Cup was offered for the best twelve incurveds and twelve Japanese, and was taken by R. W. HARTLEY, Esq., Bampton Bryan Hall, Hereford (gr., Mr. J. Robinson), who had fine blossoms of many novelties; Capt. T. H. SYKES was 2nd.

Amongst local exhibits, JAS. WATTS, Esq. (gr., R. MacKeller), Abney Hall, Cheshire, obtained three 1st prizes, which included a Silver Cup and a Silver Medal. His best bloom was Madame Gustave Henry, which was selected by the judges as the finest bloom in the exhibition.

There were other less important classes for Chrysanthemum blossoms, and several competitions in fruits and vegetables.

Mr. ROBERT HOLLISTER is the Hon. Secretary, and to his efforts was largely due the very successful exhibition.

NATIONAL CHRYSANTHEMUM.

NOVEMBER 22.—A meeting of the Floral Committee was held at the Royal Aquarium on the above date.

From Mr. H. WEEKS, The Gardens, Thrumpton Hall, Derby, came blossoms of Joseph Chamberlain, singularly bright in colour, of a brilliant chestnut with a bronzy-gold reverse; large, full, and likely to be most useful as an exhibition variety, supplying a colour much needed in stands (First-class Certificate of Merit).

From Mr. WILLIAM WELLS, The Nurseries, Epswood, Red Hill, came incurved Madame Ferlat, a large compact white flower of the shape, size, and build of C. H. Curtis (First-class Certificate); and Julia Scaramanga is a large, deep, and somewhat conical Japanese of the same shape of Madame Carnot; the colour pale reddish-orange and brown, long drooping florets at base, quite distinct and novel (First-class Certificate).

Japanese Don de la Madone, a medium-sized white variety with narrow florets, forming a dense ball-like mass, from M. ANATOLE CORDONNIER, Bayonne, France, was commended.

Incurved Mrs. A. E. Fever, dark bronze, base paling towards the centre, the reverse bright gold, a very promising variety, from Mr. A. FEAYER, The Gardens, Ash Lawn, Benenden, the Committee wished to see again.

Japanese Sarpasse Amiral, soft yellow in tint, the large incurving florets very broad, from Mr. W. WELLS, is highly promising.

The monthly meeting of the committee took place at Anderton's Hotel on the 22nd inst., Mr. T. W. SANDERS presiding. The Secretary reported that the December exhibition on the 7th proximo would be held in the Western Gallery of the Aquarium, the whole space of which would be given up for the purpose. Complaints were received as to the defective lighting of the building, and also as to the names of many of the flowers being written in pencil, rendering the deciphering of the names very difficult. The

Secretary laid upon the table a specimen of a small Gold Medal, which it is the intention of the Society to offer, and the same was approved. It was unanimously resolved that the dates of the meetings of the General Committee in 1898-9 be:—Aug. 29, Sept. 26, Oct. 24, Nov. 28, and Dec. 19, 1898; and Jan. 16, 1899. That the meetings of the Floral Committee be held at the Royal Aquarium on Tuesday, September 6, October 11, and December 6, these being show-days; and on Mondays, September 26, October 24, October 31, November 14, November 21, November 28, and December 12, the meeting-hour to be 1 o'clock on all occasions. It was resolved that the Classification Committee be instructed to meet and consider the classification of the new incurred and other Chrysanthemums, and that Mr. W. Higgs be appointed a member of the committee in the place of Mr. R. Owen, deceased. It was also resolved that this committee undertake the drawing up a list for publication, as a guide to exhibitors, of Chrysanthemums which are too much alike or may be regarded as synonymous. A motion to the effect that the November exhibition be continued for four days, with a competition on the first and third days, was defeated by a large majority. Two Fellows and sixteen ordinary members were elected, bringing the number of the latter up to 100 as elected during the present year. A vote of thanks was passed to the Chairman for presiding.

THE ANNUAL DINNER.

The members and a few friends of this society met on Wednesday evening last, at Anderson's Hotel, Fleet Street, to celebrate the principal social event of the year. Chrysanthemum growers have abundant enthusiasm, and the proceedings at the annual dinner were characterised by this desirable element. Beyond this, however, there were other circumstances that made the event this year a most pleasant one, and members who had been present at the two last dinners, were agreeably impressed in favour of the one just held.

Mr. T. W. Sanders (chairman of the general committee), made a capital president, genial, but firm, in pushing through the rather long programme. He was supported by many of the best known officials and members of the society, and for the rest, the room was as full of guests as desirable. None the less, regrets were sincere that Sir E. Saunders, the president, and Mr. J. R. Starling, who has been treasurer for so many years, were unable to be present. Immediately grace had been said, and the loyal toasts given, the chairman rose to propose that of "The Glorious Chrysanthemum and its Devotees," and in doing so, Mr. Sanders delivered a speech, in which he most eloquently pleaded the claims, virtues, and "glory" of the flower, coupling with this toast the National Chrysanthemum Society. The chairman had recently visited growers in the East End of London, and there, in the dingiest alleys, were seen plants that were given extraordinary care and attention. There, was evidence of the Chrysanthemum appealing to a class that, but for this plant, would probably have no connection with horticulture whatever.

In the suburban greenhouse, in the conservatories of the rich, and in the nurseries of the trade, when few other flowers were obtainable, and there was little sun, but much fog, were these handsome displays of Chrysanthemums. East, west, north, and south the flower had knit together every class more perfectly than any other. The National Chrysanthemum Society had contributed very largely to effect this, not only by holding exhibitions, but by disseminating useful literature upon the subject, and by affiliating societies in many parts of the globe that carried out in those parts work similar to that done here. There were now 148 affiliated societies, and ten had been added since January 1, 1897.

"The Donors of Special Prizes" was appreciatively proposed by Mr. Geo. Gordon, and responded to by Mr. P. Waterer and Mr. H. J. Jones. Mr. Waterer complained of the great noise, and of the absence of light and ventilation at the Royal Aquarium, and hoped ere long the Society would be in a position to exhibit its display in a hall more fitted to the purpose.

Referring to the great Edinburgh show, Mr. Waterer said he had gone there in preference to concentrating his efforts in London, because at Edinburgh was "the biggest thing to go for;" and he hoped that the National Chrysanthemum Society would take care that the best reward for the exhibition of Chrysanthemums offered in the United Kingdom should in future be offered in London, and by the National Society.

An interesting incident was the presentation of The Challenge Trophy, Cups and Medals, that had been won. The National Challenge Trophy was handed to J. Scott, Jun., Esq., Vice-President of the Bromley Society, who proudly accepted it for this Kentish Society, which has now won it for the second time. The blooms were contributed by ten of its members. Mr. W. Mease was greeted with cheers as he was given both the Holmes' Memorial Cups. Mr. C. Davis received the Turner Memorial Cup for his father, Mr. N. Davis of Framfield. Gold Medals were presented to Mr. H. J. Jones, Messrs. Cutbush & Sons, Mr. W. Wells, and others; and Silver Medals to various exhibitors. Mr. Mease, who had the best Japanese bloom in the show, in a bloom of a yellow variety of Madame Carnot, was presented with a painting of the flower, being a special prize by Mr. J. C. Simpson.

The officers of the Society were toasted by Mr. J. W. Wilkinson (Royal Aquarium), and Mr. R. Ballantine, and Mr. Harman Payne responded. Other toasts included "The

Chairman," "The Secretary" (Mr. R. Dean), "The Visitors," and "The Press."

In replying to "The Secretary," Mr. Dean took occasion to refer to the exceeding amount of work there was now associated with the Secretaryship, and he felt that in the near future he should have to ask the committee to relieve him of some of this. The toasts were interspersed with vocal and instrumental music.

A WORKMAN'S INSTITUTE AT TURNFORD HALL.—An institute and hall for the use of the employees of Mr. T. Rochford, at the Turnford Hall Nurseries, was formally opened on Saturday, November 20. The building consists of a dining, concert, library and reading, and committee rooms, together with sleeping accommodation, kitchen, and lavatories, and was erected by Mr. Rochford to furnish a long-felt want. About seventy persons sat down to dinner, and at the termination of which Mr. W. Long, on behalf of the members of the institution, presented Mr. Rochford with an illuminated Address in commemoration of the opening of the building.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

DISTRICTS.	TEMPERATURE.				RAINFALL.		BRIGHT SUN.	
	Above (+) or below (−) the Mean for the week ending November 20.	ACCUMULATED.			No. of Rainy Days since January 3, 1897.	Total Fall since Jan. 3, 1897.	Percentage of possible Duration for the Week.	Percentage of possible Duration since Jan. 3, 1897.
		Above 42° for the Week.	Below 42° for the Week.	Above 42°, difference from Mean since January 3, 1897.				
					More (+) or less (−) than Mean for the Week.			

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing District;—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts;—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending November 20, is furnished from the Meteorological Office:—

"The weather was in an unsettled condition during the earlier half of the period, with considerable falls of snow and sleet in the north and north-west, and a good deal of rain elsewhere. Later in the week the weather became fair and dry generally, but with local fogs and mists over England."

"The temperature soon after the commencement of the week became temporarily low in Scotland, and the change subsequently spread southwards to England and Ireland. By the 17th, however, the thermometer had risen again, and the average values of the week were above the mean in all districts, the excess ranging from 1° in 'Scotland, N.' to 4° in 'Scotland, E. and W.' and 'England, N.E. and E.' to 5° in 'England, S.' and the 'Channel Islands.' The highest of the maxima were recorded on rather irregular dates, and ranged from 61° in 'England, N.W., E., S., and the 'Channel Islands,' to 55° in 'Ireland, N.' The lowest of the

minima were registered either on the 16th or 19th, and ranged from 12° in 'Scotland, E.' (at Braemar), and from 20° in 'Scotland, N.' to 34° in 'England, S.' and to 40° in the 'Channel Islands.'

"The rainfall exceeded the mean in 'England, N.E., and N.W.,' and also in 'Ireland, S.,' but was less than the normal in all other districts. Heavy rain occurred on Tuesday or Wednesday in the south and south-west of Ireland, and at Holyhead."

"The bright sunshine was less than the mean in nearly all districts, but exceeded it in 'England, E.' The percentage of the possible duration ranged from 33 in 'England, E.' to 25 in 'Ireland, S.,' and 24 in the 'Channel Islands,' to 17 in 'Ireland, N.,' and to 8 in 'Scotland, N.'"

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

CHRYSANTHEMUM MADAME CARNOT.—I for one, says Alex. Morton, a north-country contributor, should be obliged if some successful cultivator would instruct Chrysanthemum growers the best times to strike, stop, and take the bud of the variety Madame Carnot, so that it may be in full flower by November 15. I have five plants that were treated in different ways, but they are all flowering too late. The plant No. 1 was struck from cuttings, put in November 1, 1896, grown straight on, and the crown-buds taken August 14; it is still in bud. The cuttings of No. 2 were put in November 8, pinched May 1, and the second buds taken September 1; this one has half-opened blooms, and promises well. The cuttings of No. 3 were put in November 8, the crown-buds taken August 14; this one is still in bud. The cuttings of No. 4 were put in November 8, pinched May 1, the second buds taken August 28; this one is about one-fourth expanded. The plant No. 5 was cut hard-back in the first week of May, and the first buds taken. The blooms are also very late, as there is as yet no sign of any colour. I may state that this garden is in the north of Perthshire.

Will any reader kindly afford J. J. a hint as to the cultivation and fruiting of the Custard-apple, *Anona reticulata*, described in the *Botanical Magazine* as a stove evergreen shrub?

☞ "A Subscriber—Midlands," would be glad to know what are the duties of a nursery-clerk, the kind of books he has to keep, and the best work to study on the subject of book-keeping?

ALMANACK: J. C. Most of the gardening journals publish an almanack with their first issue of the New Year: but we think that what you mean is the *Garden Annual*, or *Horticultural Directory*. The first is published at the Garden office, 37, Southampton Street, W.C.; and the other at that of the *Journal of Horticulture*, 171, Fleet Street, E.C.

BOOKS: R. B. Inexpensive books upon the culture of the Chrysanthemum have been published by Mr. Ed. Molyneux. Messrs. W. & G. Drower, Fareham; Mr. W. Wells, Karlswood Nurseries, Redhill, and others.

BROKEN FLOWER-POT: E. M. We note the neat manner in which the pot is mended; and, doubtless, many gardeners would be pleased to know what is the kind of cement used to join the pieces together, and if the cement is unaffected by moisture.

CAMELLIA FLOWER-BUDS FALLING: D. J. This may be due to a natural effort of the plant to get rid of a portion of the flower-buds when these have set very thickly; also to proximity to the heating apparatus, although this happens only during hard weather, when the hot-water pipes have to be made very hot; and it may be brought about by keeping the soil too moist at this season. The happy medium has to be struck between dryness and wetness. If the drainage be not in good order, the soddening of the soil with only moderate applications of water will soon be brought about; and in the case of large plants in tubs, it is not easy to ascertain the condition of the soil without turning the plants out of the tubs. The re-tubbing, surfacing, and other operations of that kind should be undertaken in early spring, or early in August after growth of the wood has ceased.

CAMELLIA SEEDS: *Market Study.* Sow the seeds now, in well-drained pots filled with a mixture of finely sifted loam two-thirds, peat or leaf-mould one-third, and sand sufficient to make it porous. Sow thinly, say 1 inch apart, cover with half an inch of soil, water with a fine rose can, and stand the pots in a cold pit to which the frost has not access. The soil should be kept from getting dry, and this is best done by standing the pots on the floor.

CARDIFF SHOW: A CORRECTION. It was stated in our report that the Cup, value 4 guineas, was won by Messrs. Case Bros. These nurserymen were the givers of the Cup, and the winner was Mr. Joy, gr. to R. A. Bowring, Esq.

CARNATION: B. C. M. It does not strike us as being very valuable, but as you state that it is not a representative bloom, the seedling may be worth preserving.

CHRYSANTHEMUM GOOD GRACIOUS: B. P. This is a "weak-necked" variety, and the flowers usually droop. In the case you mention, perhaps the bloom is rather less heavy than usual in proportion to the strength of stem. We suppose the plant has not "sported"?

COMMON BROOM: *Broom.* The plants may be cut down at any time from now till April.

FLOWERS OF CYMBIDIUM LOWIANUM FALLING: D. J. Flowers of Orchids fall from a variety of causes, and in winter the fog and damp are the more common ones. Very low temperature will cause the flowers to drop in the case of Orchids from tropical regions.

INSECTS: E. F. *Wills.* The insects working-up in "small heaps," between the bricks on the floor of the Mushroom-house, belong to the order Collembola, or "spring-tails," and to the genus Lipura (which is not spring-tailed); the species is probably *L. fimetaria*, but there are several very closely allied. They live under boards, in damp earth, and in manure. Their food is humus and decaying vegetable-matter, and it is doubtful if they can ever be considered injurious; but a Mushroom-bed is just the position in which a suspicion of being noxious might reasonably exist. If repeated applications of petroleum will not stop them, try strong solutions of carbolic acid in boiling-water, or cover the bricks with cement. These insects are extraordinarily prolific. R. McL.

LATIN NAMES: C. W. If you are not conversant with Latin, or the rules of botanical nomenclature, it is not surprising that you find some anomalies and much difficulty. *Berberis Aquifolium* is right; the spelling of the specific name with a capital letter denotes to a botanist the fact that aquifolium was once a generic name. Undulatum and nanum are correct in the case you mention, but if the word *varietas* or the abbreviation var. be used, then you must use the feminine undulata, nana, &c., because *varietas* is feminine. Spicata is preferable to spica, but it is generally better to retain an old name than to give a new one, hence *Cupressus Lawsoniana albo-spica* is in common use. *Ceanothus* and *Rubus* are masculine. *Macrophyllum* is applied to a plant with large leaves. *Handsworthiensis* implies that the plant was raised at or distributed from Handsworth. *Prunus triloba* is correct, *P. biferum* is incorrect; it should be *P. bifera*.

MIXED HYBRIDS OF GLADIOLUS GANDAVENSIS IN AMERICA: R. Macfee. The American gardening papers doubtless mention these plants, but we have no recollection of having seen any notes on them.

MUSHROOM BEDS: R. S. The spawn, after running, was checked in development by the dryness of the beds, and if it remains in the same condition after you have afforded water, we should imagine that your best course would be to afford a soaking of warm water, with a handful of salt to a 3-gal. water-can, well dissolved, and then applied. If this, together with a thicker covering of litter under the mats, does not induce Mushrooms to appear, nothing else will, as not only will the spawn be dead, but there will be no more heat left in the material. The sandy soil used is not of the right kind.

NAMES OF FRUITS: A. M. Grapes: Mrs. Pinco's Black Muscat.—J. H. W. Apples: Egg or White Paradise.—Kimbrell, Apple: Hambledon Deux-ans. The name you give, Old Denson, is evidently a corruption of Deux-ans (of the French).

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—C. K. *Cymbidium Mastersii*, also known as *Cyperorchis Mastersii*.—H. C. P. A very fine variety of *Cattleya labiata*, but scarcely worthy of a distinguishing name in view of the many fine varieties of it which have already appeared.—G. T. *Poinsettia pulcherrima* (the scarlet), and *Fittonia argyrea*.—*Constant Reader.* You could not do better than procure the work on Roses you name. The silvery-leaved hardy plant is *Stachys lanata*.—R. B. *Iris pseud-acorus*.—A. B. *Euonymus europæus* (Spindle-tree); 2, *Cedrus atlantica*, or Libani, we cannot tell which from the specimen; 3, *Abies nobilis*; 4, *Juniperus virginiana*; 5, *Cryptomeria japonica*;

6, *Abies Pinsapo*.—E. R. *Celtis occidentalis*, perhaps *Acer palmatum* var. Specimens inadequate, and badly packed.—H. G. *Cotoneaster frigidus*.

ROMAN HYACINTHS: *Market Study.* Like other Dutch bulbs for flowering early, they must be procured and potted as soon as they can be obtained, and they must then be kept in the dark till the soil is filled with their roots, and the crown of leaves containing the flower has pushed up some 2 inches or more. The bulbs may be grown thickly together in pots, jardinières, boxes, &c. To have them in flower early, it is necessary to put them into a warm house of 60° to 70°, on shelves near the light, first pushing them on in a hot-bed having a warmth of 75°, if you have it; but they do fairly well without this help. Do not stand them on the ground as you suggest, unless the ground is but a short distance from the glass, and no plants are grown overhead. Of course, if you are growing them wholesale for cutting for market, a little drawing of the flower stem is no disadvantage.

SICK BENEFIT SOCIETY: *Staley.* The United Horticultural Benefit and Provident Society undoubtedly offers a better investment to young gardeners than any such society you name. For reasons that have been frequently stated in these columns, we would strongly advise you, or any other young gardener, to choose the one special to the profession. Send an application for particulars to the Secretary, W. Collins, 9, Martindale Road, Balham, S.W.

SOUVENIR DE LA MALMAISON CARNATIONS: J. K. We must suppose that the cultivators of these varieties of the Carnation have nothing further to add to what has already appeared in the gardening journals. These Carnations do not seem to be "everybody's" plants; whilst the ordinary Tree, or perpetual Carnation, anyone with a cold pit or greenhouse can succeed in growing satisfactorily. Growers of "Malmaisons" please note.

SWEET PEAS: J. B. & Sons. It is to be expected that some varieties should be sterile. There is every degree of fertility among the variations, and you have unfortunately got hold of a sterile form. Next season try artificial fertilisation.

TENNIS LAWN: A. R. If it has not been mown since August, the grass will be long, and will require mowing with a scythe. In doing this, cut pretty close, rake off the mowings with a wooden rake, then sweep it with a half-worn-out broom; finally giving it a thorough rolling. It may need re-turfing in places that are worn, or sunk below the proper level. A dressing of sifted loam and stable-manure, or this kind of manure alone, may be used during the winter, raking off what has not sunk into the turf in March.—*Tennis Player.* If the grass has come up thinly, you might strew finely-sifted loam three-quarters, woodashes quarter, over the lawn during the winter so as to partially hide the grass. It is now rather late to sow grass seed; moreover, owing to the seed lying long before germinating, the seed-eating birds might devour a large proportion of them, and it will be better to wait till April before sowing the following grasses, *Poa trivialis*, *Alopecurus pratensis*, and *Festuca duriuscula*, together with a little (one-eighth of the whole bulk) of *Trifolium minus*. These seeds may be scratched in with a fine-toothed rake, or be very lightly covered with loam and woodashes. The clover (*Trifolium*) had better be sown first, evenly and thinly. It will die out in about three years, leaving a thick mat of grass. The frequent use of the roller is a matter of importance, and it is of great use in consolidating the surface, and causing the outward growth of the grasses. The extirpation of weeds and coarse grasses must receive attention from the first, and the scythe should be employed in preference to the mowing machine for the first two years.

VICTORIA MEDAL: B. Yos; we quite concur that the two horticulturists you name have as great, or greater, right to the honour than most of those who are included; but there is no getting over the numerical limitation. Should Her Majesty's life be prolonged for another ten years, then will be the time for the conferment of seventy additional medals! and then something may be done to remedy the defects of the present list. We cannot enter into personal details.

THE

Gardeners' Chronicle.

SATURDAY, DECEMBER 4, 1897.

CHARLES C. BABINGTON.*

It is not possible to do otherwise than receive with the greatest respect and sympathy a work dedicated by his widow in such touching terms to the memory of Professor Charles Cardale Babington. Anything like criticism seems out of place, and yet it is difficult to suppress a feeling of disappointment at the picture here presented to us. Professor Babington's name was not only a household word to successive generations of British botanists, but he was a resident in Cambridge for nearly seventy years, and a University Professor for more than thirty. During that time how vast and far-reaching has been the progress and the change in scientific thought, how great the difference in Cambridge itself! We find in the pages of the volume before us but faint indications of changes so great as to be almost revolutionary.

What we have is a sympathetic memoir of a patient, thoughtful, accurate, fair-minded, eminently religious man, deservedly beloved by those who were brought into personal contact with him. With strong convictions, he was yet averse from controversy; with a well-defined religious creed, he was yet not only tolerant, but, as far as possible, sympathetic with others who held different views. Our disappointment, if we can call it such, resides in the fact that in the present volume we find so feeble an echo of scientific and University progress—matters in which Babington could have had no mean share. We hear indeed of them, but, as it were, at a distance, and we learn but little of the part that Babington himself took in them.

The book opens with a well-written memoir by Professor Mayor, followed by a series of "Reminiscences" from personal friends, but few from botanists (excepting one from Mr. Britten) competent to give a general view of his botanical work, and yet no one exercised a greater influence in his own sphere than did Babington. His work in bringing the descriptive history of British plants in a line with that of the European Continent was an important step in advance. His careful and conscientious study of Brambles from 1846 to the end of his career, revealed an amount of variation which if not unsuspected was not previously fully

realised. There seem to be so many intermediate forms that it is hopeless to expect agreement as to their identity and nomenclature among students of the genus. A similar remark applies to the Hawkweeds, and to the Water-buttermugs, also favourite objects of Babington's study. The Professor himself was very cautious in drawing any inferences or inductions from the enormous mass of observations made by him in the field, in the herbarium, or in the garden, for a quarter of the Botanic garden was devoted to the cultivation of species of Bramble! Babington's tendency was to consider as of specific rank forms which others, belonging to a different school, treated as mere variations, not yet sufficiently fixed to warrant them being estimated as species. Thus, to give one illustration only, whilst Babington considered *Cuscuta trifolii* to be a species, Hooker does not even think it worthy of sub-specific rank, but makes it a variety of *C. epithymum*.

It is of very little consequence whether Professor A. considers a particular form as a "species," while Professor B. looks on it as a "variety." What is of consequence is, to ascertain the precise differences [that exist, to endeavour to find out the reason for those differences, their significance, and the precise relation they bear to other forms. Professor Babington's works, and his collections at Cambridge, though he himself paid relatively little attention to such matters, will be of great value to naturalists in search of evidence, and desirous of estimating its relative importance.

Reverting to the work before us, we find after the Reminiscences a reprint of his Journal from 1817, or thereabouts, to 1891. Babington's life was not a very eventful one, and a large proportion of the extracts might have been omitted, as adding nothing to the portraiture of the man, nothing to the history of botany, and as of no interest to the botanist or to the general reader. Of what use is it to print such entries (of which there are many) as "October 6, Cambridge;" "December 18, Cambridge;" "January 19, Linnean," &c. One entry we have found may interest our readers. It bears date July 6, 1847, the period when Prince Albert, as he then was, was installed as Chancellor of the University:—

"Horticultural show in Downing grounds. Went there at 11 A.M. to judge the 'specimen-plants in pots.' A great crowd of people in the afternoon. Between 9000 and 10,000 tickets sold, and many people got in without, either over the fences or through the gates, which were forced open by the press, and obliged to remain so for some time. The Queen went there. We dined together in the tent after it was all over."

Following the Journal, come extracts from his botanical correspondence, dating from 1834 to 1894, to which the same remarks apply as to the Journal, but to a much less degree. The letters, indeed, afford ample evidence of his patience and willingness to give assistance, and will be read by botanists with great interest as they contain so many notes on critical plants. The work is carefully printed, has an excellent index, and an admirable portrait, so that it will form an acceptable memorial to the friends of the late Professor, and an interesting record to the historian of British botany.

NEW OR NOTEWORTHY PLANTS.

PASSIFLORA PRUINOSA, Mast, sp. n.*

THIS is a beautiful and distinct Passion-flower (see fig. 117, p. 401), lately discovered by Mr. Im Thurn, and introduced from British Guiana by Messrs. Sander & Co. The leaves are glabrous, palmately three-lobed, subpeltate, green above, glaucous beneath, with the veins of a violet colour; the petioles are long, and provided with four to six cup-shaped glands. The stipules are a remarkable feature of the plant, being very large (2 inches long, $\frac{3}{4}$ inch wide), leafy, cordate, obliquely-oblong. The flowers are solitary on long axillary stalks, with three leafy oblong bracts near the top. The flower measures about 3 inches across when fully expanded; the tube short, fleshy, lobed, intruded at the base. Sepals oblong obtuse, aristate, glaucous-green externally, pearly within; petals rather shorter than the sepals, pale violet. Fauxial corona of very numerous threads, the outermost rows almost as long as the petals; deep violet at the base, in the centre yellowish, and curly at the apex; the succeeding rows are about half the length, thread-like, capitate, whitish or yellowish; median corona white, membranous, at first bent downwards, afterwards turning upwards and dividing into numerous erect threads, each hooked at the base. The other parts of the corona are relatively inconspicuous, and being described in the foot note, need not be further mentioned here.

The species belongs to the *Granadilla* section, the section which includes the greatest number of showy species, and among the *Granadillas* it may be relegated to a small subsection, in which the membranous or median corona is deflexed, and afterwards assurgent. In the size of the stipules it somewhat resembles the figure of *P. stipulata*, Aublet, but the form of the stipule, and especially of the leaf, is quite different. *Maxwell T. Masters.*

MILTONIA BINOTI, Cogn., n. sp.†

A plant recalling some forms of *M. candida*, the pseudo-bulbs, the leaves, the size and form of the flowers are nearly identical with those of the latter plant. The sepal and petals are cinnamon-brown, with the apex, a narrow margin, and one or two imperfect transverse bars of pale greenish-yellow. The lip, scarcely shorter than the lateral sepals, is broadly obovate, bright violet-purple veined with darker

* *Passiflora pruinosa*, Mast, sp. n., (f. *Granadilla Deflexa*).—Fruticosa scandens; ramis herbaceis teretibus fistulosis glabris rubro-lineatis; foliis remotis, petiolis 10–12 cent. long., teretibus glandulis cupulatis 4–6 dissitis munitis; stipulis 5 cent. long., 2 cent. lat., foliaceis oblique cordatis falcato-oblongis margine parum glandulosis, laminis 18 cent. long., 23 cent. lat., foliaceis, superne laete viridibus subtus glaucis, nervis violaceis, subpeltatis basi rotundatis ad medium trilobatis, sinubus latis, lobis divergentibus oblongo-lanceolatis, margine parum glandulosis, lobo medio longiore; pedunculo axillari 1 floro; bracteis flori approximatis verticillatis foliaceis cordato-oblongis; floribus diametro 8 cent., tube brevi ventricoso longitudinaliter sulcato basi intruso; sepalis herbaceis circa 4 cent. long., oblongis cucullatis aristatis dorso viridibus intus lacteis; petalis parum brevioribus pallide lilacinis; corona faucialis pluriseriali filamentosa, filis extimis petala subaequantibus basi intense violaceis ad apices capillares curvatis albidis flavescens, filis intimis numerosissimis exterioribus dimidio brevioribus lilaceis capitatis albidis; corona media basi tubulata membranacea albidis deflexa dein assurgente et in filis ascendens basi unctis dividente; corona infra mediana carnosula annulari deflexa angusta; corona basilaris membranacea cupuliformi gynophori basin cingente; gynophoro tereti glabro maculato; ovario oblongo glauco, stylis clavatis; fructu—seminibus oblongis obtusis.

Guian. Brit. Im Thurn.

† *Miltonia Binoti*, Cogn.—Pseudobulbis elongato-oblongis, valde compressis, levibus, apice diphylis; foliis elongatis, lineariliguatis, acutis, basi constrictis, laete viridibus; pedunculo communi erecto gracili, teretisculo, plurifloro, foliis brevioribus; bracteis linearilanceolatis, acuminatis, pedicellis brevioribus; floribus 7 cm. latis; sepalis petalisque aequilimis, p-tulis, anguste bilongis acuminatis, margine leviter undulatis; labello sepalis lateralibus vix brevioribus, p-tulo, usque ad basin libero, satis concavo sed non convulso, late obovato, apice rotundato-subtruncato et apiculato, margine lateraliter undulato et obscure 2–3-lobato, disco inferne 5-ristato, cristis medianis exterioribusque brevioribus; columna longiuscula, recta, subsemi-cylindrica, alis angustis, margine undulato-denticulatis, apice acuminatis; clinandrio margine angustissimo non membranaceo crescit in Brachia.

* *Memoria, Journal, and Botanical Correspondence of Charles Cardale Babington*, . . . (Cambridge: Macmillan & Bowd.)

lines, not curling like a horn round the column as in *M. candida*, but merely rather concave. The column, a centimetre long, is whitish tinged with lilac, the wings are narrow, the edges undulate-denticulate, ending at the top in a stout triangular acuminate tooth; the edges of the clinandrium are very narrow, and not furnished with a wide membranous border such as is the continuation of the anterior wings in *M. candida*.

It may be seen from these characteristics how *M. Binoti* principally differs from *M. candida* in the lip and the column, which organs much resemble, on the contrary, those of *M. Regnelli*, and especially those of its variety *purpurea*. We are disposed to consider this as a natural hybrid between those two species. *M. Binoti* was sent from Brazil by M. Binot, of Petropolis, to M. A. A. Peeters, of St. Gilles, Brussels, and at the request of the latter we have named it after the introducer. M. Peeters tells us that the first plant flowered November 21 last. *A. Cogniaux*.

VANDA CERULEA VAR. *PEETERSIANA*, *Cogn. n. var.*

This fine variety, remarkable for the complete absence of blue in the flowers, was shown in an importation from the Khasia Mountains, in November, 1896, by M. A. A. Peeters, horticulturist, of St. Gilles, Brussels. These are the characteristics of the plant:—Flowers very large, sepals and petals very pale lilacy-rose, rather brighter at the edges, and particularly towards the tip; lip rose, rather bright lilac towards the tip, shading insensibly to white towards the base, which is pure white, as is the spur, with a small spot of orange-yellow at the base of the disc; column white. The specimen which M. Peeters bloomed last November bore nine flowers. *A. Cogniaux*.

DENDROBIUM BARBATUM, *Cogn. n. sp.**

This species, which seems to us to be allied to *D. ciliatum*, comes from Upper Burma, where it grows in company with *D. Brymerianum*. It was introduced by M. De Lairese, a Liège grower, with whom it bloomed last June.

The stem, a rather yellowish green, is about 1 dec. high; it bears six or seven lanceolate linear, clear green leaves about two inches long. Racemes terminal, short, bearing four or five flowers almost wholly pure white. Sepals about a centimetre long, the lateral ones rather larger and lightly tinged with rose at the tip, while the rather long and obtuse mentum is yellowish-green. Petals erect, narrow; lip erect, trilobed, with very obtuse lobes, edged with long flexuous hairs; intermediary lobe larger than the others, yellow; the rest white. A few specimens of this species were introduced; one of them is in Sir Trevor Lawrence's collection, another was offered by M. De Lairese to the Royal Gardens, Kew. *A. Cogniaux*.

AUTUMN FLOWERS.

PLUMBAGO LARPENTE.—This little Chinese plant blooms so late in the season out-of-doors that it often fails to open its flowers unless the position of the bed is warm and sheltered, precautions especially necessary in the Midlands and the North. It is not a showy plant when observed at a distance, but a close inspection discloses flowers of a beautiful Gentian-like-blue colour, which is very pleasing; and the foliage and stems are also prettily tinted with red.

* *Dendrobium barbatum*, *Cogn. (Sect. Stachyobium)*.—Caulibus brevibus, profunde sulcatis, inferne satis gracilibus vaginis 2-3 vestitis, superne incrassatis plurifoliatis; foliis distichis, subcoriaceis, lineari-lanceolatis, acutis, basi breviter vaginatis; racemo subterminali, nutante, paucifloro, foliis brevioribus; bracteis membranaceis, anguste ovatis, obtusis, trinerviis, pedicellis paulo brevioribus; floribus satis parvis, submembranaceis, breviuscule pedicellatis; sepalis dorsali late lanceolato, acuto, inferne erecto, superne reflexo; sepalis lateraliibus paulo majoribus, triangulari-lanceolatis, acuminatis, erectis apice leviter recurvis; petalis erectis, lanceolato-rhomboides, acutiusculis, sepalis dorsali aequilongis; mento longiusculo, oblongo, obtuso; labello erecto, sepalis lateraliibus aequilongo, ambitu obovato-cuneato, distincte trilobato, lobis ovato-rotundatis, margine integerrimis et pilis elongatis flexuosis densiuscule ciliatis marginatisque, lobo terminali paulo majore intus puberulo, disco puberulo tenuiter biocostato; columna brevi, obtuse bidentata. Crescit in Birmania.

It may easily be increased by division of the root-stock in the spring; and as it does not grow more than 1½ foot in height, and has small flowers, it should not be placed more than 3 feet from the edge of the path.

Sternbergia lutea.—This pretty little Amaryllid is a native of Central and Southern Europe, and has been considered by some to be the "Lily of the field" spoken of in the Scriptures. Others suppose a species of *Anemone* to be the plant so designated, and, certainly, these are more "gloriously arrayed." The *Sternbergia* is perfectly hardy as far north as this, but it requires a warm position in order to flower it well, such an one as the front of a forcing-house, or border facing south, with a background of evergreens, suits it, and in such positions it throws up its yellow Crocus-like flowers at the end of October, and in November. Although by no means a plant that makes a striking mass of colour, it is very interesting to see its clear yellow flowers nestling among the green leaves when other out-door flowers are scarce, and it is often mistaken for a species of *Crocus*.

Phlox amena.—Although this plant makes its finest display in May, it also affords a number of blooms in late autumn; and at the present time, November 6, it is the gayest of all the outside flowers, commanding attention at once when seen in a mass. The present season is favourable to it, for the reason that severe frost has not occurred. It forms a useful permanent edging to beds and borders as one that is easily kept within bounds, and the leaves grow closely together. The best season at which to propagate the plant is the middle of the month of May, when it ceases to flower. The plants, or a sufficient number of them, should be dug up and pulled into small pieces, which soon make good plants if planted firmly, and afforded water until growth commences. It seldom exceeds 6 inches in height, and the blooms are of a pleasing rosy-pink colour. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

KEW NOTES.

RUBUS BIFLORUS.—For producing an autumn and winter effect there is nothing of its kind more striking than this *Rubus*. Several of the Brambles are noted for their white, or blue-white, bark in winter. *R. leucodermis*, *neglectus*, and *lasiostylus*, are among the number, but none of them, so far as my experience goes, equals this Himalayan *R. biflorus*. It is not inferior even to the beautiful Willows, *Salix daphnoides*, and its variety, *acutifolia*, which make so fine a feature in the Knap Hill Nursery every winter. There is a group of plants near the Flagstaff at Kew, which anyone interested in winter effects of vegetation, and to whom this *Rubus* is not known, ought to see. The thicket of white stems, 6 feet or 8 feet high, is conspicuous at a great distance, and even on dull days, but this afternoon (November 29) I happened to see the group with the low, almost level rays of the sun lighting up the stems, and this added greatly to the effect. Away from the smoke and black fogs of big towns it would doubtless show to greater advantage than it does near London, but here it is especially valuable because it thrives better than any of these white-barked shrubs. Owing probably to climatic disadvantages, the two Willows mentioned above, for instance, never at Kew put on the beautiful glaucous covering one sees in the country. The *Rubus* is a vigorous, quick-growing shrub, and should be planted in rich, loamy soil. The Kew plants are about three years old, and were raised from seed, which ripens occasionally during our hottest summers.

THE GOLDEN OSIER (*SALIX VITELLINA*).

There is not so much, perhaps, made of hardy shrubs with brightly-coloured bark as might be, yet if all of them were brought together, they would make quite a respectable list, and it is upon such plants to a very great extent that we have to depend for colour out-of-doors during midwinter. I have already in a previous note mentioned several of those with white stems, and among those of a different colour it may be worth while to draw attention to

this Willow, for although a native of our own country its beauty in winter and spring, when given special cultivation, is either not known or is not sufficiently made use of. It belongs to Borreri's section *Alba* of the genus *Salix*, and is, indeed, so nearly allied to *S. alba* that some authorities make it a variety of that species. At Kew it is represented by two forms, one with yellow, the other with red bark. Both are grown on the island of the Lake together in mixed groups, and from now onwards till spring they give one of the brightest of outdoor effects. During sunshine especially they attract the eye, for, growing on the edge of the water, their beauty is doubled by reflection. In order to show this Willow at its best, it is necessary that it should be cut hard back each spring. If let alone it will eventually grow into a tree 30 feet or more high, but it is not short twiggy shoots that are wanted, for as a garden plant its full beauty can only be brought out by making it produce each year a crowd of long thick wands. This is done by giving it a moist place, a fairly rich soil, and by pruning back the previous season's shoots to a few buds every February or March. *W. J. B.*

FLORISTS' FLOWERS.

CHRYSANTHEMUMS.

I DO not ever recollect so fine a display of bloom in the open air in November as we are enjoying at the present time. The air in this part of the country has been dry and warm, with much of bright sunshine, which accounts for the wealth of bloom to be seen here, and in almost every cottager's garden as well. Plants grown in pots for furnishing large blooms require great attention, but where large quantities of cut-flowers are looked for, a large number of *Chrysanthemums* should be planted on a well-prepared piece of ground, and made very firm. If planted out at the end of April or early in May, with very little after care, these plants will lift well after the buds are set. We have had a very fine lot, and it is needless to remark have found them very useful for cutting from. Several of these were cut down to within 3 to 6 inches of the ground-level in the middle of the month of June, others stopped once at the end of the month of May; all of which have done well, although the flowers are not so large as those grown on plants in pots. The flowers are more useful when removed with long stems. I have found the following varieties good to plant out: Stanstead White (one of the best), Major Bonaffon, Lady E. Saunders, Elaine, Mrs. G. Rundle, Mrs. Dixon, William Seward, and Mrs. G. Gleany. Before lifting the plants at the end of September, or later if the season is mild, the roots should be thoroughly moistened some hours previously with water; dig up the plants carefully, and have the pots prepared, potting them where they are lifted, and carrying them to some shaded spot, keeping them from flagging by frequent overhead syringings, with plenty of water to the roots, &c. They should be staked just sufficiently to keep the shoots from breaking. *H. Markham, Northdown, Margate.*

SOUVENIR DE LA MALMAISON CARNATION.

From the frequent inquiries observed in the *Gardeners' Chronicle*, it is apparent that there are cultivators of this plant who do not meet with success. The worst foe to the plant is the fungus named *Helminthosporium echinulatum*, whose presence in the leaves is not suspected till spots occur on the outside, when it is always too late to use remedies. The cultivator is in no wise to blame for this state of things—that is to say, cultivators of experience and intelligence; for it is the experience of many that they have cultivated these plants to perfection in one locality, and failed utterly in another. And provided the plants are not over-fed, or kept too warm or close, there is little for which the cultivator can reasonably be blamed. If enquiry were made of those who still grow the plants successfully, it would be found quite a simple method

differing culturally but little from that given in other gardens where failures are the order of the day. Good fibrous loam three-fourths, and equally good fibrous peat one-fourth, should form the chief part of the compost in which the varieties of this *Dianthus* are to grow. Plenty of sharp sand, some burnt clay, a shovelful of bone-meal, and twice as much charcoal of horse-bean size, should be added to each barrowful of soil; no manure—that is to say, not any of the usually prescribed "Mushroom-bed manure" that appears, perhaps too freely, to find its way into most mixtures of soils. The plant is a gross grower naturally, and the aim should be, so far as this

situated in low-lying districts, or are near a large river or other considerable body of water. Along the Thames valley I could give the names of a dozen growers in a large way who, after a year or two of trying and failing, threw their stock of plants to the rubbish-fire. These men were not cultivating a few plants, but some of them had several thousands, and the leading varieties, which half-a-dozen years ago fetched good prices. Some of my neighbours, who formerly had house after house 100 feet long by 21 feet wide filled with these plants, were compelled to clear out the entire stock. In my own case, some 3000 plants went the same way, after all the trouble

within the cuticle of the leaf from vegetating at the proper time, but so far as I can at present determine, it arrests and destroys its vitality. One rather badly affected plant on which I experimented, using the sulphur with a small camel-hair pencil, and collecting all I possibly could of the spores, I cleansed the pencil in sulphured water. By careful watching, I was able to drop some sulphur on the spot, which prior to bursting is of an ash-grey tint, and in this way the spores were more or less ruined. I note also that the spores on dressed plants are of a different brown tone to those on undressed plants, and I have hope that this is a sign of diminished vitality.

FIG. 115.—VIEW OF IVY ARCH, AND, CURIOUSLY-PRUNED IRISH YEWS, IN SIR C. ISHAM'S GARDEN, LAMPORT HALL.

(The "Eagle" Walk is 340 yards long, and by its borders there are 106 specimens of Irish Yew, all pruned differently. They were described in our issue for Sept. 25, p. 209.)

is likely to be controlled by soils and such like, on the side of imparting solidity to the tissues rather than the reverse, and preserving intact the waxy bloom on the grass, which in itself is a protection against the inroads of fungi and insects. Potting should be done firmly, light loams being rammed, and water should be not abundantly afforded. A cool and well-ventilated house affords a suitable place for them. A perfect drainage is an essential condition of success. In gardens where the plant is grown well, it is an easy matter to make them susceptible to disease by a little careless treatment—as for instance, frequent repotting, and over-large pots. The growers who mostly fail entirely are those whose gardens are

of layering, potting, &c. To attempt any cure by picking off the affected parts not only skeletonises the plants, but is in effect as disastrous as the disease, no root-action going on without leaves.

Nor is it only *Souvenir de la Malmaison* Carnation that is affected by this fungus, it being abundant on *Tree* or *Perpetual* Carnations, *Mdlle. Carle*, *Winter Cheer*, &c. Others, again, of the small-leaved kinds, such as *Miss Joliffe*, the fungus does not affect. Although I have long since dispensed with *Malmaisons*, I have the fungus still, and this year I have been trying to annihilate it by syringing the Carnations with a solution of sulphur mixed with soft-soap. This, of course, does not prevent the fungus already

It is very curious to note the districts where this pest is most felt. Invariably all low-lying places are much the worst. In some districts the affected plants become free, and to some extent at least I believe this is so around Chelsea, owing to the atmosphere being charged with noxious sulphurous from the gas works there.

Usually in hilly districts there is perfect immunity from attacks of the fungus, and the plants with ordinary care are quite a success. Perhaps the most perplexing thing is the inability to grapple with the pest. So far as I know, preventive dressings with the above-named mixture is the only means even of minimising an attack. J.

THE BOTANICAL HISTORY OF THE UVA, PAMPAS GRASS AND THEIR ALLIES.

(Concluded from p. 378.)

CORTADERIA.—The species constituting this genus are closely allied, and their distinction is consequently difficult. This difficulty is, moreover, increased by the circumstance that the spikelets are more or less, though slightly, heteromorphic, according to the sex, and that it is not always possible to ascertain beyond doubt from herbarium specimens whether two specimens representing different sexes actually belong to the same species. Besides, the *Cortaderias* being tall, long-leaved grasses, and rather unwieldy for herbarium specimens, the number of individuals found in the collections is neither great, nor are they always complete, and selected so that they fairly represent the average type of the species. Here the aid of field observation, and of notes made on the spot, is very much desired. I have seen only *Cortaderia argentea* alive (in cultivation). The descriptions of the other species are exclusively based on the specimens in the herbarium at Kew, and in that of the Natural History Museum in London, and on fragments of panicles from the herbarium in Berlin, which Professor Engler and Professor Urban were good enough to communicate to me.

SYNOPSIS OF THE GENUS CORTADERIA.

Cortaderia, Stapf.—Spikelets dioecious, loosely 3- to 7-flowered, rhachilla glabrous, disarticulating above the glumes and between the valves, apex tabescent. Glumes hyaline, very narrow, 1-nerved, sub-equal. Valves sub-hyaline or hyaline, lanceolate or ovate at the base, acuminate, 3-nerved, awnless, mucronate or finely aristulate, glabrous or scantily hairy in the δ , copiously hairy towards the base in the σ , callus slender, hairy. Pales 3 to 6 times shorter than the valves, hyaline, 2-keeled, minutely 2-toothed or obtuse. Lodicules nerved, ciliate. Stamens 3 in the δ , reduced to as many minute staminodes in the σ . Ovary glabrous, rudimentary in the δ ; styles short, distinct; stigmas slender, plumose, laterally exerted. Grain narrow, oblong, embraced by its valve and pale, free, sub-terete, or slightly compressed from the back; hilum linear, equalling about one-half of the grain; embryo shorter than the hilum. Perennial grasses, forming large tussocks; rhizome very short; shoots intravaginal; culms biennial, simple. Leaves mainly crowded at the base, sheaths increasing in length from the base to the top, imbricate; ligules reduced to a dense line of silky hairs; blades very narrow, caudate-attenuated, very long and flexible. Panicle ample, dense, or rather loose, shining or plumose.

Species 5:—South America, almost confined to the extra-tropical region, and the Andes as far as Ecuador.

Glumes 6 to 8½ lines long, very narrow, linear, produced into a very long and fine acuminate; valves 6 to 8 lines long, lanceolate, long acuminate.

Panicle subsecund, 1 to 2 feet by 4 to 6 inches (lowest branches to 9 inches), rather distinct in the δ and σ ; valves of δ glabrous, or almost so; middle nerve scarcely excurrent; hairs 3 to 4 lines long. 1. *argentea*

Panicle symmetrically oblong, ½ to 1½ foot by 2 to 2½ inches (lowest branches to 5 inches), almost alike in the δ and σ ; valves of δ hairy, middle nerve excurrent into a bristle 3 to 5 lines long; hairs 2 lines long. 2. *aracana*

Glumes 4 to 5 lines long, narrowly lanceolate to linear-lanceolate, acuminate, tips usually minutely truncate or two-toothed; valves 4 to 6 lines, lanceolate or ovate-lanceolate, acuminate.

Panicle very dense; glumes 4 to 4½ lines long; valves 4 to 5 lines long.

Panicle rather stiff, 1 to 1½ foot long by 2 to 2½ inches, symmetrically oblong, very softly silky, shining; valve-tips very fine, often shortly aristulate; staminodes with slender filaments ½ to 1 line long. 3. *speciosa*

Panicle more or less nodding or secund, often lobed, 1½ to 1½ foot by 4 to 5 inches, coarsely silky, scarcely shining; valves caudate-acuminate, tips rather rigid, curved, staminodes ½ line long. 4. *rudiuscula*

Panicle rather lax, 1 to 2 feet by 3 to 6 inches, lowest branches to 1½ foot long; branchlets very slender; glumes and valves very delicate, 5 to 5½ lines and 6 lines long respectively; filaments of staminodes very slender, often with clavate tips, to ½ line long. 5. *Quila*

1. *Cortaderia argentea*, Stapf, "the Pampas-grass of gardens."—Flowering culms, 6 to 8 feet high (excl. panicle), elongated internodes (i.e., those which are longer than 1 inch), about ten to twelve, the uppermost (peduncle) 2' to 2½ feet long, the preceding 4 or 5 to 10 inches long. Upper sheaths to 2 feet long; blades 6 feet by 3 to 5 lines. Panicles broadly-oblong, 1 to 2 feet by 4 to 6 inches, the lowest branches to 9 inches long, often with a purple, rarely with a greenish-brown tinge; those of the δ laxer, with the branches more

nodding, and more or less secund, silvery; of the σ silky, feathery. Spikelets 3 to 6-flowered 5 lines long; glumes very narrow, linear, produced into a very long and fine acuminate, the lower about 6 lines by ½ line, the upper 6 to 8 lines by ½ line; valves lanceolate, long acuminate, 6 to 8 lines long, of the δ glabrous, or very scantily hairy; of the σ densely hairy; hairs 3 to 4 lines, middle nerve scarcely excurrent. Stamens very minute, cylindric or linear, ½ to ½ line long, with hardly any trace of an anther; grain 1 line. *Arundo dioca*, Spreng., *Syst.*, i. 36 (non Lour.); A. Selloana, Schult., *Mont.*, 605. *Gynierium argenteum*, Nees, *Agrost. Bras.*, 462; G. diocum, Dallière, *Pl. Ornam.*, i. t. 42; G. purpureum, Carr., in *Rev. Hort.*, xxxvii, 419.

Distrib.—Brazil, Rio Grande do Sul, without locality, δ Fox; very common in the Campos of Alegrete, σ Glaziou, 11,635. Paraguay, Rio Pilcomayo, σ , Morong, 950. Uruguay, without locality, δ , Gilbert, "plentiful in all parts of Banda oriental; σ , Tweedie; Montevideo, δ , Sellow. Argentine, "Marshes of La Plata," σ , Tweedie; Buenos Ayres, δ , Tweedie; southern parts of the State, to the south of Laguna Quentre, and Fuerte Lavalle, σ , Lorentz. Bahia Blanca, σ , Claraz, 23; σ , Tweedie.

I have confined myself to the enumeration of those specimens which I have actually examined. According to this list of localities, the area of *C. argentea*, the Pampas-grass, extends from Southern Brazil to Northern Patagonia, and it nowhere crosses the Andes. Doell records it also from Minas Geraes, Rio Janeiro, and S. Paul; but as Peckolt states that the grass is grown as an ornamental plant in gardens in Brazil, the spontaneity of the specimen referred to by Doell is somewhat doubtful—at least, so far as the environs of Rio Janeiro are concerned.* There are frequent references to *C. argentea* in various papers dealing with the vegetation of the Argentine and Chile; and it is indicated for Chile by Gay in his *Flora Chilensis*, and for the western provinces of the Argentine (Catamarca and Salta) by Grisebach, in his *Symbola Florae Argentinae*. These statements may, however, partly be proved to be erroneous, on the evidence of the specimens quoted; whilst in other cases, where there is no material for examination forthcoming, they must be taken at present as yet unverified, and as being in contradiction to what we actually know; and it is most likely that in those cases a confusion of *C. argentea* with *C. rudiuscula* and perhaps with *C. speciosa* has taken place.

A few words concerning the popular name of *C. argentea*, namely, "Pampas-grass," may be in place. The name appears, I believe, for the first time in Paxton's *Flower Garden*, i. (1850—51), p. 175, where the plant is first mentioned also as a new introduction into horticulture, the merit for which is due to Mr. Moore, of Glasnevin, Dublin. [A figure and a description from D. Dalkeith appeared in our issue for November 29, 1851.] There is, however, no reason given for this name, or the origin of the name, but a few years later we read in the *Gardeners' Chronicle*, 1854, p. 708, "We are unable to say with certainty where the species grows wild. The Prussian botanist, Sello, is reported by Nees v. Esenbeck to have found it at Monte Video, and we know that vast tracts (pampas) near that city, and in all the adjoining countries, are covered with what is familiarly called "Pampas Grass," but we have no certainty that the name is applied to one large grass only, and that our *Gynierium* is that one." Now, however, common *C. argentea* may be in certain localities, all the evidence tends to show that it is confined to the neighbourhood of watercourses, and to depressions where there is a constant and sufficient supply of underground-water, and that it is absent from the greatest part of those vast grassy plains which we generally call "Pampas." The grasses which form so prominent a part of the pampas vegetation, belong rather to very different genera. Niederlein, a good authority on the Argentine vegetation, says, indeed, that the occurrence of *C. argentea* in the pampas, is by no means so general as to justify

* After the manuscript had gone to press, I received, through the kindness of M. Crépin and M. Durand, a branch of the specimen quoted by Doell as having been collected near Caldas, in the state of Minas Geraes. It was taken from a δ panicle of *C. argentea*. Caldas is situated in the extreme south-west of Minas Geraes, within the basin of the Paraná, and in the dry region of the campos. Thus, it seems that *C. argentea* extends along the Paraná and its tributaries into the southern parts of tropical Brazil. On the other hand, I have received, through Professor Urban, a communication from M. Glaziou, according to which this species occurs in Rio Janeiro only in the cultivated state.

the name "Pampas-grass," and the less so as the *Cortaderia* is much more common in the Andes, ascending there to high altitudes.

2. *C. aracana*, Stapf.—Culms rather slender and short, elongated internodes few, the uppermost over 1 foot long. Blades to 4 feet by 3 lines. Panicles oblong, erect, very dense, ½ to 1½ foot by 2 to 2½ lines, the lowest branches to 5 inches long; straw to light bronze coloured, lustrous, those of the σ more silky, otherwise like the δ . Spikelets four- to seven-flowered, to 10 lines (exclusive awns), glumes very narrow, linear, produced into a very fine and long acuminate, the lower 7 to 8 lines by ½ line, the upper 8 to 8½ lines by ½ line; valves lanceolate, long acuminate, 7 to 8 lines, hairy in both sexes, but more in the σ , hairs 2 lines, middle-nerve excurrent into a bristle 3 to 5 lines long, staminodes with short thick filaments, about ½ line long, and minute rudimentary anthers.

Distr., Chile, Valdivia, σ Lechler, 613; σ Philippi; Chiloe, δ , King.

A very fine species with rather narrow, dense, and exquisitely lustrous panicles.

3. *C. speciosa*, Stapf.—Flowering culms rather stout, uppermost internode over 1½ foot long. Blades over 1½ foot by 3½ lines. Panicles oblong, very dense, or the δ laxer, strict, 1 to 1½ foot by 2 to 2½ inches, elegantly lustrous and silky. Spikelets three- to four-flowered, to 5 lines long; glumes very narrow, linear-lanceolate, acuminate, subequal, of the δ 4½ to 5½ lines, of the σ 4 to 4½ lines, by ½ line; tips minutely two-toothed; valves lanceolate in the σ , from an ovate base setaceous acuminate, in the δ 5 to 6½ lines, in the σ 4 to 5 lines long, and silky, hairs 2 to 2½ lines long; staminodes, with very fine filaments to ½ line long, and minute but distinct rudimentary anthers; grain ½ line. *Gynierium speciosum*, Nees, in *Meyen, Reise*, i., 407 (nomen), and in *Nor. Act. Nat. Cur.*, xix., Suppl. i. (1843), 153.

Distr., Chile, without locality, Gay; Bio Bio, Antuco, δ , Poeppig; Santiago, Rancagua, σ , Bertero. Valparaíso, Cuming, σ , 386; seaside swamps near Concepcion, σ , Poeppig; Copiapó River, σ , Meyen. Atacama, Borchers and Philippi.

4. *C. rudiuscula*, Stapf.—Smaller and more slender than *C. argentea*. Culms with few elongated internodes, the uppermost to 2 feet long; blades to 4 feet long, and to 6 lines broad; panicles oblong, more or less nodding, very dense, often slightly lobed, 1½ to 1½ foot by 4 to 5 inches, the lowest branches to 9 inches long, those of the δ somewhat laxer, scarcely shining, of the σ rather coarsely silky. Spikelets three- to five-flowered, 5 to 7 lines long; glumes very narrow, lanceolate, sub-equal, 4 to 4½ lines long by ½ to ½ line; tips nearly always minutely 2-toothed, valves lanceolate from an ovate base, rigidly caudate-acuminate, about 4 lines long, minutely mucronate, scantily and shortly hairy in the δ , copiously hairy in the σ , hairs 3 to 4 lines, spreading, rather stiff; staminodes very small, filaments thick, ½ to ½ lines, rudimentary anthers hardly distinct.

Distr.—Argentine, Tucuman, Serra Aconquija, 8300 feet, δ , σ , Lorentz and Hieronymus, 732; Salta, Nevado del Castillo, σ , Lorentz and Hieronymus, 78. Chile, Santiago σ , Philippi; Santa Rosa de los Andes σ , Hall.

Philippi's *Gynierium atacameum*, which I know only from the description, is perhaps referable to *C. rudiuscula*, and I suppose that this is also the case with the "*Gynierium argenteum*" of F. Kuntz, of which this author says that it is common along the watercourses of the Cordilleras of Mendoza, covering near the Rio Salado vast tracts of moorland, the so-called "Cortaderales," and ascending to high altitudes, where it is very much dwarfed.

5. *C. Quila*, Stapf.—Culms stout, uppermost internodes more than 1 foot long. Blades to 4 lines broad (I have not seen any intact blades from the lower leaves). Panicles large, oblong, rather lax, erect or slightly nodding, 1 to 2 feet long, the lower branches to 1½ foot long, very slender, erect, or flexuous and nodding, loosely ramulous, those of the δ very lustrous, of the σ silky. Spikelets 3 to 5-flowered, 5 to 7 lines long; glumes very narrow, linear-lanceolate, acuminate, acute or minutely 2-toothed, sub-equal, 5 to 5½ lines, by scarcely ½ line, nerve evanescent below the tip; valves lanceolate, long and finely acuminate in the δ , broader below in the σ , 6 lines long, glabrous or very scantily hairy in the δ , copiously hairy in the σ ; hairs 2 to 2½ lines, staminodes ½ line long, filaments very fine or clavate at the tips; rudimentary anthers very minute or hardly any. *C. Quila*, Nees, in *Nor. Act. Nat. Cur.*, xix., Suppl. i., 153. *Gynierium jubatum*, Lemoine ex Carr. in *Rev. Hort.*, xlix., 419. *G. roseum* Rendatleri, *The Garden*, viii., 165 (name only). [*Gynierium argenteum* carminatum Rendatleri, *Flora des Serres*, t. 2075; ex *Gard. Chron.*, Oct. 2, 1874, p. 419.]

Distr.—Bolivia, Condurpati, Cochipata, &c., near Sorata, in wet places amongst cliffs, 9000 to 12,500 feet, σ , Mandon, 1322; common in damp gullies on banks of streams about La Paz, σ , Pearce, σ , Rang, 26. Peru, Cuzco, 11,880 feet, σ , Pentland; Arequipa, σ , Meyen; near Lake Titicaca, σ , Meyen. Ecuador, Chimborazo, σ , δ , Roelz; Andes of Quito, in ravines, 10,000 feet, σ , Hall.

This species is common (according to M. André, in *Rev. Hort.*, 1886, 520) between 9000 and 11,000 feet on Imbabura, Guallabamba, Cotopaxi, Corazon, and Chimborazo.

The male spikelets are described from a cultivated plant, said to have been raised from seeds sent by Mr. Roelz. The glumes and valves are extremely delicate in this specimen, and suffused with the most delicate purple hue. This tinge is mainly due to the colouring of the nerves, and sometimes also of the callus. It occurs also in most of the female specimens, where the ripening grain is often deep purple. Specimens named *Gynierium roseum* Rendatleri in the Kew Herbarium are identical with Roelz's male examples of *C. Quila* σ Stapf, Kew.

PLANTS ON WALLS.

walls when left undisturbed often afford examples of the artistic effects produced by nature. Nothing is more beautiful than old walls covered with flowers growing from the

already spoken of the wall flower-beds of M. Edmond Boissier of Valleyres (Vaud), and of the number of species which he thus cultivates. The very rare *Saxifraga florulenta* has bloomed there for more than a quarter of a century, and the rarest *Campanulas* and *Androsaces* are quite at home.

why certain delicate Ferns, *Asplenium Seelosii* for instance, only grow in crevices of the rocks, and always perish in other situations. This is also why *Phyteuma comosum*, *Silene Elisabethae*, *Campanula Raineri*, *Eritrichium nanum*, *Androsace Charentieri*, *pubescens*, *glacialis*, *argentea*, *cylindrica*, *pyrenaica*, *helvetica*, and many other of these delicate plants which require sun, but which invariably die in our temperature, that is why I say again these plants succeed only under those conditions. They require no soil, not even sand, nothing but a little moss to hold them into the chink in the wall and keep them cool. This method of cultivation cannot be too strongly recommended for England for all plants which are considered difficult to grow in a damp climate. In the wall they have constant moisture tempered by the heat of the sun, and which cannot even soak the plants because they are in a horizontal position, and they cannot stagnate. Further, the absence of humus deleterious to xerophytic plants is certainly a great advantage. The plants find sufficient nourishment in the fissures of the wall in the water they absorb, and the air that they breathe. H. Correvon.

ASPHODELINE IMPERIALIS,

SIEHE, SP. N.

This is a splendid example of *Asphodeline*, taken at Thyana, Cappadocia. The flowers are large, of a reddish-white colour, the fruits of angular shape. The stem is furnished with leaf-scales, which are wanting in *A. Balansea*, *A. istmocarpa*, and *A. Dammeriana*. The magnificent rosette of leaves is somewhat prolonged up the stem, and not all of them springing from one base. The plant reaches a height of 8 feet, and is the largest of all the *Asphodelines*. The stem appears to be about to branch (ramify). As our illustration (fig. 116) shows, *Asphodeline imperialis* is an effective, strong-growing, herbaceous perennial. U. D., Berlin.

THE PROPAGATION OF ORCHIDS.

MANY consider it useless to attempt the propagation of Orchids in India, as they do not appear to be at all successful in growing them. The following notes will show that many Orchids can be successfully treated in this manner, even without the aid of a glass-house, but that great care must be taken of the plants.

Dendrobiums are easily increased by dividing the clumps, or, in some cases, cutting off the young growths that appear on the stems. When the clumps are divided, it should be seen that each piece thus treated has roots attached, and care must be taken that the roots are not injured when the knife is applied to the clump. When the clumps have been divided, the pieces should be placed in a cool shady situation, and very little water given until the roots appear to be increasing in length and strength. If it is desirable to propagate from the young growths on the stems, a little moss should be worked in among the roots of the growth, and more added, until the new growth has a good show of these roots; it may then be severed from the parent stem and potted.

The following Orchids may also be divided, and some can be increased considerably in this manner, viz., *Acanthophippium*, *Acineta*, *Acropera*, *Ada*, *Aeranthis*, *Anectochilus*, *Ansellia*, *Arundina*, *Bletia*, *Brassavola*, *Broughtonia*, *Calanthe*, *Catasetum*, *Cattleya*, *Cirrhopetalum*, *Coslogyne*, *Coryanthes*, *Cymbidium*, *Cypripedium*, *Epidendrum*, *Eulophia*, *Gongora*, *Goodyera*, *Habenaria*, *Laelia*, *Lycaste*, *Odontoglossum*, *Oncidium*, *Phaius*, *Stanhopea*, *Erides*, *Angraecum*, *Vanda*, *Saccolabium*, *Renanthera*, and *Phalaenopsis*, may be propagated by cutting off the top just below the first couple of roots, or by taking off the young growths from the base of the stock. *Phalaenopsis* often throw out young growths on the old flowering-stems.

Thunia stems can be cut up and laid on moss, occasionally watered, and young growths will appear in a short time.

and sides; these plants of rocks and walls often very lovely *Centranthus*, *Corydalis*, *Antirrhinums*, *Cheiranthus*, *Campanulas*, and so on. But besides its artistic side, rock has the advantage of protecting the most delicate plants, and enabling those species to develop which it is most difficult to succeed. I have

I allude here to a sustaining wall which supports a terrace, and which consequently is generally cool. But the stone itself is always cool, and in all cases the rock exercises a marvellous hygroscopic influence on the plants. It is a regulator, a controller, which absorbs moisture when abundant, and transmits it to the roots in proportion to their need of it. That is

FIG. 116.—ASPHODELINE IMPERIALIS: FLOWERS REDDISH-WHITE.

Arundina bambusæfolia stems, if cut into lengths of six inches and inserted in sand and leaf-mould, often commence growing nice little plants.

THE PRODUCTION OF BACK GROWTH.

In this manner some Orchids, that go on growing year after year and only produce one flowering stem, may be treated. Williams gives the following directions for this operation: "Take a plant that has back pseudo-bulbs, some four or five it may be, and cut the rhizome in two between the bulbs, not otherwise disturbing it, but allowing the bulbs to remain in the same place. The best time to cut these Orchids is during their season of rest, or just as they are beginning to grow. Any other Orchids that have pseudo-bulbs may be treated thus, but it must be remembered that no Orchid should be cut except when in vigorous health, and not then except to produce back growth. The resting season is the best for this operation, as when in vigorous growth they often produce two growths from the same pseudo-bulb, and continue doing so year after year, increasing rapidly in size, and forming excellent specimens. When this is the case, if it is required to increase the stock of a particular plant, take off a piece just as it is starting into growth; the plant taken off can be potted at once, and placed in shade, until it shows signs of growth, when bring it to the light. Often such growths are sold as original plants, even when in flower, and great care is necessary in looking after them." *"Canna," Indian Gardening.*

FORESTRY.

DEGREES OF THINNING.

ALTHOUGH thinning is an operation, concerning which no two individuals appear to entertain the same ideas, it is difficult to see why so much divergence of opinion exists on what after all is a very simple piece of business when once its principles are understood. In this country, the term "thinning" is applied to almost any operation which reduces the number of trees in a plantation without actually leaving the ground bare. The presence of a few dead branches is generally considered indicative of an unnatural condition of affairs which requires an increase of air and light to put it right; the idea being, of course, that each tree should have ample space for the development of its branches, and the rapid thickening of the bole resulting therefrom. It is unnecessary to state the various objections advanced against this arboricultural system of thinning, as a slight acquaintance with the literature of modern forestry render them familiar to anyone. But it is evident from the occasional expressions of opinion which appear in the *Gardeners' Chronicle* and elsewhere, that a great deal of misunderstanding exists over the definition of the term itself, as represented by its three degrees of light, moderate, and free thinning. The old-fashioned forester, who has usually been taught his business in a north country district, where Larch and Scots Fir form the chief bulk of the plantations, invariably sticks to the rule of keeping a space between his trees equal to one-third of their height, or as near that distance as possible. He religiously applies this rule to any and every species he may have to deal with, and does not hesitate to place any plantation not so thinned amongst the numerous instances of bad management, which result from the lack of a north country training. There are others again who go to the opposite extreme, and contend that any form of thinning is not only unnecessary, but positively detrimental to the production of good timber, and point, in support of their arguments, to the high quality of timber grown in natural forests which have never been thinned by artificial measures. Both of these opposing arguments have their weak points, although better results usually follow the adoption of the "no thinning" system than that of the free thinning principle of the old school. Let us endeavour to sum up the points for and against these two systems severally.

The chief objects in view in the management of most British plantations are, we may assume, profit and ornament. How does the freely-thinned plantation fulfil these objects? As regards profit, the advocates of this system usually contend that the trees in their plantations arrive at a given or marketable size quicker than the trees of an unthinned

wood. This is undoubtedly the case, and if quality be no consideration, then the freely-thinned wood will probably prove the more profitable of the two. But can quality be ignored in the produce of a plantation which is intended to show a profit? By quality, we mean the most prominent features of straightness of grain, and freedom from defects and coarse knots, and the greatest possible proportion of stem or bole to branches. As is well known, the chances of securing timber of high quality diminish as the distance between the trees at an early age increases, and this fact at once condemns free thinning. But to decide whether quality may be ignored or not we must see what the chief uses of British-grown timber are. Practically speaking, all timber is either used on the estate on which it is grown, or it finds its way into the timber-yards of provincial timber merchants. In the former case, its chief use is found in the erection of fencing, out-buildings of farms and cottages, manufacture of gates, estate implements, &c., according to the species of tree, and its adaptation for those purposes. For fencing, Larch and Oak are chiefly used, and the quality of the wood of the former depends more upon the soil on which it is grown than upon its sylvicultural treatment. In an ordinary plantation, healthy trees will always produce sufficiently good timber for fencing purposes, or for rougher kinds of estate work, even when thinned freely at all stages, owing to the tendency it has of losing its lower branches without great crowding. This tree therefore often gives best results when freely thinned. *A. C. Forbes.*

UNITED STATES.

THE APPLE CROP OF 1897.

It is but natural, says the *American Agriculturist*, that after the very pronounced over-production of old-established commercial Apple-orchards last year, and consequent weakened condition of trees, there should follow a reaction and rest-period, such as the season of 1897 now shows. The contrast in the distribution of the crop of winter fruit, so far as surplus Apples are concerned, is most marked. The districts which last year produced the heaviest, swelling the crop to the greatest on record, now show a most pronounced shortage; while other and new sections, coming into increasing prominence every year, have turned off a product liberal in the aggregate, though deficient compared with a full year. The commercial Apple crop of the United States is about two-thirds of an average, taking a series of years, and rather less than half the enormous record-breaking yield of 1896, with the quality likewise greatly deficient, taking the country as a whole.

The total crop of Apples of 1897 for the United States is estimated at 37,436,000 bushels, against nearly 70,000,000 bushels representing the crop of 1896. The crop of 1895 approximated 61,000,000 bushels, 1894 about 58,000,000; and in 1889, the United States census year, 57,000,000 bushels.

The distribution of the crop of winter Apples available for the American markets and for export is this year little less than unique. Not in years has there been such a uniformity of shortage and indifference in quality in the long recognised commercial Apple-belt of the middle and eastern States. Occasional counties here and there show brilliant exceptions in the way of really good crops and of fine quality.

In the central, west, and south-western States, an excellent promise early in the year gave way in August and September, through extensive and excessive heat and drought, to serious loss, but still leaving a quantity of Apples for market liberal in the aggregate. An important part of this western crop, however, is rather poor to common in quality. Summer and autumn fruit in the southern States has long since passed out of sight, although quite recently Virginia has been marketing some choice table varieties at high prices in the northern cities. Thus the Apple crop is greatly deficient in the east, irregular in the middle west, fair to good in the west.

As long ago as early last spring it was a generally accepted fact that nothing like the 1896 crop of Apples could be expected, this being the "off year," as orchards here so heavily twelve months ago. In the northern and eastern Apple-belt, orchards failed to bloom freely, yet many counties had a good show of blossoms, and a fair set of fruit. Unusual weather, however, with excessive rainfall, proved injurious, making the condition suitable for the rapid development of insect-pests, which were particularly

prevalent nearly everywhere. Owing to the big crop a year ago, and possibly in part to low prices, very many orchards were neglected, spraying was insufficient or improperly done, and insects held fall sway. Such fruit as remained on the trees through the summer was in a very great number of instances imperfectly formed, gnarled and wormy, particularly in the older part of the commercial Apple-belt. Late summer and autumn weather conditions were fairly favourable for the final development of the fruit, with the exception of the central and south-western States, where excessive heat caused Apples to ripen prematurely or shrivelled on the trees, enormous quantities dropping to the ground scarcely suitable for cider purposes. The quality of New England's short crop is poor, as a whole; in the older central and middle States only fair to decidedly poor; in the west not high, other States are showing satisfactory quality. A good many young orchards are coming into bearing in the south-west. Owing to damage wrought by the recent drought, large quantities of this fruit have been sent to evaporators, thus disappearing from available supplies. *J. J. Willis.*

(To be continued.)

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Propagating Gooseberries and Currants.—The present is a good time to put in cuttings of Gooseberries and Currants, selecting for this purpose strong shoots, taking them off close to the branch. The cuttings should measure 1 foot in length, the lower part of a shoot being chosen, and all the buds on the lower half should be removed clean with a knife, so as to ensure a stem without suckers. The cutting-bed should have been recently manured, and the cuttings may be placed upright, at 6 inches apart, in trenches cut out as the ground is being dug, at 1 foot apart treading, the soil firmly on either side of the rows. Let each variety be securely labelled with its name, the labels being stout ones, capable of lasting two or three years.

Transplanting Last Year's Cuttings.—Plants raised from cuttings last year may be transplanted at any open time during the winter into preparatory or nurse beds at 15 inches apart, first affording the ground a dressing of short manure, and planting in the same manure as cuttings, so as to avoid trampling the land. Each plant should have its main roots shortened a little, and have the soil made firm about the roots. A mulch may be applied forthwith as a protection against frost.

Plantations of Raspberries.—New plantations may still be made of strong canes, putting them in rows from 4 to 5 feet apart, on well-manured, trenched ground, allowing a space of from 6 to 12 inches between the canes if they are strong. The varieties Superlative, Hornet, and Carter's Prolific are everything that can be desired for summer-bearing, being robust of growth, of great cropping capabilities, and the fruits of large size, solid, and of good flavour. I need hardly state that the weight, size, and quality of a crop, like that of any other kind of fruit, are nearly always proportionate to the depth, texture, richness, and retentive character of the soil. If a plantation is well managed, the crops obtained in the generality of years are very remunerative.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Laton Hall Park, Luton.

The Greenhouse, or Show-house.—The plants in this building should be re-arranged as regards the flowering subjects once a fortnight, turning plants round that are likely to spoil by becoming drawn to one side more than another, washing conserves from the pots, and stirring slightly the surface of the soil of pots, tubs, and borders, and clearing away everything that savours of decay, or is likely unduly to harbour damp. Afford water to those plants that need any early in the morning, mopping up what is spilled on the floor staging, &c. Great care must be taken that none of the plants is water-logged, this being a serious matter at this season. No plant should be placed in this house unless it is quite clean and free from injurious insects, and moreover is properly trained when that is necessary.

Ericas and Epacris.—Some of these will now be coming into bloom, and in order to keep them presentable for as long a period of time as possible,

the bulk of them should be placed at the cooler part of the house, and a close watch kept for mildew on the Erics, applying flowers-of-sulphur on its appearance. *Daphne indica*, greenhouse *Rhododendrons*, *Boronia*, *Phenocomas*, and other hard wooded plants, and *Epiphyllum truncatum*, should be raised above the general level or placed on shelves, so that air may reach every part, otherwise for lack of air and light the lower shoots of some of them may die, and the beauty of the plants be destroyed. Let the decaying leaves be removed from roof-creepers, and from *Camellias* secured to pillars and walls; and on days when the men cannot be employed out of doors, endeavour to get the leaves of *Camellias*, *Indiarubber*, *Orange-trees*, *Palms*, *Aspidistras*, &c., freed from dust, black-fungus, scale, &c., in some cases by dry rubbing, and in others by the use of soap and water, or an insecticide of some kind, or simply by using clean water and the syringe. The temperature may now range in the intermediate-house from 50° at night, and 55° to 60° by day, and in the cool-house from 42° to 45° at night, and 50° to 55° by day.

Creeping and Climbing Plants.—The time has arrived when plants of *Allamanda* of species, *Stephanotis floribunda*, &c., may receive their annual pruning. In the case of the latter, a partial thinning-out of the weaker shoots will suffice, the shorter laterals and spurs being left to produce flowers, these being tied-in loosely, or left untouched, as may appear best suited to the position the plants occupy. *Clerodendron Balfourianum* and *Dipladenias* should be treated similarly. *Allamandas*, *Bougainvilleas*, and *Codiaeums* (*Crotons*) should be pruned hard, assuming that the soil at the roots is dry, and they have been prepared as was advised previously. In the case of the *Ixoras*, these should have the weakest shoots cut back, leaving the others unpruned.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, late of Eastnor Castle, Ledbury.

Early Vinery.—If permanent Vines have to supply the earliest fruit for cutting in the spring, they are probably already subjected to a forcing atmosphere, and will need to be treated as advised in last week's Calendar for pot-Vines. Should, however, the Grapes be not required before the end of May or beginning of June, the early part of December is quite early enough to start the Vines. At the same time, it is good policy to commence early enough in all cases, so as to render unnecessary any hard forcing later on; and especially is this desirable in the case of late Grapes. Lack of colour in such Grapes as *Gros Colmar* is more often due to the Vine having insufficient time to perfect the berries. If the house be kept close, and have a night temperature of 45° to 50°, this is sufficiently high at first; and if fermenting materials are used, very little fire-heat is required during the first few weeks. When the Vines show signs of growth, the temperature may be increased 5° at a time. A good soaking of warm water of a temperature of 85° to 90° is very needful, especially if the borders are shallow. Syringe the rods thoroughly three times each day, till the buds have burst. In succession-houses the work of cleaning and painting should be pushed on as fast as possible. Houses containing late varieties with fruit still hanging will require careful firing and ventilation, and a regular temperature of 50° to 55° at night, with a rise of 5° by day. If good facilities are possessed for bottling and keeping Grapes, I should not hesitate to cut and bottle the bunches without delay. A still, fine day should be chosen for this work, and the greatest care used in handling the bunches, especially *Muscats*. If the Grapes can be bottled, the houses may be thrown open for a longer period than if the Grapes are kept hanging on the Vines till the new year. When these late Vines are pruned, it is essential to secure a good plump eye, even if it should result in having longer spurs than one would wish. In the case of *Muscats*, do not omit to touch the wounds with styptic, as once a Vine commences to bleed in the spring, it is a very difficult matter to stop the bleeding, especially when the Vine is young and vigorous.

Early Peach-house.—If this house was started early in November, the buds will be now swelling fast, and should the weather be mild the temperature may be increased a little. As soon as the flower-buds commence to show colour, syringing must be done much more lightly; and it is a good preventive of green-fly to give the trees at this stage a good fumigating with strong tobacco-paper. By the same means, black-fly (should it be present) may be kept down till the setting period is well past. Give air on all favourable occasions, if only for a short time. Continue pruning and cleaning

operations in all the later houses, keeping the trees as quiet as possible. To this end, tender plants should be excluded from late Peach-houses, as a thorough rest for the trees is imperative if first-class fruit is required.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Laelia pumila, *L. p. Dayana*, and *L. p. prestans*.—These dwarf-growing Orchids are charming when in flower, and, being now imported freely, they are easily procured. At the present time, the plants generally will be going out of flower, and any which require fresh rooting material may forthwith be attended to, roots from the current season's growth soon entering the fresh potting-materials. Small shallow pans are more suitable than pots or baskets, and these should be three parts filled with drainage, and only a small quantity of peat and moss put in for the plants to root into. After affording fresh compost, suspend the plants near to the roof in the coolest part of the *Cattleya* or Intermediate-house, where, during winter, they may receive the maximum of light. While the plants continue to make roots, the compost should be kept fairly moist, but when at rest very little water is needed, only so much as will prevent the pseudo-bulbs from shrivelling.

Chysis Cheloni, *C. Sedeni*, *C. bracteescens*, *C. Limminghei*, and *C. laevis*.—Those plants whose pseudo-bulbs have attained their full size should now be suspended in a light part of the *Cattleya*-house, and from the present time until the leaves turn yellow and fall off, the quantity of water afforded them should be gradually diminished; and after the leaves have fallen, and the new pseudo-bulbs have been properly matured, scarcely any water will be needed during the period of rest. In order to bloom these plants satisfactorily, they require a long period of decided rest.

Trichopilia fragrans.—This is one of the best, white-flowered, fragrant Orchids now flowering, and it is generally known in gardens as *Pilumna nobilis*. The plant should be kept at the warmest part of the *Odontoglossum*-house, or in any moist house where the winter temperature does not fall below 50°. It requires a light position, but if exposed to bright sunshine, its naturally dark green leaves quickly become of a yellowish hue. Enough water should be afforded as will keep the compost moist when the plant is in bloom; and during the growing period it should be treated in the matter of water like the *Odontoglossums*. Re-potting may be performed at almost any time during the winter months. A well-drained pot is more suitable than a basket, and as a strong healthy plant will produce a great number of roots, the pot should be of considerable size. In potting keep the plant well raised, so that it can easily be watered without danger of water lodging in the young breaks, as these quickly turn black and decay when this happens. *T. laxa*, coming from the same locality as *T. fragrans*, will also do well under the same kind of treatment. *T. suavis*, *T. s. alba*, *T. marginata* (*crispa*), *T. tortile*, *T. Galleotians*, and *T. coccinea* all require a few degrees more heat. The majority of these species have now completed their growth, and care must be taken not to over-water them, or their leaves will become spotted. Those plants that are still growing should be placed in the East Indian house until the pseudo-bulbs are made up. The resting plants are better for being suspended or stood near to the roof of the intermediate house.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maidenhead.

Dahlia tubers that have been placed in frames or sheds in order to let the sap dry out of the stems, should be stored in a place that is out of the reach of frost, but not excessively dry.

Helleborus niger.—If this plant is throwing up its flowers, afford it the protection of a hand-glass, or where it is growing in masses that of a frame. Oak branches to which the leaves are still adhering stuck in the ground and bent over them protect the blossoms somewhat, cause the flower-stalks to grow longer, and the blooms to come of a purer white than is the case when glass is used.

General Work.—A good deal of labour must necessarily be devoted to the clearing-up of fallen leaves at this season; the leaves on walks and the outskirts of shrubbery borders, in the garden and pleasure-grounds, and on the lawns being raked up, and carted away without much delay, failure to perform the latter often leading to a repetition of

the work. After this is done, the broom must be employed to complete the job. All Beech, Oak, and Sweet Chestnut leaves should be put into a heap by themselves to be used in hotbeds, &c., and also for rotting for the production of pure leaf-mould. Other leaves will, of course, make mould, but it is not so good for potting purposes, although very suitable as a dressing for flower-beds, shrubbery borders and other rougher uses. After the clearing-up is finished, walks and lawns, and verges should be rolled, rolling being repeated at fortnightly intervals during open weather. If the lawn grows much moss, which is almost always the case if tree-shaded or ill-drained, it should be scratched up with a small fine-toothed rake, and having cleared it away, a top-dressing of fine loamy soil, wood-ashes, soot, and lime should be applied, the last three amounting to one-fifth of the whole, and with which they should be well mixed. Let the dressing be spread thinly, and then brushed in with new brooms. A very wet lawn is never pleasant to walk upon, and the finer kinds of grasses do not succeed on it, and it is generally worth the while to drain it with pipes or rubble drains, this kind of work being carried out in the winter season. If the turf requires to be made level, it may now be taken off, cutting the turves of 3 feet by 1 foot, or of 1 foot square—of the latter size if it be a light sandy soil, and the turf is lacking in toughness. Let the turves be stacked close by the part that is being dealt with. Having removed the turf, prick up the surface, adding fresh soil where found necessary, and rake it level, then trample it firmly, and carefully relay the turf, beating it down firmly. The re-gravelling or turning of dirty walks may be undertaken now, first breaking up the gravel with digging-forks or picks. Although this kind of work is best carried out in the spring months, it may be undertaken at this season in dry weather.

THE KITCHEN GARDEN.

By W. H. POPE, Gardener, Highclere Castle, Newbury.

Asparagus, Dressing for the Winter, Forcing, &c.—If the clearing of *Asparagus*-beds has been neglected to this date, there should be no further delay. After clearing away the decaying tops and all weeds, and drawing some of the soil into the alleys, afford the beds a heavy dressing of rich manure; and then, with the spade and line, chop down the sides of the beds, and spread a little of the soil thus thrown into the alleys over the manure. This will give a tidy look to the beds, and prevent the manure from being disturbed by the birds. The alleys may then be dug. If *Asparagus* is grown in isolated rows on the level, the manure cannot well be covered with earth; but after clearing of the tops, &c., as in the other case, a dressing should be afforded on both sides of the rows for a distance of 2 feet, any rough portions remaining after the winter being raked off in March or April.

Forcing Asparagus.—Another lot of roots may now be got into the forcing-pit, which will probably enable the supply to extend to the New Year. *Asparagus* is readily forced at this season, and when the roots have been well prepared, good produce may be expected. The best roots are those that have been well grown from seed, are four or five years old, and have not been weakened by spring cutting. To do this involves the sowing or planting the required number of roots annually. To keep up a regular supply, fresh roots should be put into heat soon after the heads from the previous batch are fit for consumption. The best and most economical method is to have beds which, by means of hot-water pipes or fermenting materials, can be forced on the ground with shutters, the sides being supported by brick-work and the top of the beds.

Seakale.—Maintain the supply of *Seakale* by the introduction of fresh roots at short intervals, and although forcing is easier now than earlier, it is scarcely possible to have *Seakale* fit for table in less than four weeks. One manner of forcing is to select strong crowns, and dibble them rather thickly into 10 or 12-inch pots, plunging these up to the rim in a gentle hotbed, affording tepid water to settle and moisten the soil. A few pots thus forwarded in heat, weekly, will keep up a regular supply; but the roots must be kept moist, or the produce will be tough, and total darkness is essential for blanching.

Forced Chicory.—*Chicory*-roots may now be placed in warmth for the production of blanched leaves, the same methods being followed as with *Seakale*. After the new year, *Chicory* forces well without bottom-heat in a temperature of 55° to 60°.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, DEC. 7 { National Chrysanthemum Society's Winter Show, in the Royal Aquarium, Westminster (3 days).

SALES.

MONDAY, DEC. 6 { Dutch Bulbs, Roses, &c., at Protheroe & Morris' Rooms.

TUESDAY, DEC. 7 { Continental Plants, Dutch Bulbs, Herbaceous Plants, &c., at Protheroe & Morris' Rooms.

WEDNESDAY, DEC. 8 { Japanese Lilies, Continental Plants, Palm Seeds, Roses, Gladioli, &c., at Protheroe & Morris' Rooms.

WEDNESDAY, DEC. 8 { Unreserved Clearance Sale of Fruit Trees and Plants in pots, at the Manor House, Southfleet, by order of Mr. W. Chambers, by Protheroe & Morris.

THURSDAY, DEC. 9 { Great Unreserved Clearance Sale of Nursery Stock, at the Barn Elm Nursery, Lower Richmond Road, Putney, by order of Mr. Holmes, by Protheroe & Morris.

FRIDAY, DEC. 10 { Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick. —41°.

ACTUAL TEMPERATURES:—

LONDON.—December 1 (6 P.M.): Max., 47°; Min., 39°.

PROVINCES.—December 1 (6 P.M.): Max., 46°, Valencia; Min., 37°, Aberdeen and York.

Wind, colder; snow in the Lothians and in the Midlands.

JAMES BATEMAN.

"ON November 27, at his residence, Spring Bank, Victoria Road, Worthing, JAMES BATEMAN, M.A., F.R.S., aged 87." It is thus that in the fewest words is dismissed, in the columns of the *Times*, one of the most remarkable men in the horticultural world that the century has seen. Early imbued with a taste for plants, he, even when a gentleman-commoner at Magdalen (we doubt if there is such a thing now), showed the bent of his mind. DAUBENY was not even at that time Professor of Botany, or he might have overlooked the venial delinquencies of the undergraduate. At this early date, too, BATEMAN made the acquaintance of LINDLEY, and his tendencies towards Orchid lore and Orchid culture must have been materially strengthened by the intimacy. At this time, as we have heard, BATEMAN was a dandy, and, as such, would not have been looked on with much favour by LINDLEY; but perhaps the love for Orchids was considered a "forte" sufficiently important to compensate for the foible. In later years, BATEMAN took much interest in church matters, espousing warmly the Evangelical cause, and at one time, if we mistake not, serving as editor of the *Rock*.

It is not with such details, however, that we have to concern ourselves; we have to remember him as one of the very first and

most enthusiastic cultivators of Orchids, the creator of two of the most remarkable gardens in the kingdom, one at Knyppersley, the other on a much smaller scale at Worthing. Both these were described in the *Gardeners' Chronicle*, so that we need not refer to them again. The older Fellows of the Royal Horticultural Society will not forget Mr. BATEMAN's pleasant little discourses at the Society's meetings, when he succeeded in giving an amusing and interesting description of the plants exhibited. Mr. BATEMAN has also the credit of having produced the largest book in existence, or at any rate the largest botanical book. This is his *Orchidaceae of Mexico and Guatemala*, superbly illustrated with coloured plates, and with numerous humorous woodcuts by CRUIKSHANK. This splendid volume is in the Lindley library, and is the biggest book in the collection, as we believe it is also in the library at Kew. It is needless to add that this is one of the books which the trustees of the Lindley library would not feel themselves at liberty to lend out!

We do not know that we can do better than repeat what we said in 1871 respecting Mr. BATEMAN's career, and present the portrait of him in his prime on p. 403. Of late years increasing infirmities prevented him from being much among us, but many will remember the occasion when, a year or two ago, he received at a meeting of the Royal Horticultural Society the Veitchian Medal. Surely no one earned that distinction more fully.

Mr. BATEMAN has now for many years been known as an ardent and enthusiastic horticulturist—not so exclusively devoted to Orchids as might be supposed from some of his utterances, though truly they have been to him, so far as plants are concerned, the master passion of his life. They were not, however, his first love, for while still a very young man he took great interest in the cultivation of tropical fruits, and amongst other things succeeded in fruiting, at Knyppersley, for the first time in England, the Carambola, *Averrhoa Carambola*, of which a coloured plate appeared in the "Transactions of the Horticultural Society." Now and then there have been symptoms of a return to his first love, as happened a year or two since, when the Wampee, *Cookia punctata*, was exhibited at one of the meetings of the Royal Horticultural Society; indeed, it rarely happens that a tropical fruit of any kind is shown but that Mr. BATEMAN is stimulated by his old zeal to communicate the knowledge he possesses as to its history and cultivation. The allusion to this circumstance at once leads us to make mention of those pleasant lectures—lecturats, as Prof. HENSLow would have called them—which Mr. BATEMAN has been in the habit of giving at the Royal Horticultural Society from time to time for some years past, and in which he contrives to convey a great deal of valuable and interesting information in a pleasant gossiping style.

Now and then autobiographical details are interspersed in the most natural way with the remarks on plants and how to grow them. Thus many who read these lines must have heard how the exhibition of a coloured plate of *Renanthera coccinea* to Mr. BATEMAN awoke the latent passion for Orchids, and how the first Orchid was purchased—a plant of *Renanthera*—of FAIRBAIRN, a nurseryman at Oxford, who had formerly been in the service of Sir JOSEPH BANKS; and how, still dotting over the glories of the *Renanthera*, Mr. BATEMAN, then a gentleman-commoner of Magdalen College, Oxford, incurred the wrath of the Vice-President of the College—no less a person than Dr. DAUBENY, who subsequently became Professor of Botany in the University. The wrath of the Vice-President was occasioned by the fact that the rules which those in *statu pupillari* are bound to obey had been infringed by Mr. BATEMAN, as the charms of *Renanthera* proved a stronger attraction even than the architectural beauty of Magdalen, and detained the undergraduate beyond the prescribed period. The punishment

awarded for this misdemeanor was not, as might have been expected, the compulsory eulogium in the choicest Greek iambics of the syren *Renanthera*, but took the shape of a command to write out half the *Palms*, wherein, so far as we remember, no special allusion is made to any of the Orchid family.

Botany was at a very low ebb at that time in the University. Dr. DAUBENY, who afterwards did so much for that and other sciences, had not then acquired the position and influence which subsequently he exercised with so much power and discretion to advance the cause of natural science. But although Mr. BATEMAN's botanical proclivities met with little encouragement on the part of his *alma mater*, they were more favourably regarded by others. Encouraged by his father's support and assistance, Mr. BATEMAN despatched a botanical collector, the late Mr. COLLEY, to Demerara and Berbice. An account of this expedition—one of the first of Mr. BATEMAN's contributions to horticultural literature—was published in "London's Gardeners' Magazine." The results, however, of this journey were not remarkable, the Orchids obtained were few in number, and of no special beauty or interest. The novelties obtained were not numerous; to one of them, one of the ugliest as it happens, Dr. LINDLEY affixed the names of *Batemannia Colleyi*, thus associating the names of employer and collector. A short time afterwards Mr. BATEMAN made the acquaintance of the late Mr. G. URE SKINNER, then resident in Guatemala, and the friendship then inaugurated proved of the greatest service to the two persons most concerned, and promoted in no ordinary degree the knowledge of Orchids, and their diffusion among the cultivators of Europe. Thanks to the energy of Mr. SKINNER, numerous Orchids were collected and introduced to our stoves, and abundant material placed at Mr. BATEMAN's disposal for use in his work on the "Orchidaceae of Mexico and Guatemala," atlas folio, 1837—41. This work, in some respects the most remarkable series of plates ever published, demands a few words of notice at our hands, inasmuch as from its costliness and size, and the limited number of impressions struck off, it is not readily accessible to the majority of horticulturists.

It consists of a series of coloured illustrations, of life-size, of a great number of species of Orchids accompanied with descriptive details and cultural hints. It is worth while recording some of Mr. BATEMAN's axioms on this latter point. The plants, says he, can scarcely have too much light or too little sun. Take care of the roots. Beware of noxious insects. Give the plants a rest. Attend to the condition of the air; let it have on the average a temperature of 60° in winter, and of 75° in summer. Do not over-water. These directions were written before the days of cool Orchid culture, to which, however, Mr. BATEMAN subsequently became a convert and zealous proselyte, as witness his lecture on cool Orchids before the Royal Horticultural Society in 1864. But to return to Mr. BATEMAN's *magna biblion*. The illustrations are accompanied not only with suitable descriptions and hints for culture, but with little scraps of gossip, if we may so call them—literary, scientific, archaeological, or ethnological gossip, as the case may be, but in any case noteworthy for its elegant piquancy of style, and for the singularly felicitous choices of classical quotations. The humorous sketches and tail-pieces of GEORGE CRUIKSHANK also lend a zest to this, in many respects, unique publication.

During the progress of this work Mr. BATEMAN married, and by happy good fortune Mrs. BATEMAN shared her husband's love of plants, and zeal in their culture. But while Orchids were the chief subjects of Mr. BATEMAN's regards, hardy plants occupied the first place in the regards of his spouse. Hence arose those gardens at Biddulph Grange and Knyppersley, which have attracted so much attention from their artistic disposition, and the vast number of beautiful and interesting plants which they contained. Were we to tell of all the noteworthy features of the gardens at Biddulph Grange, we should require several numbers of the *Gardeners' Chronicle*. Those who would know of the Chinese garden—a realisation in the garden

of the Willow-pattern plate—the Egyptian Court, the Wellingtonia Avenue, the Grove of Sikkim Rhododendrons, the Bulb Garden, the Dahlia Garden, the Rose Garden, the Pinetum, the Stumpery, the Tree Pæonies, the Orchids, of course, and a host of other things,—we would refer to the lengthened notices given in these columns in 1856, and 1862, by Mr. KEMP and Mr. ANDERSON. Suffice it here to say,

advantage of affording endless variety at all seasons. Moreover, it enabled Mr. BATEMAN, as a true lover of plants, to place each plant, so to speak, in the place and under the conditions most suitable to its requirements. It would not be fair to infer that the art of the landscape gardener was entirely subordinated to the solicitude of the cultivator; rather let us say that the landscape gardener, in this case, did what

as, in addition to his own good taste and feeling for the appropriate, he was aided by [the late] Mr. E. W. COOKE, the eminent painter, and, we may also write, plant-lover.

The partiality for the quaint, we may incidentally mention, shows itself in the "Orchidaceæ of Mexico and Guatemala," where many a "quaint conceit," will be found, both literary and illustrative.

FIG. 117.—PASSIFLORA PRUINOSA, N. SP.: SEALS WHITISH, PETALS FLUSHED WITH BLUE; THREADS DEEP BLUE.

Section of the flower to the left—s, sepal; p, petal; n, outer rays of corona. (See p. 393.)

in general terms, that by skilful arrangement of artificial hill and dale, a wonderful diversity of surface was obtained, and a number of distinct sections parcelled out, each devoted to a particular purpose, as may be gathered from what has been readily said. If this multiplication of parts interred with the breadth and repose one looks for in garden of such pretensions, it had the compensating

landscape gardeners do not always do, study the welfare of the plant as much as the effect it produces. Some of the effects, from a landscape gardener's point of view, were strikingly beautiful, many quaint and grotesque. Had these latter been carried out by a person of less natural taste than Mr. BATEMAN, they would have degenerated into the cockney style. In Mr. BATEMAN's case, there was the less risk of this

Unfortunately, however, the ungenial climate of North Staffordshire was as unfavourable to the health of Mrs. BATEMAN as it was unsuitable for gardening pursuits. Quitting then a spot which will always hold a very high place in the annals of horticulture, Mr. BATEMAN came some few years since to reside principally in Kensington, in close proximity to the Royal Horticultural Society, in whose fortunes he has

matters. We have cited the figures approximately, but they are sufficient to show what a valuable plant Buckwheat is when cereals fail.

OPEN SPACES IN LONDON.—It may be worth while to make a note of the following, from a report just issued by the Parks Committee of the London County Council. The open spaces, churchyards, &c., in the county of less than 10 acres in area, which are at present kept up for the enjoyment of the public, number 203, having an aggregate area of 366½ acres.

that the girth of the tree, No. 1, mentioned at p. 385, is 9 feet 3½ inches, instead of 6 feet 3½ inches.

BARON SIR FERDINAND VON MUELLER.—It is with much satisfaction that we announce the intention of the executors of the late SIR FERDINAND VON MUELLER to erect a monument in the St. Kilda Cemetery, Melbourne, to the memory of the great botanist. The BARON's services were by no means confined to his adopted country. Not a country in the civilised world but benefited by his labours;

on Thursday, December 9, at 3.30 P.M., to receive the report of the committee, to pass the accounts, to elect the committee and officers for the ensuing year, and for the transaction of other general business:—

PROPOSED ALTERATIONS OF THE BY-LAWS AND REGULATIONS.

1. To alter By-law 5 so as to read—"Notice of any proposed alteration of these By-laws must be given in writing to one of the Secretaries at least two weeks before a general meeting, and no by-law nor regulation shall be altered except at a general meeting of the society. A special general meeting of the society may be called at any time on a requisition, signed by not less than twenty members, being delivered to one of the Secretaries at least fourteen days prior to the date of the proposed meeting. The requisition must specify the business for which the meeting is called, and no other business shall be transacted thereat."
2. To alter By-law 7 so as to read—"That the Committee shall, at its first Meeting, appoint a Sub-Committee (to be styled the General Purposes Committee) not exceeding ten in number, for the purpose of considering and reporting upon any matters connected with the society which may be brought before the Sub-Committee, by notice to the Secretaries of the society, and that the functions of that Sub-Committee shall endure until the next Annual General Meeting of the society. The Sub-Committee to have no executive power whatever."
3. To alter Regulation 8 so as to read—"All Roses must be exhibited as cut from the plants. Artificial aid of any and every kind is strictly prohibited, with the exception of wire or other supports, which are only to be used to keep the blooms erect. A bloom left tied will not be counted by the judges. Dressing Roses so as to alter their character is prohibited. A bloom so dressed will be counted as a bad bloom. The insertion of any additional foliage will disqualify the stand. All Roses should be correctly named."
4. New Regulation (transferred from authorised Rules for Judging at Rose Shows).—Exhibition stands should be of the regulation size, viz., 4 inches high in front and 18 inches wide, and be set out with moss or other suitable material. They should also be of a uniform length, viz.:—
For 24 blooms, not less than 3 ft., or more than 3 ft. 6 in.
" 12 " " 1 ft. 6 in. " 2 ft.
" 6 or 9 " " 1 ft. " 1 ft. 6 in.

HOME CORRESPONDENCE.

MUSCAT OF ALEXANDRIA GRAPES.—The matter in dispute between Mr. Smith and the writer on certain points connected with the culture of this Grape has brought forth a challenge which I would fain accept. But I am afraid the editor would not open these pages to a contest which would not be edifying generally, and only instructive in one sense. I may say, however, my interest and experience in Grape growing extend over thirty years, and I can also claim a fair amount of success on the exhibition-table during most of that time. Besides, my experience in this line has been before the public for a decade, and I see no need to change the views I previously entertained and expressed on the points at issue. And it is just because these views do not exactly agree with those expressed by Mr. Smith, that I ventured to criticise his remarks. In his first letter he directed our attention to the necessity of careful ventilation in autumn to secure good flavour, giving one to believe that this was the time most careful ventilation was needed; but in the letter now before me he is for ventilation—I presume "careful"—all the year round. Well, we may now agree on this point; but Mr. Smith has misrepresented me by saying I advised the putting on of a "lot" of air the first thing in the morning. I spoke of timely ventilation in the morning, and also preparing for a sudden outburst of sun in the middle of the day after a dull forenoon; but I never advocated a lot of air being put on at one time. This operation must be gradual as the temperature rises. The most serious difference between us is in regard to shading. I have never been at Hendon, where Mr. Smith labours, or near the place, and if the sun has more power there than it has in Scotland, he may be justified in recommending a shade for Muscats. He must, however, have been aware that we read the *Gardeners' Chronicle* north here, therefore his instructions should have been localised. I may say we never require to shade in Scotland when the heating is properly seen to, and the airing as recommended in my last letter. Early closing and syringing are outside the question under discussion, points, however, upon which we seem to agree. I would now ask Mr. Smith to give us the experience upon which he prides himself, and I will undertake

PORTRAIT OF THE LATE MR. JAMES BATEMAN, F.R.S., TAKEN IN 1871.

(See p. 400.)

Of these, 122½ acres are maintained by the council, 42½ by vicars, rectors, or churchwardens, 27½ by the government, and 16½ by the vestry of St. Pancras.

THE WELLINGTONIA.—A letter from a correspondent last week contained an erroneous date, which we are sorry to say we overlooked. It has brought us a shoal of communications, which we are in one sense very glad to receive, as it shows that great interest is taken in such matters; and, moreover, that our readers are neither few nor indiscriminating. The Wellingtonia (*Sequoia gigantea*) was discovered and introduced by WILLIAM LOBB in 1853, so that it could not have been planted in 1816, as stated by our correspondent. We should also state

scarcely a botanist in the world but was in communication with him. The Rev. W. POTTER "VON MUELLER," Arnold Street, South Yarra, Victoria, should have no difficulty in getting the sum he requires many times over.

LEO. GRINDON.—The friends of this genial and hardworking botanist are taking steps to celebrate his eightieth birthday with fitting compliment and celebration. Mr. GRINDON has done excellent work for Manchester, and for botany generally.

NATIONAL ROSE SOCIETY.—The twenty-first annual general meeting of the National Rose Society will take place at the Rooms of the Horticultural Club, Hotel Windsor, Victoria Street, Westminster,

to kick holes in it if I find the least opening. I would give my name and address for publication if this was a general rule, meantime, I give my initials, W. W. [We have our correspondent's name and address, Ed.]

FRUIT JUDGING.—There is frequently a rule in schedules stating that all fruit in certain classes must be ripe and fit for use, but we seldom see Grapes in this condition at early autumn shows, unless it be Hamburg and other early sorts. Under these circumstances, unripe Grapes are not disqualified, and ripeness becomes a matter of degree. A notable judge was once heard to say, when judging Grapes, that "ripeness was his first consideration." This doctrine, however, is often carried too far, and 1st prizes are awarded to varieties fully ripe, but without any cultural merit, while other well-cultivated Grapes are passed because not fully ripe. Such varieties as Alicante, Gros Maroc, and others that colour well, and acquire bloom long before ripe, have an advantage against white sorts just as ripe, especially Muscat of Alexandria, which is often in better condition for the table, though not finished, than well-coloured black varieties. It would be best if all Grapes were ripe when exhibited, but as this condition is not enforced, superior varieties would in competition be placed on more equal terms were the points for relative value allowed as described in my last letter, because it is invariably the best varieties, excluding the Hamburg, which take longest time to colour well. In regard to mixed collections of fruit, there is more difference of opinion on the relative merit of kinds than in classes represented by distinct varieties only. When the same varieties of the kinds are opposed in collections, which is rarely the case, a judge sometimes places the merits of the one against the other, on the ground that a good dish of small fruits, such as Cherries or Plums, is equal in value to a good dish of large fruits, such as Grapes or Peaches. Suppose two collections requiring to be pointed are composed of the usual kinds, and it is agreed to allow five points as a maximum for good dishes. The Pines, we will suppose, are equal, but there is a difference of two points in the Grapes; there is then give-and-take down to the last dish (Cherries), where a difference occurs again of two points. The points gained therefore by superior Grapes are lost by inferior Cherries. The collections show equal totals, but it is a result which would not be received with favour generally. To obviate the chances of an occurrence of this kind, a graduated scale is needed, similar to the one recommended for the different varieties of Grapes in the *Gardeners' Chronicle* for September 11, p. 136. In answer to the Editor's question on p. 314, *re* the code of rules issued by the Royal Horticultural Society, it would have been a serious waste of time had not some help been derived from the code, which was the subject of a whole year's consideration by some of the most eminent horticulturists. Fruit, however, was very sparingly dealt with, and a system of judging collections was entirely omitted, a fact that was the subject of comment in these columns after the rules were published. The excuse given by one of the members of committee was, that the code should not be accepted as a final settlement, but that the next issue would rectify everything. The new rules have not yet seen the light (so far as I know), and the above hints are given in the hope that they may be useful when the matter is again under consideration. *Ayrshire Lad*.

ROYAL HORTICULTURAL SOCIETY'S MEDALS.

—Presumably, the Lindley medal, of which we have been of late reading, is one of the lapsed honours of horticulture that once constituted something worth having, because rarely bestowed. When that medal was granted, it is hardly probable that it was awarded to all and sundry at the rate of sixty a time. Evidently, it was given only for highly meritorious cultivation, and seldom, that made it an honour worth possessing. Why it has been allowed to lapse probably the council of the Royal Horticultural Society knows best. Possibly, the society's honorary gold medal has taken its place, a medal, apparently like the Lindley, awarded and not given. It would perhaps be just as well if the same course were adopted in regard to medals of lesser value, that are given now far too freely, and which seem to be sought for with an avidity that may be regarded almost as avariciousness. Honour derived from exhibiting good produce of any description from time to time seems to be almost swamped by the desire to secure the medal; but when got, of what value is it! There must be some exhibitors at the

society's meetings who could very well cover their rooms with these medals, and yet they are not content. Give them a bronze one, they rage; give a Banksian silver, they whine for a Knightian; and give a Knightian, they cry aloud for a silver-gilt, and even for a gold medal. All this seems to be very pitiful, and degrades horticulture. I am not sure whether it would not be good policy on the part of the Royal Horticultural Society to suspend medal-awarding absolutely, and thus strangle grumbling ere it is heard. *K*.

A SUCCESSFUL AMATEUR CULTIVATOR.—One has the pleasure occasionally of falling in with a genuine and enthusiastic amateur gardener, who finds in the cultivation of his flowers, fruit-trees, and vegetables the height of enjoyment. From an inspection of the garden of the true amateur horticulturist much may be learned. I recently made the acquaintance of a genial amateur, in Mr. Crowne, of the Box Trees, Long Ditton, whose favourite flower is the Chrysanthemum. His garden is not a large one, but is well filled, and in the summer when the Chrysanthemum-plants are standing outside, every nook and corner is utilised. The collection numbered some 300 plants, and it is no exaggeration to say that not a bad plant could be found among them. The varieties embrace the newest and best, and for a collection of its size, the selection of varieties would admit of little improvement. At the time of my visit to Mr. Crowne's garden the plants were in full splendour, and are arranged in two greenhouses, and forming a sight well worth going far to see. Many of the plants were represented by blooms of exhibition standard. Mr. Crowne has rendered a good account of himself at some of the exhibitions of recent years, having been awarded a Silver Medal by the National Chrysanthemum Society at their show of November 5, 1895, for an exhibit in the incurved section; the Silver Cup of the Ditton Chrysanthemum Society also found its way to the Box Trees on November 12, 1896; and but for just one or two little failings in the incurved stand, it would have brought the same result this year. At Kingston and Ditton he has been very successful with Chrysanthemums. *F. S. B. S.*

YORKSHIRE APPLES.—I thank Mr. Dixon, of Elmcroft, Ripon, and H. H. R. Forest Hill, for their reply to my note, *re* the above. I will try dressings of fresh lime, as recommended by Mr. Dixon, for Cox's Orange Pippin. I have tried lime-rubble and stick-ash freely mixed with the soil when root-pruning and planting, and in due time I hope to be able to report upon it. I will also try Ribston Pippin. I have Margil, which generally gives us a few useful fruits of excellent flavour. *T. Down, Wassand*.

THE GROWTH OF THE STEM OF AURICULAS.

—I read with much interest the article about the lecture of Prof. F. W. Oliver in the *Gardeners' Chronicle* of November 13. I can confirm the observations made by you about the growth of the stem of Auriculas. In April of this year I received a fine lot of *Primula elatior*, which grows wild in this country in some limited spots. I received the plants with a large clump of roots, to which the clayey soil still adhered. I put some of them into the open border, the others in pots only sufficiently large to contain the clumps. The growth was a little checked, but they soon recovered, bore some flowers, made a fair tuft of leaves, which decayed rather early. This and also the mild autumn weather is the reason that they are already showing their tufts of small, new leaves, and now all the plants in the open border are at the same level, while those in the pots project considerably above the margin. I suppose the situation of these latter may be compared with that of the *Primulas* growing in rocky clefts, and projecting their stems about the edges of the crevice. When planting these plants in pots, which, however, will seldom occur, it will be necessary to take this into account. *J. C. Bosch, Beverwijk, Haarlem, Nov. 17*.

TESTACELLA HALIOTIDEA.—Having been a close observer of these slugs for many years at Oxford, where they are fairly plentiful, perhaps the following notes may be acceptable. I have frequently seen them in the act of eating a worm. They seize them, not by the extreme end, but at about a third of their length, and at this point a wound is inflicted, and the worm is drawn in doubled up. It is a very long process, lasting sometimes for hours. I used to look for them on the lawns at night by lamplight, when I found them crawling on the grass, and altogether different from the "sluggish" contracted creatures which were dug up. I found them mostly in rich

loose earth at varying depths down to 18 inches. They could also be found in the daytime by turning up planks or bricks. The weight that they could support was astonishing. I kept many of them in a flower-pot covered with a paving-tile, and often found that they had succeeded in raising it sufficiently to escape, and have also watched them doing so. *Geo. Parish, Ealing, W.*

PERFECT SPECIMEN CHRYSANTHEMUMS.

Permit me a few lines to congratulate my old friend, Mr. Donald, of Short's Green, on his latest triumphs with specimen Chrysanthemums with from fifty to a hundred good blooms upon each, the plants from 1 to 2 yards across. Amid all the changes of fashion, Mr. Donald has pursued this art, and moulded many varieties into superb specimen plants for his big conservatory. His complete success has doubtless been his most pleasing and richest reward. But others, equally or more pleasant, are in store for him in the near future. These are the hearty approval of many of his practical brethren; and the highest compliment they can pay to his energy and perseverance, viz., imitation. Surely the one-bloom theory and practice on stems somewhere in mid-air, far above the sight lines of ordinary mortals, has well nigh had its day, and growers who desire their plants to be decorative ones, can hardly do better than grow such plants as does Mr. Donald. His troop of friends everywhere hope he may yet be long spared to win many other victories as those he has so honourably won. To those who tell us that specimen Chrysanthemums are not natural, I reply they are far more so than the one-stem single-bloom monsters mounted on bamboos in mid-air, and which we have to mount on ladders, steps, or stages to see, touch, cut, or enjoy. *D. T. Fish, 12, Fettes Row, Edinburgh*. [Mr. Donald's plants are magnificent specimens for exhibition, and are very high-class examples of the trainer's art. For the decoration of rooms, however, they are less adapted than well-grown bush-plants with a dozen stems upon each, and every stem bearing one moderately-sized bloom. Such plants can be associated with other decorative subjects to much better effect. Further, other points being equal, the cost of production in each case may be fairly considered, and in the case of trained specimen plants this must be a serious matter. Our correspondent, too, when speaking of Chrysanthemums in "mid-air," that can only be seen by first mounting a ladder, appears not to bear in mind there has taken place a great improvement in the habit of Chrysanthemum plants, and many of the newer varieties grow little taller (under proper culture) than such as *Avalanche*—say, 3 to 4 feet. Mr. Fish, of course, is speaking of plants grown exclusively for the production of large exhibition blooms; but even in such cases, many growers obtain three flowers per plant, unless from exceptional varieties. Ed.]

NERINE CRISPA.—I was much impressed with the beauty and apparent usefulness of a nice batch of plants grown under the name of *Nerine crisper*, is one of Sir C. W. Strickland's houses at Hildenley, a short time ago. There were about twelve bulbs in each of the 5-inch pots, and each bulb had produced a flower-spike about 15 inches long, and each spike bore ten or a dozen flowers. The sepals were long and narrow, and either twisted or turned up at the ends, and of a pale pink colour. The leaves were narrow and grass-like, and the whole formed beautiful and graceful subjects for dinner-table work, or the adornment of the drawing-room. Mr. Smith, Sir Charles' indoor gardener, told me that they were most easy to cultivate, and under ordinary treatment would grow and flower freely. Several representatives of the large-flowered kinds were present, but although the colour, form, and substance of their blossoms were all that could be desired, yet they lacked the delightfully light, graceful habit, and delicate tint of *crispa*. Where there is much table-work, this variety would be found a decidedly valuable addition to the subjects for that purpose, and one not requiring an exceptionally high temperature, or much skill in its cultivation. *R. C. H.*

ROSES.—The mildness of the season enabled me to gather 100 blossoms on November 20, and some of which were very fine, amongst those flowering freely may be mentioned *Souvenir de la Malmaison*, *Homère*, *Madame Faloot*, *Celine Forestier*, *Gloire de Dijon*, and many of the China varieties; the buds of the latter being very useful in decorative designs. The making of cuttings may still be carried on. This matter was touched upon in a recent "Calendar," by Mr. Herrin, and I will merely add,

that in cold soils it aids the rooting if the base of the cutting rest on sand. It is very necessary to make the soil firm about the cuttings, and to make it so when frost has loosened the ground. *H. M.*

"THE NEW FLORA BRITANNICA."—You are quite right in saying that this rare work is one "which

"Syd. T. Edwards, del." appears on plate 129 (*Amaryllis vittata*), with that of "W. Darton & Co., Sc." as engravers; and on t. 135 (*Gladiolus cardinalis*), we get "Syd. T. Edwards, del. et sculpt," apparently for the first time; the date August 1, 1790. The next plate has "Syd. T. Edwards, fecit," November 11, 1790. So much for the *Botanical*

subjects or species being represented on each page. In turning over the plates, a strong family-likeness to those of the early volumes of the *Botanical Magazine* is very evident; still, on comparing them, they are rarely, if ever, quite alike, though it seems probable that the same original drawing has often served for both series of plates. As an instance of what

FIG. 119.—CHRYSANthemum MRS. CHAS. BIRCH: PURE WHITE. (SEE P. 406)

plant-lovers will treasure"—if they can get it!—and I hope that our good friend W. B. Hemsley, of Kew, will at his leisure, tell us somewhat of its authorship and history. Sydenham T. Edwards, whose drawings are represented in its pages, as engraved on copper by S. nom, succeeded J. Sowerby, as the botanical artist of the *Botanical Magazine*, and his signature

Magazine. My own copy of *The New Flora Britannica* is a handsome large quarto, beautifully bound in crushed green morocco, with handsomely-embossed borders and rich gilt tooling. The edges are also richly gilt, and fine in colour—real old gold; not the thin yellow Dutch-metal now so common. The plates are bold and faithful in colour, two or three

I mean—one of many. If we turn to the plate of Strelitzia Regina, *Bot. Mag.*, t. 119 (dated May 1, 1790), and compare it with plate 53 of the 2nd volume of *Flora Britannica* (1812), we shall perceive that a leaf has been added behind the flower, and there are some minor modifications in the inflorescence itself; still, no one could doubt but

that the same original sketch had served for both plates, and we find this close resemblance, but rarely, if ever, an absolute likeness in many of the other plates in the book, as on plate 6. *Amaryllis formosissima*, the leaf of which is differently arranged as compared with *Bot. Mag.*, plate t. 47, and the colour of the flower is more crude and darker, or the crimson-red has become discoloured. This again is a striking feature, viz., that the colours of the *Flora Britannica* are not so pure and clear and lasting as those of the earlier volume of the *Bot. Mag.*; as an instance of this, compare plate *Bot. Mag.* t. 52 with that in *Flora Britannica*, xxvi. (*Gentiana acaulis*), the blue of the older plate, 1788, being far more pure and clear than that of 1812. This *Flora Britannica* may probably have been an outcome of Edwards' secession as artist of the *Bot. Mag.* It is curious that both Pritzel in his *Thesaurus Bot. Lit.*, and Daydon Jackson in his *Guide to the Literature of Botany*, both cite this *Flora Britannica* under Edwards' name as *New Botanic Garden*, although on the title pages of the work itself, *The New Flora Britannica* is clearly and unmistakably given. Is it possible that the same plates have been issued under that or some other similar title? I have seen a good many book and sale catalogues, but only once saw a copy cited, which was the one now in my library. The work is well printed on good sound paper, and as you observe in your note in *Gardeners' Chronicle*, p. 366, the text is singularly exact and trustworthy, although no author's name is given. Could it have been edited by Mr. J. Bellenden-Ker, or was it compiled by Edwards himself? These are queries upon which Mr. Hemsley may possibly be able to throw some light, and I hope that a note thereon may be added to the entry of this and other rare works in the forthcoming *Catalogue of the Lindley Library*, for the appearance of which we are anxiously waiting. *F. W. Burbidge.*

CHRYSANTHEMUM MRS. CHAS. BIRCH.

THIS new variety is a seedling raised by Mr. Godfrey at the Exmouth Nurseries. It is very distinct in general form, and in the shape and arrangement of the petals, the latter being almost entirely tubular, and not flattened or spatulate, and the curling is irregular, the result being a very solid bloom of great depth (see fig. 119, p. 405). The colour is usually pure white, but sometimes the base of bloom is shaded with lavender. Mrs. C. Birch was awarded a First-class Certificate by the National Chrysanthemum Society on Nov. 1, last.

Obituary.

HORACE BILLINGTON.—The death of Horace Billington (chief Curator at the Government Botanical Gardens at Old Calabar), news of which, from neuritis (?), has just been received at the Foreign Office, occasions a loss to the country, and certainly to the West African Protectorate, that it is difficult to estimate. He was the youngest son of the Rev. G. H. Billington, rector of Chisbury, Dorset, in which remote village he was brought up, acquiring that sympathy with Nature and the love of observation of plants, birds, and beasts which stood him in such good stead in the later years of his all too short life. Mr. Billington came to London about eleven years ago, and he not only entered the office of Mr. Thomas Christy, in the City, but resided at his house at Sydenham, where he had the opportunity of watching the propagation of the plants and seeds, and learnt especially the habits of different African products. When in the City he attended the sales, and watched the produce coming from abroad. By this means he was enabled to estimate the proper plan of packing and selection. In the course of time he was offered an appointment by the Royal Niger Co. Soon after his arrival the managers of the different estates found that they had in Horace Billington a man far above the ordinary level of trained assistants sent out to the colonies, and a competition sprang up between these men as to who should have his services, because the small estates entrusted to his care answered remarkably well. He took advantage of the information he had

received from planters and travellers, and when he arrived in face of the work, he knew what to do, and how to select his land; and instead of attempting to make the water run up hill in pipes, he found streams at higher levels, and conducted these through his plantations. Sir Claude MacDonald, who is well known for his thoroughness in all that he does, made enquiries, and found that there was at the Niger a man of the name of Billington; he traced out his connections in England, and obtained the promise of an interview as soon as he arrived home for his holiday. It was not long before he entered into arrangements through the Foreign Office with him to go out for the Government and open a botanical garden at Old Calabar. Mr. Billington knew exactly what was required, and although at home recruiting his health, he worked up his collection of books and also supplies of seeds, tools, and other requisites, so that when the time came for his return to the Niger he was able to open his garden and go to work at once.

It was unfortunate that the expenses were so critically examined that Mr. Billington was very cramped in his requirements for cash, otherwise he could have made many excursions into the interior and have obtained much more quickly the valuable information in his possession at the time of his death. It is also very unfortunate that a good man was not put with him to assist in detail in the trying climate of Old Calabar. Further, such a man would have learnt very much from Mr. Billington's experience, and the Government would have had some one now to rely upon to continue the valuable work started by Mr. Billington.

Another singular trait in Mr. Billington's character was the way in which he watched and chronicled information regarding health in the dangerous climate of the Niger. He said in his letters how much he regretted that the young men came out with unsuitable clothing—for instance, caps instead of pith or felt helmets, because no one had cautioned them as to their manner of living. When a bright sun was not shining, they believed that a cap was quite sufficient protection for the nape of the neck; the consequence was that they died one after another.

Mr. Billington, when in the service of the Royal Niger Co., was appointed to attend to the hospitals, to prevent the jealousy of the different estate-owners. This gave him an insight into the diseases which existed, and their mode of treatment.

At the time of Mr. Billington's last sojourn in this country, he arrived looking and feeling very ill; but the air which he found in his native village in Dorsetshire picked him up, and when he was about to return, his friends all congratulated him upon his robust appearance, while the official medical examination before returning was completely satisfactory.

Sir Claude MacDonald asked him on one occasion how he accounted for his healthy looks, when other people, on coming from the Niger, looked so sickly? He said that perhaps it was owing to his being so tall, his mouth being higher than that of others from the ground and that his abstemious habits, which he had practised from boyhood, had served him a good turn.

The brief telegram to the Government, announcing his death, furnishes no particulars. The last letters received from him said how well he was in health.

The reports made to the Government on the plants to be found in the Niger district surprise botanists in this country, for to each was allotted its value for commercial purposes or otherwise. This was a line that no other foreign botanical garden had ventured on. During his visit to this country he was able to set at rest many doubtful subjects of the source and origin of drugs, and the trees that yielded the supplies.

TRADE NOTICE.

We understand that Mr. J. H. Nieman, who was some years ago "decorator" at Mr. John Wills' establishment, South Kensington, has been appointed manager of the Floral and Horticultural Bureau, 371, Oxford Street, W.

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

NOVEMBER 23.—Present: Dr. M. T. MASTERS (in the chair); Mr. DOUGLAS, Rev. W. WILKS, and Rev. G. HENSLAW (Hon. Sec.).

Gall on Jasmine.—With reference to the specimen brought by the secretary to the last meeting, Mr. MacLachlan reports that it is quite impossible to fix on anything in particular in the way of a cause, but the puncture of a *Phytoptus* is the most probable.

Phyllotreta on Cruciferae.—He also observes, with regard to the beetles show by Mr. Michael as destructive to Stocks, &c., that "the genus is the one to which the 'Turnip-flies' belong. There are about a dozen species in this country, all being much alike. They all frequent the Cruciferae, and the fact that this one was also found on *Tropeolum* only intensifies the fact that most things which feed on the former will also feed on the latter, as—e.g., the larvae of 'Cabbage white,' the interpretation being that both contain the same chemical vegetable products."

Dahlia, Hybrid (?).—Flowers were received from R. J. Lowe, Esq., of Shirenewton (Hall, Cheshire, supposed to be the result of crossing a Dahlia with the pollen of a Sunflower. The appearance was that of a Dahlia, the disc alone being rather larger. Dr. Masters undertook to examine them more minutely.

Monstrous Cyripedium.—Mr. Veitch sent a plant of *C. sitius* bearing a single flower. It had no lip, but two columns. It was referred to Dr. Masters for further investigation.

The Copper-plant.—Dr. Masters exhibited an illustration of *Polycarpa spirostylis*, F. von Mueller. It has the above name, as it is said only to grow where copper is to be found, and that its presence is an indication to miners of the existence of that metal in the neighbourhood. It is found by the mines of Watsonville, &c., N. Queensland.

Proliferous Chrysanthemum.—A specimen bearing three flowers was received from B. Graeves, Esq., of Broome Hall, Dorking. They were remarkable for consisting of a dense mass of minute heads instead of distinct florets. Some of the show Dahlias, Dr. Masters observed, consisted of this peculiarity, the separate heads combining to make a single large "flower." The peculiarity is characteristic of the genus *Echinops*, only the individual heads contain but a single flower each.

DEVON AND EXETER GARDENERS.

NOVEMBER 24.—The subject treated of at this meeting was "Herbs: their Cultivation and Uses," the essayist being Mr. W. Andrews, gr. at Elmfield, Exeter.

After mentioning the ordinary pot-herbs that everyone is acquainted with, the old-fashioned medicinal herbs, such as Camomile and Peppermint, Horehound, Hyssop, Thyme, good as an ointment for gouty and sciatic pains, were alluded to, and their economic uses in the household, especially in rural districts, was enlarged upon. The lecturer pointed out the value of Borage, Marjoram, and Thyme as honey-yielding herbs that everyone who kept bees ought to grow largely. The lecture, of considerable length, was eminently practical and suggestive, and contained much useful information.

ELGIN CHRYSANTHEMUM.

NOVEMBER 24.—The second annual exhibition of Chrysanthemums, fruit, and vegetables, under the auspices of the Elgin Chrysanthemum Show Committee, was held on the above date. The arrangements were carried out in admirable order and efficiency by the energetic honorary Secretary, Mr. J. Thompson, assisted by a willing committee.

There were about 300 entries. A handsome Challenge Cup, valued at ten guineas, presented by Mr. Thompson, the Secretary, for eighteen Japanese blooms, brought some splendid collections, and the trophy was deservedly awarded to Mr. Barbour, gr. to Mr. GREGORY, Maryhill, who had an exceptionally fine collection, the blooms being marked for their freshness, colour, and size. Among the finest of them were Charles Davis, Mrs. E. W. Clarke, Van den Heede, and M. Chenon de Leché. The collection shown by Mr. McDONALD, Palmercross, came in a good 2nd.

In incurred blooms, the prize for the best was awarded to Mr. SMITH, Innes House, for a William Tunnington.

There were only two entries for wreaths, Mr. BEATTIE, florist, obtaining 1st prize.

There was a splendid display of hand and table bouquets of Chrysanthemums. In the amateur section, Mr. THOMPSON, Bishopmill, carried off the 1st prize for nine blooms in six varieties, one of them being "Hairy Wonder," and another a "Charles Davis," the latter gaining him also a prize for the best Japanese bloom shown in the amateur classes.

Mr. ROYAN, Fortes, was awarded the 1st place for his collection of incurred blooms. He showed a lovely bloom of "Jeanne de Arc," which won the prize for the best incurred among amateurs' exhibits.

A new feature was a competition confined to ladies for baskets of Chrysanthemums and foliage, and in the seven entries forward, there was a pretty and attractive display, the various baskets being arranged with great taste.

There was a good average display of pot plants, though these had not the attractive appearance of the cut flowers. The special prize for the best specimens was awarded to Mr. McDONALD, Palmercross.

Fruit and vegetables made a splendid show, the vegetables especially being greatly admired. In a class for a collection of vegetables, which attracted considerable notice, Mr. SMART, Leamurdie, carried off the Medal.

Mr. BEATTIE, florist, had a tastefully laid-out stand for exhibition only, containing some rare blooms of Chrysanthemums and Narcissus, as also numerous samples of Apples, including the Ecklinville and Lord Suffield.

Mr. W. WALLS, the Earlswood Nurseries, Ltd., also sent for exhibition a number of famous blooms; while Mr. WISEMAN, seedsman, kindly sent a number of Palms and other pot plants to decorate the hall.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

NOVEMBER 25.—Present: G. S. Ball, Esq., of Ashford, Wilmslow, in the chair; and Messrs. A. Warburton, Wm. Stevens, Geo. Law Schofield, S. Gratrix, J. Leemann, H. Greenfield, P. Weathers, R. Johnson, Wm. A. Gent, and Anderson.

There were seven Medals forthcoming that had been presented at a former meeting, together with a beautiful Medallion of the late Charles Darwin; and the Chairman, Mr. Ball, indicated that he meant to bear the expense of the die of the Silver Medal presented. The design is in every way appropriate, the name of the winner being on the obverse.

By far the larger number of plants brought before the committee were passed over; there were, however, three plants submitted which received First-class Certificates, viz., *Odontoglossum* × *Gratrixianum* (O. Halli × O. elegans), a combination of yellow and bronzy colours, which will improve under cultivation, and be regarded as a desirable acquisition. One of the others was a beautiful and a distinct seedling *Cypripedium* × *Veitchii* × *niveum*, a fine variety, with the characteristics of both parents, and showing the blending of the softer tints in an exquisite manner. The owner would do well to bring it before the committee when better established. It was shown without a name, but that omission will be amended in the Society's records. The third one, *Cypripedium* *insigne* *Sanderianum*, was in fine flower, the colours clear, without spots, and altogether uncommon. This came from Mr. GRATRIX.

Of Awards of Merit there were no fewer than twenty, which, taken in the order in which the plants were dealt with, were *Cypripedium* × *Minoes* × *C. Spicerianum* and *O. Arthurianum*, *C. insigne* Dorothy, of the *C. Sanders* type; a beautiful *C. x Beckwith* and *C. Boxall*, splendidly spotted, which will require another year to fully prove it; *C. Alliani* × *C. Spicerianum* and *C. Curtisii*; *C. x Ceres*, *C. hirsutissimum* and *Spicerianum*, a grand flower, which will improve in cultivation; and *C. nutans* *superbum*, a magnificent flower; *C. Belletianum* and *C. Fascinator*, as well as the pretty *C. Minoes*, were honoured with 2nd place. *C. Leeannum giganteum* was shown in fine style.

Cattleya labiata *Eugenie*, a beautiful, clean, clear coloured example, was similarly honoured.

The finest form ever seen of *Oncidium* *Forbesii* was shown by Mr. ANDERSON under the name of *O. F. splendidiolum*, which, in regard to colour and form, is unmatched, and well deserved the Award of Merit unanimously given.

Other plants were a seedling *Cattleya* from Mr. LEEMANN, called *Rosa*, and *Dendrobium splendidiolum grandiflorum*, with a pendulous raceme of grandly coloured blooms, equally in every point a flower of the spring.

These plants came mainly from members sitting as experts, although the strict rule of non-voting was observed by all those whose exhibits came up for an opinion.

Mr. J. ROSSON, nurseryman, Bowden, showed a varied group, and was awarded a Silver Medal for his pains. This is his first exhibit of importance, and it may be a means of inducing others to add their quota to future meetings of the North of England Orchid Society.

LEAMINGTON CHRYSANTHEMUM.

NOVEMBER 25.—The annual show of the Leamington, Warwick, and District Chrysanthemum Society, was held in the Winter Hall, Leamington, and was visited by large numbers of people.

The more attractive portion of the exhibits was shown in the Pump Room, including a beautiful display by Mr. F. PERKINS, of Leamington, who was awarded a special Silver Medal. Some of the designs in Chrysanthemums and other flowers were very artistic, and not only tasteful in form, but also in the arranging and blending of colour.

Mr. J. KITLEY, of the Castle Nurseries, Warwick, exhibited some of the choicest plants from his houses, many of them well-grown specimens; and other displays were made by honorary exhibitors, including Messrs. HINROW BROS. (Warwick), CLIBBAM & SONS (Manchester), and IRWIN & RAPER (Leamington).

The competition in the various classes was keen. In the open classes for Chrysanthemum plants, Mr. R. GREENFIELD, jun., of Leamington, swept the board with a collection of magnificent specimens. He obtained 1sts for single plants; three dissimilar varieties; a group arranged for effect; and a special for the best six plants.

Out blooms were in abundance, and the highest excellence was attained by many of the exhibitors. The competition for Mr. C. A. Smith Ryland's special prizes was close, and the premier award fell to Mr. ALBERT CHANDLER, of Cotton House, Rugby, who was followed in order of merit by Mr. R. GREENFIELD, jun.

Mr. SMITH-RYLAND himself won two 1sts for incurred blooms, and the 1st for blooms of the Japanese variety. Premier awards in other cut bloom classes were also secured by Messrs. A. CHANDLER, W. FRASER (Woodon), R. GREENFIELD, jun., and FINCH & CO. (Milverton).

A special prize given by Mr. W. M. Low, of Wellesbourne for the best collection of fruit, was secured by Mr. H. LIXBY, Wellesbourne House. Another special prize, by Messrs. Thomson and Sons, Clovenfords, for black Grapes, went to Mr. W. R. MANN, of Leamington. The table decorations, bouquets, and various other designs by lady amateurs were extremely tasteful.

In the fruit and vegetable classes, and the competitions for table devices, the merit was remarkably even. In the latter the first prize was secured by Messrs. FINCH and Co., who had a most elaborately adorned table. Second honours fell to Mr. W. VAUSE, Leamington. *Birmingham Daily Mail*.

DUNDEE CHRYSANTHEMUM CARNIVAL.

NOVEMBER 25.—This event took place in the Drill Hall, Dundee, on the above date, and a grand and imposing exhibition it was. The various competitions were well contested, the quality of the plants and flowers was good; never before has Dundee enjoyed so fine a spectacle as on this occasion. The president of the society is W. S. MELVILLE, Esq., the secretary W. P. LAIRD, and Mr. DAVID CROLL as treasurer. These able officials being assisted by an excellent executive committee. Everything passed off satisfactorily, and it is to be hoped that the financial results will afford encouragement for the future. The show was opened by Sir WILLIAM HARCOURT, who was accompanied by the Lord Provost and the members of the corporation. Sir WILLIAM HARCOURT, in a humorous speech, declared the show opened. The chief feature of the show was the competition for the Challenge Cup, which was of a very splendid character. The blooms shown in this contest were very fine and fresh looking.

CUT FLOWERS (OPEN TO ALL).

Thirty-six Blooms, Japanese, not fewer than four varieties, 1st (Challenge Cup, presented by Mr. J. M. White, Balrudery, and £3 10s.), James Beant, gr. to Mrs. GEORGE ARMISTEAD, Castle Huntly; 2nd, A. McDonald, gr. to Mrs. STEPHEN, Helenalea, Broughty Ferry.

Twenty-four Blooms, Japanese, not fewer than twelve varieties, 1st (Challenge Cup, presented by Mr. J. J. Watson, Ballinard), John Bell, gr. to ex-Sheriff ROBERTSON, Burnside, Forfar; 2nd, D. Nicoll, gr. to Mr. J. W. BELL, Rosie, Forganfield.

Six Vases Japanese Chrysanthemum Blooms, six varieties, three blooms of each, 1st (Challenge Cup, presented by Mr. J. M. Smeaton, Broughty Ferry, and 30s.), David Nicoll, gr. to Mr. J. W. BELL, Rosie; 2nd, D. KELLOR.

Six Vases Chrysanthemums, distinct (not disbudded), any foliage, 1st (flower-vases, presented by Mr. McBurney, china merchant, and 10s.), JAMES BEAT; 2nd, A. Duncan, gr. to Captain CLAYHILLS HENDERSON, Invergowrie.

OPEN TO AMATEURS ONLY.

Twelve Blooms, Japanese, not less than six varieties, 1st (Challenge Cup, presented by Mr. J. B. Lawson, and 12s.), EMIL DOWMERT, Monifeth; 2nd, JOHN CLARK, Southmartine Road.

Three Vases, Japanese Chrysanthemum Blooms, three varieties, three blooms of each, 1st, JAMES DAVIDSON; 2nd, WALKER MELVILLE.

PLANTS (OPEN).

Four Pots Chrysanthemums, disbudded, distinct, 1st, D. KELLOR; 2nd, JAMES JOES.

Best Japanese Bloom in Show (gardeners' class), Mr. D. NICOLL, Rosie.

Best Japanese Bloom in Show (amateurs), EMIL DOWMERT, Monifeth.

The six medals of the Society were awarded as follows:—Gold Medal for Chrysanthemums, NORMAN DAVIS, Framfield, Sussex; Gold Medal for Collection of Plants and Fruit, Messrs. JOHN LAING & SONS, Forest Hill, London; Gold Medal for Octagonal Group, Mr. WILLIAM COLOMBSTER, Ipswich; Silver Medal for Zonal Pelargonium, &c., Messrs. CANNELL & SONS, Swanley, Kent; Silver Medal for Collection of Chrysanthemums, Messrs. DOBBIE & CO., Rothesay.

The competition in the specimen-plant classes was disappointing, as was that in most of the fruit and vegetable classes, although those who were awarded the higher prizes showed produce of fine quality, and especially good were Grapes, Apples, and Pears.

Honorary exhibits were numerous, and those from the south were very creditable, Mr. NORMAN DAVIS, of Framfield Nursery, Sussex, showing a grand collection of cut flowers, similar to that which attracted so much attention at the National Chrysanthemum Society's Show at the Royal Aquarium.

Messrs. LAING & SONS, of Forest Hill, showed an interesting collection of miscellaneous plants, cut flowers, and hardy fruit.

The Isthemic Guano Company set up a fine group of plants.

Messrs. CANNELL & SONS exhibited cut blooms of some Pelargoniums, of new varieties of Cannas, and some fine bulbs of Onions.

Messrs. DOBBIE, of Rothesay, had a group of mixed plants, as well as a stand of cut flowers.

Messrs. G. BUNYARD & CO., Maldstone, showed a very fine collection of Apples, which met with a good deal of admiration from the visitors, and which was one of the chief features of the show.

Messrs. LAIRD & SINCLAIR, nurserymen, Dundee, contributed a good, interesting, and extensive group of hardy and greenhouse plants and cut flowers, the whole making a pleasing exhibit.

Messrs. D. CROLL & SONS, Messrs. HARLEY & SONS, and Messrs. STONRIE & STONRIE also contributed groups of a miscellaneous character, varied in style, and as regarded their composition. A. O.

ABERDEEN CHRYSANTHEMUM.

NOVEMBER 26, 27.—This newly-formed Society held an exhibition on the above dates in the Art Gallery, Aberdeen. The idea of instituting such an exhibition was first ventilated at the annual meeting of the Royal Horticultural Society of Aberdeen last year, but as the funds of that Society were not sufficient to render such a project practicable, the matter was dropped for the time being. However, as there was a general desire that an exhibition of the kind should be held, a number of gentlemen who had specially interested themselves in the matter shortly afterwards formed themselves into a society for the purpose.

The second exhibition of the Society showed a marked superiority over the one held last year. The quality was greatly superior, and the entries (400) were nearly double. The flowers shown by Mr. James GRANT, gr. to Lady CARRON, Crimonmogate, were specially meritorious, and he worthily carried off the prizes for the finest single Japanese incurred bloom, as well as the finest incurred in the show.

In the amateur section the specimens were very good, notably those shown by Mr. GEORGE STEPHEN, Cuparstone Lodge. The Chrysanthemums in pots attracted much attention by reason of their beauty of colour and grouping. A feature of the exhibition was the superb collection of fruits and vegetables.

The following are the names of the gentlemen who carried off the principal special prizes presented for competition:—Twenty-four Japanese, Mr. J. GRANT, Crimonmogate; twelve Japanese, Mr. FRASER, Craithes Castle; six Japanese, Mr. D. CHAPMAN, Aden House; twelve incurred Chrysanthemums, Mr. J. GRANT, Crimonmogate; twelve varieties of Chrysanthemums, not disbudded, Mr. MACDONALD, Balgowrie.

Considerable attention was devoted to several stands sent for exhibition only. Messrs. CANNELL & SONS, nurserymen, Swanley, Kent, had a beautiful display of winter-flowering Pelargoniums, and some Chrysanthemum novelties. Another notable collection was that from Messrs. SMITH & SONS, Aberdeen. Brilliant Chrysanthemum blooms were worked into wreaths, crosses, and other devices, resulting in a most dazzling display. There was also an exhibit from Mr. W. WALLS, Earlswood Nurseries, Surrey, showing numerous and beautiful specimens of the newest Chrysanthemums. Messrs. BEN REID & CO., Aberdeen, had a fine table of Conifers.

ROYAL BOTANIC.

NOVEMBER 27.—A meeting of the Fellows of the Royal Botanic Society was held on the above date in the Society's gardens at Bogen's Park, Dr. Boxall presiding. Lord Suffield, Lord John Cecil, and eight others were elected Fellows, and six were elected members. There are two nominations for Fellowship at the next meeting.

The Chairman observed that there were on exhibition in the gardens some very fine specimens of the *Cypripedium* *insigne*.

Mr. Sowerby, the Secretary, called attention to some Kola plants grown in the gardens, and said that the tree, which was a native of the West coast of Africa, between Sierra Leone and the Congo, belonged to the natural order Sterculiaceae. The seeds, several of which were contained in a fleshy fruit, 4 in. to 6 in. long, were the well-known Kola nuts of West Africa, where they had been used as far back as it was possible to trace. It was estimated that Kola paste is five times more sustaining than Cocoa; it contained over 2 per cent. of pure caffeine, and, compared with Tea, Coffee, and Cocoa, the Kola preparations were far more nutritious and did not create biliousness, as did Cocoa and Coffee, nor nervous excitability, as in the case of Tea, so that the problem of "What may we drink?" might probably be solved. A number of these plants were propagated at Kew in 1880, and distributed to Calcutta, Ceylon, Zanzibar, Demerara, Dominica, Sydney, Mauritius, Java, Singapore, and Toronto, where the Nuts were now produced. It had been reported from Jamaica that if a demand should arise for them in this country, the Nuts could be shipped thence to the extent of many tons per year. Notwithstanding its important properties, it is only lately that any great demand has arisen for the production. As medicinal agent, it is specially valuable as a powerful nerve-stimulant.

NATIONAL CHRYSANTHEMUM.

NOVEMBER 29.—A meeting of the Floral Committee took place at the Royal Aquarium on the above date, and though at the end of November, a few interesting flowers were staged.

First class Certificates of Merit were awarded to Japanese Mrs. J. R. Tranter, shown and raised from seed sent from America, by Mr. J. R. Tranter, Henley-on-Thames, a reflexed flower, having the build of Madame Carnot. The basal petals deep lilac pink, with a white centre; cut blooms, and a plant, the blooms above medium size, full, and symmetrical in shape, being exhibited; and to Japanese Violaceum, a flower very like Vivand Morel in colour (with perhaps more purple in it) and built, and not to be distinguished from some of the characters the former occasionally assumes—from Mr. E. BECKETT, Aldenham House, Elstree (First class Certificate), but only by a bare majority of the committee voting for the award.

Mr. WILLIAM WELLS, Earlswood, sent one or two market varieties—a somewhat vague term—one of them named Setting Sun, in the way of Golden Gate, but with more bronze in its colour; very bright and pleasing.

Two very pretty feathery-flowered varieties were Commended for late cutting purposes, viz., Sam Creswell, soft lilac pink, with pleasing feathery blossoms—very pretty; and Mrs. W. Butters, small white feathery petals—very attractive indeed, and very promising.

Mr. A. HAGGART, the Gardens, Moor Park, Ludlow, sent Moor Park, pale bright crimson, with golden-amber reverse, in the way of Col. W. B. Smith, but not large enough for show purposes as shown.

From Mr. G. W. FORBES, Regent House, Surbiton, came a number of seedling single-flowered varieties, all more or less coloured, which he stated he had raised from the single-flowered white variety Purity.

The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

DISTRICTS.	TEMPERATURE.					RAINFALL.		BRIGHT SUN.	
	ACCUMULATED.					No. of Rainy Days since January 3, 1897.	Total Fall since Jan. 3, 1897.	Percentage of possible Duration for the Week.	Percentage of possible Duration since Jan. 3, 1897.

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

SKELETON LEAVES.—Can one of the correspondents of the *Gardeners' Chronicle* kindly tell "Leirion" how to make skeleton leaves (Oak, Chestnut, &c.) so as to leave small devices, letters and figures still green and undisturbed on the network of veins.

NOTICES TO CORRESPONDENTS.

ARALIA VEITCHI: *Reader.* Graft on *A. Guilfoylei* in a close case, doing so either by approach or detached scion, the former, of course, the surer method in the hands of a novice.

ATACCIA VIRIDIS: *H. R.* If you sought *Ataccia* in the *Dictionary of Gardening*, you would not find all the species under that name, but some of them under *Tacca*—the Malay name. *A. or T. viridis* does not occur. The plants do well in a mixture of loam, peat, and sand, and being natives of Burmah, Malaya, Madagascar, and other warm regions, they must be cultivated in the stove. The plants require but little water when at rest. Propagation is by division of the roots.

BOOKS: *G. H. H. Vines' Students' Text-Book of Botany* (Swan, Sonnenschein: 1895); *Handbook of Systematic Botany* (Warming), edited by Prof. POTTER; same publishers. These are works of a general character. If you require books for a particular purpose, we will endeavour to assist you. —*Books.* No. 1. We are unacquainted with the one that you name. *My Gardener*, by H. W. Ward, is a very good work by a professional gardener, quite up to date. It is published by Eyre & Spottiswoode, East Harding Street, London, E.C. No. 2. This is one of the best of its kind, and a useful book. No. 3. Not sufficiently useful. *Nicholson's Encyclopedia of Gardening*, four vols., is a much more suitable present. It is published by Upcott Gill, 171, Strand, London, W.C.

CARNATION: *G. W.* The usual *Carnation fungus*, *Uredo dianthi*, for which we can suggest no effective remedy. All diseased plants should be burnt. *M. C. C.*

CARNATIONS: *W. L.* *Carnation-rust*, *Uredo Dianthi*.

CHRYSANTHEMUM SPORT: *C. G.* The bloom is an uncommonly weak one, but the colour bright and pretty. Give it careful culture next season. A bright yellow-flowered *Vivand Morel* should be valuable.

CROWN BUD IN CHRYSANTHEMUM PLANTS: *B. P.* What is meant by the "crown" bud was fully explained by cut and text in *Gardeners' Chronicle*, August 29, 1896, p. 249. The "first" break usually occurs between the middle of April and the end of June, and the accompanying bud is not "taken." The second, or "crown" bud, generally forms in August. This, however, must not be read as applying to "tops" struck late, and flowered in small pots.

CUCUMBER-HOUSE, 200 FEET LONG, AND 14 FEET WIDE: *W. J. B.* The wire-netting would, as you suggest, answer sufficiently well, provided you made it sloping, and nearly parallel to the roof, which is easily done by having the central row of posts taller than those at the sides. But we are not sure from your words that it is a trellis that you want, or merely something wherewith to confine the seeds (soil) at the sides of the bed. If the latter, the plan proposed would doubtless answer, but it would not be so good as a wall of boards—rough slabs, such as the sawyers take off in squaring timber; or of bricks, or concrete; the evaporation of moisture from the bed, and the consequent necessity of affording large quantities of water and manure-water to the soil at frequent intervals, being a constant source of expense. You are quite right in wanting to raise the Cucumber-plants up to the light; a 2 to 3 feet of stem is as long as it ought to be. You will find good varieties in Covent Garden Favourite, Cardiff Castle, Lockie's Perfection, Sion House, and Tender-and-True. Any nursery or seedsmen in a large way of business would furnish seed of the varieties named. We cannot recommend any particular house.

DISEASED PEARS: *R. F. W.* Too rotten to determine the variety. There is no apparent fungus, except what results from decay. From the decayed fruit the cause cannot be determined, as there is no apparent difference from ordinary rot. *M. C. C.*

DISFIGURED LEAVES OF ORCHIDS: *R. N. H.* Anything that gives a sudden check to growth, as cold draughts from ventilators or door, or the effect of cold on removal from the culture-house to some other place, impure air, or air impregnated with gas, &c.

GRAPES IN TOMATO-HOUSE: *W. J. B.* Owing to the length of time required to perfectly ripen Gros Colman Grapes, we could not advise you to plant this variety. Some early-ripening variety, like Black Hamburgh, Alicante, Alnwick Seedling; as white Grapes, you might successfully grow Chasselas Vibert, and Diamant, an oval Sweetwater, ripening without artificial heat; flesh firm, sweet, and pleasant eating. If you plant so many as four rows of Vines up the middle of the house, and one row in each side-bed, it is only a small part of the beds that will be available in a few years for Tomato culture; so that the two kinds of crops cannot go on for long in the same house. Better divide the house with a partition, cultivating Tomatos and Vines separately, and this, too, without waste of space.

NAMES OF FRUITS: *F. W.* Apples: 1, Hambledon Deux-ans; 2, Royal Russet.—*E. M. P.* Apple, Tibbett's Pearmain.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*J. A.* *Laelia anceps* *Sanderiana*, a close ally of *L. anceps Dawsoni*.—*J. B.* *Cymbidium Mastersii* and *Miltonia Clowesii*.—*T. D.* 1, *Retinopora squarrosa*; 2, *Echinops Ritro*.—*Japanica.* *Origanum majorana*, the common Marjoram.

PHAIUS: *A. G.* The black spots arise from any injury to the plant, or from the application of water at a lower temperature than that of the house.

RASPBERRIES FOR MARKETING: *W. T.* A list of varieties is given in our "Hardy Fruit Garden" (see p. 398, of the present issue).

RICHARDIA SPATHES COMING WITH GREEN STREAKS: *Reader.* Usually the result of extra vigour, induced by over-manuring at some period of the growth of the plants. When that is the case, the exhaustion of the soil in the pots will bring about improvement. You can do nothing now to prevent the green streaks appearing.

TOMATO-HOUSE 30 FEET WIDE: *W. J. B.* In order not to waste the area available for planting, the walks should not be more than 2½ feet wide, and if they are made to surround the central bed, this would give a width of 9 feet to that, and a bed on each side of 8 feet in width. If the plants are to be grown erect, with a single stem, they may be planted in rows 2 feet apart, running north by south, and 1½ foot apart in the rows. We have seen Tomato plants put out much closer than this that bore extraordinarily heavy crops of fruit. Of course, close attention must be paid to the removal of laterals, and that the growth be sturdy, yet excessive water should not be extravagantly afforded, and air should be given whenever the weather admits of it being done safely—night and day in the summer, and in sufficient volume to prevent drawing of the stems and foliage. Once a good crop is set, good pickings of ripe fruit are continuous in a large house, of 200 feet in length, such as yours, over several months. For winter fruiting, we should prefer more space between the plants—say in each direction 2½ feet.

TOMATOS: *W. J. B.* The best soil is the pasture loam of which your holding consists; but as the turves will not have decayed much by planting-time, the bed, although chiefly put together of these, should contain available plant-food in the form of garden-mould, or something like it, with some decayed stable-manure added to it. Good varieties of Tomatos for indoor cropping are *Frogmore Selected*, *Duke of York*, *Acme*, *Young's Eclipse*, and *Polegate*. These are early fruiters, and very prolific. We should suppose that the cheapest method of training would be to have sticks of Ash or Chestnut smaller than Hop-poles. Horizontal wires would be more economical in the end, but they would greatly interfere with the performance of the work among the plants.

THE Gardeners' Chronicle.

SATURDAY, DECEMBER 11, 1897.

THE GREENHOUSE IN THE WINTER.

WHAT a variety of conceptions arise in the mind in speaking of this familiar structure, and how few stop to consider that it is a very modern adjunct to the garden. Sixty years ago the greenhouse existed mostly in the gardens of the aristocracy and in botanic gardens. Public parks had them not, for the simple reason that, with the exception of the Royal parks, which boasted of no glass-houses, no others were in existence to which the public had admission at all times. The modern greenhouse came in with cheap locomotion, cheap glass, cheap wood, and iron, and with the general increase of comfort and the pleasures of life that followed on the introduction of free trade, and the remission of taxes after the great European wars of the early part of the century, with the introduction of steamships and railways, and what is understood by the word Progress. With the cheapening of glass, the old fashion of glazing with small panes of glass disappeared; greenhouses were no longer the half-lighted, leaky structures they had been, and it was now possible to cultivate plants in them with success; and the maintenance of a fairly uniform temperature was possible even in times of severe frost. This was formerly an impossibility, owing to the almost innumerable laps that allowed of the escape of the warmth of the interior from roof and sides. Similarly nearly all glass-houses were, for this reason, constructed as lean-to's, with sheds erected at the back, so as to minimise some of the evils of the necessarily faulty construction. An isolated glass-house was in former days almost unheard of. At about the time of the repeal of the duty on glass, hot water began to make its way as a means of heating, and many were the crude and unsatisfactory methods adopted before our present system of hot water heating was perfected. But before hot water, came hot air, "The Polmaise system." It must suffice to mention its name, for although it made a great stir in the world of horticulture early in the '40's, it really never had any great degree of popularity, and its adoption was limited to a few large gardens. The trade we believe never took it up seriously, and the few market gardeners who practised the little-known art of forcing flowers and fruits stuck with pertinacity to the simple method of heating by means of flues, as did the nurserymen.

By degrees we advanced slowly from the open hot-water trough, which was really a modification of the smoke-flue, and attached to either a fixed or free-standing small boiler by means of a

short length of lead or iron pipe. This method was not bad in its way, but it was extravagant in practice, as each pit or house had its special boiler, and the coal bill was increased accordingly. We recollect seeing a greenhouse in a nobleman's garden, near to, and now incorporated in London, which had an ordinary washing-copper sunk in the floor, and heated by a furnace fixed in the back wall; a couple of siphons connected this with the hot-water pipes. It afforded a handy supply of heated water for use in the greenhouse, and at times a good deal more humidity than the plants required; moreover, the air that got into the pipes, and accumulated at the bends stopped the circulation of the water, and it had to be removed by a specially-contrived air-pump. Gone are the old methods, and we have now as perfect a method of heating as we could desire, and instead of one house one furnace or boiler, we have boilers capable of warming at various degrees fifty to a hundred houses and pits, and needing merely a duplicate boiler attached to the main flow and return-pipes for use in case of very hard weather, or of the failure of one of them; and the necessary valves on the branch flow and return pipes. As with the structure and its heating apparatus, so with the plants grown therein.

The purely cold greenhouse with its stock of hard-wooded plants—the backbone of the contents—the Camellias, Orange and Shaddock trees, *Rhododendron arboreum*, Indian Azaleas, Acacias, Banksia (but few of these now), Polygalas, Myrtles, Eugénias, *Clianthus*, *Neriums*, and other plants, still find, as they deserve, a place in most gardens; but the structure is going, its place being taken by that modern invention, the show-house, conservatory or intermediate-house, as it is indifferently called. This change was inevitable from the immensely greater number of species now called into our service as compared with fifty years ago. Besides, we force a far larger number of species and varieties than we did then; and these plants, in order that they may continue to open their flowers for some time after coming out from the forcing-pit, require to be accommodated in houses furnished with rather more warmth than is desirable in the winter season for those plants above-mentioned, which are then mostly in a state of repose. The part of the year when the warm greenhouse is more particularly grateful is from the beginning of October onwards, as hitherto the temperature has been sufficiently high out-of-doors to render artificial heat scarcely a necessity, and cool and intermediate greenhouse are then interchangeable terms. After that date they are so no longer.

The Chrysanthemum in October becomes the season's flower, and retains its pre-eminence till the fading days of December, reigning, therefore, undisputed queen for two and a half months. Formerly, after the flush of the Chrysanthemums, and these solely consisting of incurved, Pompon, and reflexed varieties, most of which we retain to this day, there was little to enliven the glass-houses, if we except *Salvia splendens*, and the later *S. gesneriflora*, till the earlier Dutch bulbs came in. The Roman Hyacinth was either unknown, or did not exist. *Lilium longiflorum* var. *Harrisii* was not; *Freesia refracta alba* was not much known in gardens before 1878, the year it was Certificated by the Royal Horticultural Society; *Begonia* Mrs. Heal, *B. Adonis* (Veitch, 1887), *B. Gloire de Lorraine* were unheard of. True, we had *B. Froebelli* from Ecuador in 1872. *B. incana*, a species with panicles of small

white flowers, introduced in 1840; *B. incarnata* in 1822, *B. manicata* 1842, and *B. nitida*, one of the best of the winter-flowering species, introduced so long ago as 1777. These, with the garden hybrid, *B. Weltoniensis* (circa 1868), composed all that we had of winter-flowering species in gardens fifty years ago. How great has been the advance in *Begonias* since J. Veitch, J. Laing, Henderson, H. Cannell, Messrs. Sutton, those who are acquainted with modern horticulture know full well; still, the advance is not so marked in winter as summer flowers. *Narcissus* are made to yield their quota to the flowers of winter to an extent not dreamt of in our young days.

The common Lent-Lily, or Daffodil—*Narcissus Pseudo-Narcissus*—a variable plant, and truly indigenous, is one that may be grown in pots and boxes for flowering early, but a few dozen roots should suffice. The true double form of this species, once thought to be lost, and which was re-discovered by Mr. P. Barr, may be preferred by some, but it has less gracefulness than the type. This must not be confused with the common large-flowered double Daffodil, which is of much larger growth, and has great Rose-like blossoms, which botanically is *N. Telamonius plenus*, and not exactly fitted for indoors-gardening.

The *Triandrus* section of *Narcissus* afford some nice forcing varieties in the type in *N. incomparabilis*, *N. odoratus*, and *N. Macleai*. We do not mention the varieties of these, because they are too scarce and dear as yet to be used for forcing.

Narcissus Tazetta in variety, belonging to the *Parvi-coronate*, or small-cupped section, should be included among winter bulbs, especially *jonquilla*. *N. jonquilla*, the Jonquil or Rush Daffodil, should not be forgotten; and for other desirable species for forcing into bloom in the winter, we must ask our readers to consult the nurserymen's bulb-lists.

We can now hardly imagine the show-house without its tree Carnations; and yet how new they are, for there were but few varieties before 1880, and these were *Alegatière*, still accounted of some worth, sent out by C. Turner in 1877, *Empress of Germany* 1872, *Gueldres Rose* 1877, *Maiden's Blush* 1870, probably not grown at this date; *Miss Joliffe*, sent out by Masters in 1871, *Rose Perfection*, *The Queen*, *White Nun*, and a few more. How large a proportion of our present day tree Carnations are quite of recent origin! *Cinerarias*, in recent times, have greatly altered in character, having become of dwarfer stature, broader in the corymb, larger in the individual flowers, with richer and more intense colours, and scarcely recognisable as belonging to the same species as the lanky, small flowered specimens of fifty years ago, that gardeners gave names to and propagated from offsets. Now, the seed of the *Cineraria* can be obtained so true and so good in every way, that the finest varieties can be obtained with much less trouble than was once demanded in the culture of the plants. The only *Cinerarias* which we now distinguish by name are the double-flowered varieties; the earliest of which, in point of time, was *Duke of Cambridge*, sent out by C. Turner, about 1860.

Cyclamens are indispensable in late winter, and, unfortunately for other species, it is only the giganteum varieties of *C. persicum* that meet with the greatest favour, the earliest raised of which was Edmond's giganteum, which has given the name to the strain. This was certificated in 1870, and the next by the same raiser was *roseum compactum* in 1862,

since which time so great a number of *C. p. japonicum* have issued from various nurseries that the maintenance of the name has become a burden; and these, as in the case of the *Cinerea*, *Glaucina*, and *Streptocarpus*, will in time disappear. The *Amaryllis* furnish many beautiful varieties for the winter flora, the bulbs, with special kind of treatment, affording blooms in late January and onwards; and some, like *General Garfield* and *Exquisite*, which originated at the Holloway nurseries of Mr. B. S. Williams, are true winter bloomers. *Kalanchoe carnea*, a Crassulaceous plant, likely to become a favourite flower naturally at this season; it was first seen about ten years ago. *Lachenalias* are favourite winter subjects, good for planting in pots or baskets, through the sides of which they can be made to show their flowers and foliage. *L. Nelsoni* is one of the earliest to flower. And we must not forget *Primula sinensis fimbriata* in all its beautiful varieties of crimson, white, pink, red, light blue, or rather lavender, the spotted, and striped. The old double-flowered *Primula* still remains one of the best of its class.

Bouvardias are to be found in finer varieties than formerly; and the plants still form indispensable warm greenhouse subjects during late autumn and winter.

Manettia micans should be grown in the winter-flower house. It has a neat habit and pretty flowers; and the *Libonias* ought not to be forgotten, being also of neat compact growth, evergreen, and the flowers of a lively scarlet. The brightest of all flowers of comparatively recent introduction are the zonal *Pelargoniums*, the large brilliant coloured blossoms in magnificent trusses imparting a glow to the house to a degree not found in any other plant of the season if we except the Indian *Azaleas*. Our finest zonals go back but little more than twenty years; Pearson's *Lady Belper*, 1876; Constance Grosvenor (Fleming) is older, 1863; but the best of them are much more recent. These zonals are new creations, and our fathers knew them not—at least, in their present state of development.

On this occasion it remains for us to mention but the following as true winter subjects, or which may be forced into bloom at this season. The beautiful, if somewhat formal, *Camellia*, a plant that is relegated too much to the rear, considering its great merits and the ease with which it can be cultivated and flowered; early-flowering *Gladolus*, as *The Bride*, and *Colvillei*; and various hardwood plants, as *Epacris*, in variety, *Ericas*, like *Wilmoreana*, *E. hyemalis*, Indian *Azaleas*, *A. mollis*, *A. rustica*, and the Ghent varieties; *Rhododendron hybridum*, *Kalmias*; and among deciduous subjects, *Lilacs*, *Prunus triloba*, *Spiræa astilboides*, *S. japonica*, *S. confusa*, *Deutzia gracilis*, *Staphylea colchica*, &c.

NEW OR NOTEWORTHY PLANTS.

IPOMCEA PERRINGIANA, Dammer, nov. spec.

THIS new *Ipomoea* was introduced from the Cameroons by the late Johannes Braun, son of Alexander Braun, and a plant of it flowered the first time last summer in the Victoria-house of the Berlin Botanic Garden. It is a large climber, with slender stems, only one line in diameter, and covered with stellate hairs. The discoloured leaves are disposed at intervals of 4 to 5 inches, petiolate, broadly ovate, three to five lobed at the base, cuneate; the lobes are obtuse mucronate. Length of the petiole 2½ inches; the lamina is 4 to 5 inches long, 4½ to 6½ inches broad. The inflorescence is pedunculated, peduncle 6 inches long, cymose, bracts linear, deciduous, 1½ line

long, ½ to ¾ a line broad; pedicels ½ inch long thickened at the upper end, shining. Stems, leaves, and peduncle beset with stellate hairs. Of the obovate obtuse calyx leaves, the outer ones (4 lines long) only have some stellate hairs, the inner ones 5 lines long, 2½ lines broad, are glabrous. The violet-rosea hypocrateriform corolla is over 3 inches long; the corolla-tube is contracted at the base, red on the interior surface, 2 inches long, and ½ inch in diameter; the five-lobed limb is 2 inches in diameter, the lobes are roundish, somewhat crenate-toothed; the five inæquilong stamens are inserted in the corolla ½ inch over the base, which is here thickened. From the white, at the base, hairy filaments, one is 1 inch, one ½ inch long, the three others are still 2 lines shorter; anthers 2½ lines long, sagittate, white exteriors; disc very short, five-toothed; ovary conic, 1 line high; style filiform, 1 inch long; stigmata globular, confluent. The plant flowered from August till the middle of October. *U. D.*

COCHLIGDA STRICTA, Cogn., n. sp.*

We have seen this species at Liège, in the collection of M. De Laireesse, nurseryman, with whom it bloomed last August. It was sent from Columbia by M. Lehmann, mixed with *Odontoglossum cirrosum*, which its pseudo-bulbs much resemble. In its beautiful rose-coloured flowers it is analogous to *C. rosea*, but differs much, chiefly in the following particulars:—Its pseudo-bulbs, of a bronzy-green, are thicker, the angles obtuse, only becoming acute towards the summit; the leaves, still very imperfectly developed, seem narrower and sharper; the common peduncle instead of being curved, is stiff and erect; the flowers are rather smaller, and more attractive, quite erect, and distinct, with much longer pedicels; the sepals and petals are shorter, broader, and less pointed; the lateral ones attached between them at least for two-thirds of their length, and not merely near their base; the lip is more fully joined to the column, shorter and broader, less distinctly lobed, the terminal lobe broadly triangular-ovate and spreading, instead of being oblong and bent back. *A. Cogniaux.*

JAMES BATEMAN.

YOUR just tribute to the memory of the dear old horticultural enthusiast, the late Mr. Jas. Bateman, calls to my mind many pleasant remembrances of that remarkable man. I paid him a visit at his pretty home at Worthing in 1894, and although his garden there consisted principally of natural-looking rockeries, formed chiefly by his own hands, and in which were planted a great number of rare plants, the day seemed too short to admit of even a tithe of its interesting subjects being inspected, so much had their loving owner to say about each. Naturally, the subject of *Orchids* was touched upon, and on my saying that a brief note of his first attempts at *Orchid* importing, happening, as it did, at a very important period in *Orchid* culture, would be interesting to many, Mr. Bateman promised to send me some notes on the subject, and strangely enough I turned to his letter again just before I heard of his death.

As I had Mr. Bateman's authority to make what use I liked of his letter, I here give it:—"It has been a great pleasure to me to revive memories of my first experience in *Orchid* importing. About the beginning of 1882 I sent (with my father's permission)

* *Cochlidia stricta*, Cogn.—Pseudobulbis late ovatis, satia compressis, angulis superne acutis ceteris obtusis; foliis angustis, acutissimis; pedunculo communi erecto, stricto, gracili, fere usque ad basin laxo multifloro; bracteis tenuiter membranaceis, basi vaginantibus, deinde triangularibus, acuminiatis, arcte adpressis; floribus erectis, distinctis, longe pedicellatis, pedicellis strictis; sepalis æquilongis, carnosulis, obovatis, apice subtruncatis apiculatisque, dorsali erecto apice leviter recurvo, laterali patulis usque ad ½ inter se coalitis; petalis erectis, obovato-ellipticis, abrupte acutis, basi cum columna breviter coalitis, sepalis dorsali æquilongis; labello connato, patentissimo, sepalis lateraliibus satia brevioribus, late ovatis, acutis, leviter vel obscure trilobatis, disco basi tuberculis 2 crassis laterali valde compressis munito; columna breviuscula, fere usque ad apicem cum labello connata, clinandrio margine antice utrinque anguste undulato. Crescit in Columbia.

a man of the name of Colley to collect *Orchids* in Demerara. He was under the protection of the two great Liverpool merchants, Moss and Horsfall, on whom he was authorised to draw up to the extent of £200 or £300. Colley did his best, and found abundance of *Orchids*, i.e., of *Catasetum* and yellow-flowered *Oncidium*s, which then were not worth their freight. The only new plant worthy of cultivation was a species of *Rodriguezia* or *Burlingtonia*, with large white flowers, which flowered beautifully and then died. There is a beautiful white *Catasetum* in the Demerara woods, but Colley was not fortunate enough to meet with it; indeed, it has not been found until a very recent period. All this reads like a very poor speculation, but that was not the case. You have heard, no doubt, of *Oncidium Lanceanum*, which Lance discovered in Surinam, a year or two before Colley went to Demerara. He (Lance) only sent over two or three plants to England, which made *Orchid* collectors mad. It had never been found in Demerara, but Colley stumbled upon a solitary tree (about five days' sail up the Demerara river) covered from head to foot with this *Oncidium*. He immediately set to work and stripped the tree, determined not to give others the chance! Nor, so far as I know, has the species ever been found, before or since, in that colony. Any how, it retrieved the fortunes of my expedition, for when a large healthy cargo was known to have arrived, everyone (save the fortunate holder of Mr. Lance's specimens) were prepared to go down on their knees for a bit, offering their greatest treasures in exchange. In this way (without any money passing) I became possessed of bits of all the then-known species, which I cared to have.

"But for this unexpected 'find,' my expedition would have been a total loss and bitter vexation.

"We did not then know that good *Orchids* are, as a rule, very rarely met with on the beautiful, tidal, tropical rivers, but must be sought on the nearest mountains at an elevation of 3000 to 6000 feet.

"One treasure I should like to see again, viz. 'Cassaripe,' genuine, and compounded by the Indians from Cassava. It was delicious, and the half-a-dozen bottles which Colley brought lasted several years. You may buy stuff here by the same name, but it is mainly made up of treacle."

From this interesting letter we get a glimpse of the enthusiast as he was in his declining days, but still retaining his fine intellect, and that pleasant way of putting things, which formed a great feature in his lectures at the Royal Horticultural Society.

With regard to *Oncidium Lanceanum*, it may be said that Mr. Jemman and others have since found it in British Guiana. I am pleased to be able to add, that through the kindness of Everard F. Im Thurn, Esq., of British Guiana, I was enabled to forward the wished-for supply of genuine *Cassaripe*, which gave great satisfaction. *James O'Brien.*

PLANT NOTES.

PINGUICULA CAUDATA.

DURING the month of November this beautiful Mexican species was to be seen in fine character in Mr. James Cypher's nursery, Queen's Road, Cheltenham. Quite a large batch of plants was observed in 8½-inch pots, blooming freely. One blossom at the termination of each long scape; in colour bright deep rosy-carmine or crimson. The leaves are formed in dense rosettes, long, narrowish, and of a pale yellowish-green colour. An individual plant produces a large number of flowers, thrown well above the foliage, and they appear to be somewhat lasting in character. So attractive are they from their peculiar colour, that they at once attract attention on entering the house.

P. caudata, which is a greenhouse evergreen perennial, is potted into a compost of peat, sand, and sphagnum moss in equal parts; the potting process is lightly done, the time of potting is after the plants have bloomed and been rested for a period, during which they require little water. As soon as they begin to show signs of growth they require more water, and then comes the time to divide. They do well in a temperature suitable for cool *Orchids*—about 45° to

50° by night during winter, and it is necessary there be plenty of moisture in the atmosphere both winter and summer. In addition to increasing by division, plants can also be raised from leaves (similar to the *Gloxinia*), and they are found to strike freely in the same compost as that recommended for growing plants. Plants can also be raised from seeds. Could a batch of the finely-grown and bloomed plants seen at Cheltenham have been sent up to one of the meetings of the Royal Horticultural Society during the autumn, they would have been certain to have aroused a great deal of interest. The species was introduced from Mexico in 1881. *R. D.*

TREES AND SHRUBS.

CASTANOPSIS CHRYSOPHYLLA.

IN December, 1882, a notice of *Castanopsis chrysophylla*, planted at Tortworth, was sent to the *Gard. Chron.* Since that date, the tree then alluded to has grown considerably. As it is far from common (fig. 120), and as it is sometimes supposed to be not hardy, a description of its present condition may be of interest to some of your readers. This plant was procured from Messrs. Veitch about 1854—56. On applying lately to them for a precise date, they were

and many healthy plants have been reared in spite of a considerable mortality during the first three years after germination. Several healthy specimens over 6 feet high have been planted out in the neighbourhood of the parent tree, or have been distributed among friends. One of these in the grounds of Sir Joseph Hooker at Sunningdale is now 10 feet high.

The experience of forty years has shown that *Castanea chrysophylla* is hardy here. It stands on a hill-side of old red sandstone on a southern slope of sand and loam, sheltered from the north and east by rising ground, and protected against the prevailing south-west wind by a grove of larger trees.

FIG. 120.—*CASTANOPSIS CHRYSOPHYLLA*—HARDY TREE: FLOWERS AND FRUITS.

(From a specimen sent by the Earl of Ducie.)

CYCAS REVOLUTA.

At Northdown House there is a large plant of *Cycas revoluta* bearing a cone. The same plant some eight or ten years ago produced a cone. It may not be unusual for the *Cycas* to bear fruit, but there are many who have never had an opportunity of seeing one, and to those it might be of interest to know that the plant produces a large tuft; the one I am referring to measures 46 inches round and 28 inches over, in the centre of the crown of leaves surmounting the stem. This tuft consists of woolly, pinnately-cleft leaves, studded with red fruits about the size of small nuts on either side of the edges, which are in the notches. The exact age of this plant is not known, but I should imagine it is quite forty years old. *H. Markham, Northdown, Margate.*

unable to trace it; they think, however, that their collector, Lobb, may have sent its seeds to them about 1853. In the winter of 1879 it was 20 feet high, with a girth of 17 inches at 3 feet from the ground. At the present moment it is 27 feet high, with a girth of 36½ inches at 3 feet from the ground. The increase in diameter at this point is, therefore, about one-third of an inch annually. The first branch is at 6 feet from the ground. The tree is in perfect health, and seems to be free from all insect enemies. Up to 1882 it bore sterile "burs," miniatures of those of *Castanea vesca*; but since that date it has produced good seed. About half a pint of these small Chestnuts, each no bigger than a small Pea, has been collected every autumn,

Before the publication of vol. ix. of *The North American Sylva*, by Professor Sargent in 1896, the references to this tree in botanical works were meagre and incomplete. Professor Sargent describes it as follows:—"A tree from 100 to 150 feet in height, with a massive trunk from 5 to 10 feet in diameter, and frequently free of branches for 80 feet above-ground. . . . A small tree in Oregon and on the Californian sierras, and usually shrubby at high elevations and on the Californian coast ranges south of the Bay of San Francisco. The Golden leaved Chestnut attains its greatest size and beauty in the humid climate of the coast valleys of Northern California, where, scattered among coniferous trees, it is one of the noblest and most beautiful inhabitants of the

forest, with its fluted columnar trunk and brilliant leaves, bright green and lustrous on the upper surface, and golden-yellow on the lower."

This golden-yellow colour on the lower-side of the leaves becomes very conspicuous when the branches are moved by the wind. Although the Tortworth specimen is never likely to attain the size recorded by Professor Sargent, its present healthy condition and uninterrupted growth seem to promise a tree of the fourth or fifth magnitude in the course of the next half-century.

In his description of the genus, Professor Sargent writes:—"Of *Castanopsis*, which is intermediate in its character between the Oak and the Chestnut, about twenty-five species are now recognised; one inhabits the forests of Pacific North America, and the others South Eastern Asia, where they are distributed from Southern China through Malaya to the Eastern Himalayas." In all the species the leaves are persistent. It is a pleasure to me to have found a record of Dr. Asa Gray having examined my tree when on a visit here, January 11, 1881. *Ducie, Tortworth, Gloucestershire, November 12.*

COTONEASTER PANNOSA.

In the October number of the *Journal de la Société Nationale d'Horticulture*, M. Maxime Cornu is reported to have shown before the Society a specimen of this shrub, discovered by the Abbé Delavay in Yunnan. The leaves are small, and covered on the under-surface with a whitish down; whilst the berries are globose, of the size of Peas, and produce a good decorative effect.

ORCHID NOTES AND GLEANINGS.

LÆLIA PUMILA PRÆSTANS.

SOME collections of Orchids have been embellished during the past season with the best varieties of *Lælia pumila* hitherto observed, which are of recent importation. The name "præstans" is generally admitted to be untenable as that of a species, though the original form of *L. pumila* described as *L. præstans* had some distinct features which are well set forth by Messrs. Veitch in their *Manual of Orchidaceous Plants*: "Lip trumpet-shaped and not straight as in the type, convolute side-lobes overlapping at the margin, very stiff in texture, so that they cannot be spread out without splitting; lines of the disc almost obsolete, disc orange-yellow." A flower exactly answering to this description, and differing from the bulk of *L. pumila* observed in gardens, is sent by G. F. Moore, Esq., Bourton-on-the-Water.

LÆLIA × JUVENILIS (PERRINII × PUMILA).

All of the hybrids of *Lælia Perrinii* are desirable on account of their showy flowers, appearing chiefly in the autumn and winter; and in the present instance, the beauty of the flower is enhanced by its being produced on a neat, compact-growing plant. A good example is sent by Messrs. J. Charlesworth & Co., Heaton, Bradford, with the remark that they regard it as one of the handsomest dwarf hybrid *Lælias* flowering at this season. The flower, which is about 5½ inches in width, has bright purplish-rose coloured sepals and petals, which are silvery-white at the base. The lip is bluish-white at the base, and maroon-purple in front, the margin being slightly crimped.

CYPRIPEDIUM GODEFROYÆ LEUCOCYLUM.

A good variety of this rare *Cypripedium* was illustrated from the collection of E. I. Measures, Esq., in the *Gardeners' Chronicle*, June 30, 1894, the flower having a cream-white ground colour, heavily blotched with purple, its general appearance being nearer to *C. bellatulum* than to *C. Godefroyæ*, from both of which it is distinguished by its unspotted lip. A handsome and novel form is now sent by G. F. Moore, Esq., Chardwar, Bourton-on-the-Water, in which the ground colour of the flower is pale yellow. It is a very large flower, and the heavy claret-purple markings contrast strikingly with the large labellum, which is unspotted on the exterior, but beautifully marked with purple dots inside.

ODONTOGLOSSUM DUVIVIERIANUM ×.

This remarkable and pretty natural hybrid, which is generally regarded as the progeny of *O. nebulosum* and *O. maculatum*, was first flowered by M. De Smet-Duvivier, Ghent, who sent it to Reichenbach in 1888. In his description, the Professor sums up by remarking, "It is a beauty;" and the expression regarding it has doubtless been often repeated by others—not that it is so showy as some of the other *Odontoglossums*, but it is pretty in form, and novel in colouring. The ground of the flower is white, as in *O. nebulosum*, which it much resembles in the form of the lip; the sepals and petals have a lemon-yellow tinge, and bright cinnamon-brown blotches on the inner halves. The lip is white, with cinnamon-brown base and marginal spots. It was well figured in the *Lindensia*, v. p. 55, and a plant is now in flower with Messrs. J. Charlesworth & Co., Heaton, Bradford, Yorks.

LÆLIA RUBESCENS, syn. L. ACUMINATA.

This is a plant of small growth, not much seen in collections, although at this season its flowers are very attractive. It is said to be somewhat scarce in Mexico and Guatemala, from which it was introduced in 1840. The pseudo-bulbs are ovoid, and have a shining appearance, with a short leathery leaf at the apex. The flowers are borne on slender scapes about 1 foot long, which spring from the apex of the pseudo-bulb. At Edinburgh the flowers are almost white, with a blotch of maroon colour in the throat of the lip. The colour of the sepals and petals is said to vary. The plant does best under Cattleya-house conditions. *R. L. H.*

DISEASE IN JAPANESE LILIES.

"LOVERS of the beautiful Japan Lily have, probably, been alarmed by the news that its existence was threatened by a novel and destructive disease, a description of which is given in the current number of the *Kew Bulletin*. Fortunately, however, says an Exchange, with the account of the bane, comes the discovery of an antidote.

"The disease appears to have developed with astonishing rapidity. It was practically unknown two years ago; but the crop of bulbs raised last year in Japan for exportation to Europe was almost

entirely ruined by it. The attention of the authorities at Kew was drawn to the matter by a London firm, who forwarded to them, for examination, a large number of the diseased bulbs. Out of 73,000 bulbs of *Lilium speciosum* sent to them from Japan, only 250 were fit for sale when they arrived in England. Nor was this all, for out of a consignment of *Lilium auratum* received at a later date, amounting to nearly 40,000, only about one-tenth was unspoiled. The disease is a peculiar form of fungus. The experts have found that short immersion in a 1 per cent. solution of corrosive sublimate, or of salicylic acid, is fatal to *Rhizopus necans*, as this pest is called. The growers of these beautiful flowers in Japan will do well to abandon the infected grounds, and to adopt this simple precaution. From the 'Daily Advertiser,' Yokohama, Japan."

My attention having been drawn to the above cited article, I should like to say a few words regarding this fungus, *Rhizopus necans*, based simply on experiments and experiences gone through during the time that I have been connected with the firm of L. Boehmer & Co. in Yokohama, the oldest nursery firm as exporters of Japan Lilies in this country. It has happened not only lately, but as long as Lily bulbs have been exported, that the results have been sometimes very disheartening for the consignees as well as for the shippers, but of losses like those in the article above referred to I have never heard. I imagine that the great loss is probably the result of some Japanese or other speculators, who, in order to obtain the best prices, have shipped the bulbs at the wrong season.

The climate of Japan is such, that during and after the hot and sultry summer months—July, August, and September, during which we have a temperature of from 85° to 95° Fahr., the rainy season sets in, which produces a real hothouse temperature, the air being saturated with moisture, which is splendid for growing, but not for harvesting field products. The moisture is so great that not only out-of-door things get affected by fungus formations, but even in our houses clothes, boots, shoes, &c., in short, everything which is not in daily use becomes covered with mould.

It is, therefore, easily imaginable that during such a season, bulbs taken out of the field not perfectly ripened, packed into boxes, shipped through the tropics to Europe, may be affected by fungus formations which have, during a two months' voyage on board a steamer, sometimes close to the boilers or some heat-producing cargo, sufficient time to do their deadly work. The danger would not be so great if the bulbs could be brought direct from the fields into the boxes. This seems, however, impossible. Even with the greatest care, with such tender articles, a few bruises, and a little injury to their scales are unavoidable. These generally favour the growth of the fungus formations, which very soon take hold of the whole bulb. After this sultry weather, the autumn season sets in during October, with fine, dry days, warm during day-time, but brisk and refreshing during the night.

The earth gets dried, and the season for harvesting arrives. The Lily bulbs are now perfectly ripe, in a dormant state, and in a proper stage for export. The weather being then dry and cool, any bruises the bulbs may receive during the handling will dry off and heal quickly and satisfactorily. There are also a few very tender varieties, which even the most careful treatment will not protect against the hardships of a long voyage through such different climates as the route by India, the Red Sea, and the Suez Canal offer.

I recommend the following remedy:—1st, place your order with some respectable firm, which knows its business; 2nd, do not give instructions, if possible, regarding the time for shipment, but leave this to the shippers, who will know the best time the bulbs are ripe, and the best time for packing and shipping; 3rd, try to induce the steamship owners on the Eastern lines to provide a few steamers during the principal export season with cold storage arrangements, to get the shipments through the trials of change of climate. *A. Unger (L. Boehmer & Co.), 5 and 28, Bluff, Yokohama.*

NÆGELIA AMABILIS.

SOME short time since, Mr. P. Blair, of Trentham, exhibited a fine batch of these plants at the Royal Horticultural Society, from one of which our illustration (fig. 121) was taken. The plant was originally

in April and May, in a temperature of 65°. When the pots are filled with roots, shift them into 5 and 6-inch pots, in a compost of loam, leaf-mould, and sand, in equal parts; a little peat may also be added. After the plants get well established, have them put into an intermediate-house; shade from the sun, and

FIG. 121.—NÆGELIA AMABILIS: FLOWERS CREAMY-WHITE.
(Reduced One-half.)

figured by Decaisne in the *Flore des Serres*, xii, p. 21 (1857), and afterwards in the *Bot. Mag.*, t. 5088, under the name *N. multiflora*. The plants lately exhibited were so beautiful, and so well cultivated, that we asked Mr. Blair to furnish us with some particulars, which he has had the kindness to do:—

"The corms are started in batches in 3-inch pots

air freely on fine days, but avoid draughts. When the flower-spikes appear, a little stimulant can be given; they commence to bloom early in September, and continue until the end of November, many of the plants carrying from twenty to thirty spikes of flower. After flowering is over, they can be stored away in a warm dry place until started again in spring. P. B."

BERLIN.

ENGLISH PRIMULA SINENSIS FIMBRIATA AT BERLIN.

It may be an interesting fact to the readers of the *Gardeners' Chronicle* to learn that the large-flowered varieties of *Primula sinensis fimbriata* are finding their way more and more into the Berlin nurseries. They fetch prices three to four times higher than the common German varieties, viz., 6s. to 7s. 6d. the dozen, against 1s. 6d. to 2s. 6d. Mr. Kretschmann, Pankow, Berlin, is a specialist in Primulas, who raises yearly 300,000 to 500,000 seedlings, and he says, that still the demand is greater than he can meet. It is quite true that these fine varieties are as easily cultivated as the common ones, and they will in time oust them out of cultivation. Contrariwise to the English fashion, these large-flowered varieties have no names, they are only designated by terms, as white, large white, red, rose, blue, &c. Dr. Dammer, Gross Lichterfelde, Berlin.

ANANAS NERVOSA MAXIMA.

This is a Pine-apple of enormous size, and very fine flavour. At a recent meeting of the Berlin Horticultural Society, Herr Gartenbau-director Hampel Koppitz exhibited a fruit which had a weight of 4 kilogrammes 125 grammes, or a little more than 9 lb.

CHRYSANTHEMUMS AT BERLIN.

On the occasion of the last meeting of the Berlin Horticultural Society, Herr Garten-inspector Weber, Spindlersfeld, Berlin, exhibited a collection of twenty-

FIG. 122.—FLOWER OF NÆGELIA AMABILIS.
(Natural Size.)

six Chrysanthemums, which showed that the cultivation of these plants is now well understood at Berlin. The finest variety was the white Tangarita, seeds of which were imported directly from Japan by Hofmarschall von Saint-Paul. This is indeed a very noble flower, of fine build, and of the purest white. I am astonished not to find this variety amongst those exhibited at the National Chrysanthemum Society's Show in the Royal Aquarium. Certainly it is a variety that would make its way in England. Medium-sized flowers are 8 inches in diameter, but some of the flowers exceed 9 inches. It would be interesting to learn of what dimensions this variety could be grown by English specialists. The other varieties which Mr. Weber exhibited are well known in England, a good many having been exhibited at the Royal Aquarium. The varieties were—Le Colosse grenoblois, Hairy Wonder, Melusine, Beauty of Truro, M. Ch. Molin, James Bidscope, Directeur Tisserand, Madame Carnot, Arona, Australian Gold, Th. Denis, Charles H. Curtis, Mrs. H. Kloss, Le Dac, Bellem, Niveum, Waban, John Seward, Sonne von Blankenburg (a very fine golden-yellow, very large variety), George W. Childs, Good Gracious, F. W. McHattie, Hallow E'en, John Machar, Mrs. H. Weeks. Only two of these reached the dimensions of Tangarita, namely, Sonne von Blankenburg and Hallow E'en. Dr. Dammer, Gross Lichterfelde, Berlin.

wadding, over which these pests can seldom pass. In consequence of the need of increased artificial heat in the warmer divisions, the voracious cockroach will become more troublesome. After cleaning the houses, and the plants are put straight, it will be necessary to remove any accumulation of rubbish from under the stages, empty pots, &c., or these insects will avail themselves of the protection afforded. All dry corners in the houses should be kept thoroughly moist, as in such places they congregate and multiply. Cockroaches are particularly fond of the roots of *Aërides*, *Vandas*, *Saccolabium*, *Phalenopsis*, *Lælia*, *Cattleyas*, also the young leaves of some *Dendrobiums*; therefore these particular species should be examined with more than ordinary vigilance. Make use of beetle poisons, of which two or three excellent kinds are to be obtained; but it is not advisable to lay down the same kind of poison on each consecutive night, but occasionally to substitute one kind for another.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, late of Eastnor Castle, Ledbury.

The Fig-house.—The trees, if started early last month, will now be pushing their buds, and should be afforded a slightly higher degree of warmth, say, 55° at night, with a corresponding increase by day. If the Fig-trees are grown in pots or tubs, let the heat of the bed they are plunged in be kept steady at 78°, adding prepared fermenting leaves and stable-litter if the heat be declining. As the buds develop, the amount of the syringing may be lessened. The state of the soil as regards moisture must have close attention, enough being afforded to the trees in pots and borders as will maintain healthy growth; the borders, more especially, if made of proper materials, taking large quantities of water. Any neglect in this particular will be very apt to cause the young Figs to drop off at a later date. The water employed should be of 80° to 85° of warmth.

Intermediate and Late-houses.—In the succession Fig-house pruning and clearing should now be finished. The chief points to be observed in pruning are to remove all of the weakest shoots, the injured or immature points, and to reserve only such shoots as possess strong, well-ripened points, and when securing the trees to the trellis, to take care that these bearing shoots are evenly distributed, otherwise much foliage will appear in some places and only bare patches in others. Keep the late Fig-house cool, short of admitting frost, and do not let the borders get excessively dry, which is apt to occur when a border is shallow or small, for although the Fig when resting requires to be kept dryer than any other kind of fruit, dryness should not be carried to extremes. Should any tree be making very gross shoots, if it be a young one, dig up the roots carefully, and replant it in the same or another place, first looking to the drainage of the border and ascertaining that no means of escape for the roots exist, as these will get through the smallest crack, causing a lot of trouble in remedying the mischief caused by roots obtaining access to rich soil beyond the border. Let the drainage materials be topped with turves, grassy side downwards, on which place some of the compost, consisting of friable loam three-quarters, and one-quarter of old mortar, brick-bats, or pieces of sandstone. Having placed the tree in its right position, proceed to spread out the roots in a suitable manner, at two or three different levels, covering them up as the work proceeds, and when the hole is filled, afford a mulch of long litter, and in a few days a moderate amount of water to settle the whole. In the case of old trees, which it would scarcely be advisable to treat in the above described manner, simple root-pruning must be resorted to, proceeding in the usual manner of root-pruning at some distance from the stem, and working towards it as close as may be advisable, and if possible cutting through all downward trending roots under the centre of the tree. Having laid all the roots bare up to a certain point, shorten the stronger ones and those that are damaged, and replant in new compost, and mulch and afford water as in the other case. No manure should be mixed in the soil; but the trees should receive liquid-manure when carrying heavy crops, the chief difficulty with young trees being to check the strong wood that is usually produced.

PLANTS UNDER GLASS.

By G. H. MAVOOCK, Gardener, Luton Hoe Park, Luton.

Hippeastrums.—Where early flowering is desirable, a number of bulbs may now be started, a selection being made of the best matured ones, that is those

that have been rested for the longest period of time. The temperature to which the bulbs may be subjected may range from 50° by night to 55° by day, which will be found suitable for the first month. The bulbs should be lightly syringed once daily in the forenoon, and but little water afforded the soil before the flower-scape commences to grow. Bottom-heat of 75° will help the growth considerably, but it is not essential.

Cyclamens.—Much care is demanded in affording water to these plants, especially in moist weather, and rather more warmth is required than that of the cold greenhouse. The pots should be stood upon a layer of fine gravel or spar, and if this be covered with wood-moss it will have a nice effect. If hot-water pipes exist under the staging, some amount of damping of the gravel and moss will be necessary at times, the moss serving the purpose of maintaining moisture-laden air about the plants, which is very favourable to their well-being.

Bouvardias.—Some of the earliest to flower having now ceased to be of decorative value, may be removed from the flower-house, being replaced with others of the same genus, or with diverse subjects. The *Bouvardias* that are removed should be kept rather dry at the root for ten days, and at the expiration of that time they may have the shoots that have flowered cut back for two-thirds of their length, and be fumigated or vapourised should aphides be present on the shoots, which is almost sure to be the case.

General Work.—Any plants of herbaceous *Calceolarias* that still remain in 60's should be re-potted into pots of 5 or 6 inches in diameter, and then removed from the pit or frame in which they may hitherto have been standing to a greenhouse. Green-fly being very apt to infest these plants, a sharp outlook must be kept for them, as it is impossible to kill the insects if present in large numbers on the crinkled undersides of the hairy leaves. *Brugmansias sanguinea* should be removed to some little-used greenhouse, and be cut hard back when the soil at the roots has become dry. This applies to plants in tubs and pots, but those that are growing in the borders of the conservatory being probably still green and fresh-looking, may wait a little longer before they are similarly pruned. Although I have named *sanguinea*, the single and double-flowered white *Brugmansias* require the same kind of treatment.

Lilium longiflorum Harrisii.—The first batch of these bulbs will be benefited by weak doses of farm-yard manure-water, and by being frequently fumigated. When any of the roots appear at the surface, as will generally occur, a top-dressing should be afforded of loam, peat, and rotten manure in a lumpy, rough condition, and any later surfacing may be done with common wood-moss. Any plants of *Eucharis* which may be passing out of bloom should be sponged and cleaned and placed in a house having a temperature at night of 65° till they cease to grow, supplying them occasionally with liquid-manure for a period of about six weeks.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Pruning Standard, Pyramid, and Bush Trees of Apples and Pears.—Upon the manner in which this simple though important operation is carried out depends almost entirely the building up of fruitful, and consequently profitable specimens, whether they be standards, pyramids, bushes, or espaliers. However, it would be better to let the trees go unpruned than to trust an unskilful man with the pruning—that is, to allow a man having no clear object in view in operating on young, or maiden trees. The formation of large fruit-bearing trees, of whatever kind, in as short a time as possible, is the wish of all who possess fruit-trees; therefore, the young leading shoots of standard, pyramid trees and bushes should be pruned back to within from 5 to 9 inches, each of these pruned-back shoots will produce from three to five growths next spring. These—assuming that we have last year's cut-back maiden-trees to deal with now—where likely to become crowded, or to cross each other in growth, should be cut back to within 2 inches of last year's wood; cutting back the leading shoots to from 18 inches to 20 inches of last year's growth. This will result in the formation of fruit-buds, in addition to promoting a symmetrical shape in the individual trees. Once young trees of this description have borne a fair crop of fruit, they will require very little annual pruning beyond the cutting out of a branch here and there where likely to cross each other, repeating the operation more or less every year as may be called for, until the trees acquire the desired size.

Pruning and Cleaning Established Orchard-trees.—Where the trees have become crowded together in the orchard, and but little, if any, pruning has been carried out, they are very apt to be coated with moss or lichen, more especially in humid localities; and a severe thinning-out of the branches and of the worst of the trees is the only remedy for this state of things. The branches that cross each other, or which are too abundant, should be removed entirely, in order to let the air and light into the crown. When the prunings are faggoted and removed, scrape the moss and lichen off the worst affected main-stems and branches within easy reach, with a bevelled strip of board or a strong label, and then syringe the entire crown with a wash made with fresh lime and a few handfuls of fresh soot and water, the liquid being passed through a fine-meshed sieve before using it, and choose a calm day for doing the work. A garden-engine is preferable to an ordinary syringe, especially for applying the wash to full-sized trees. This dressing will not only effectually rid the trees of the parasitic growths, but it will also destroy any larvae that may be in the moss. Hundreds of thousands of fruit trees are ruined annually in this country that by the exercise of timely attention in the direction mentioned above, might be rendered fruitful and remunerative.

THE APIARY.

By EXPERT.

The Feeding of Bees.—Then there is another argument against feeding back (see p. 327 ante), which is that, from some reason or other, this fed back honey is far more likely to become hard or to candy in the comb than is that which is put in the comb at the time it is gathered from the fields. When first taken from the hives it looks very nice and attractive, but when cool weather comes on in the autumn, it assumes a dull, unattractive appearance, showing that the honey has hardened in the cells, while comb-honey produced in the ordinary way is still liquid, and will keep so far from one to three months after the fed-back article has become almost unsaleable.

Combs of Honey for next Season.—Question: I have on my hives about 200 combs very full of honey, which I wish to use for next year's increase. I am at a loss to know what to do, so ask if it would be advisable to throw the honey out with the extractor and use the empty combs, or would it be best to use the full combs of honey? I expect to make my increase by natural swarming.

Answer.—If extracted honey brings a good price in your market, and the honey in the 200 combs is of good quality, then my advice would be to extract the honey and sell it, for the old saying "A bird in hand is worth two in the bush," is generally correct. If, on the other hand, extracted honey drags heavily at a price hardly above the cost of production, or the honey in the combs is of a quality not fit for the market, then I would store the combs of honey away till spring (allowing the bees to protect them till there was no fear of damage from the larvae of the wax moth), when I would use these combs for building up colonies in the spring, by exchanging them with the colonies for combs, that they might have which were empty or nearly so. In this way, you will get this honey converted into brood, which brood, when hatched it to bees, will store for you large quantities of honey. If the colonies in the spring had no need for this honey, then I would use the combs of honey something as you suppose, hiving new swarms on them. If the combs are only from one-third to one-half full of honey, then you may procure the best results by hiving your swarms on the full number of frames, and putting the sections on at the time of hiving. But if completely full from bottom to top, it will be better to use only from four to six combs to the hive when hiving the swarms, for if given a full hive of full combs of honey, the bees may not carry much of the honey to the sections, as they generally will do with the whole where only a few are used. If the bees do not immediately start to carrying the honey from these full combs, the result will be little or no honey in the sections, and little brood and few bees in the hive in the fall. But should the honey in the 200 combs be of inferior quality, or of dark colour, or both, then the only thing to do with it is to extract, or use it for spring feeding, for if such inferior honey is given at swarming time, more or less of it will find its way into the sections, thus injuring the sale of the honey, and giving yourself a bad reputation. "Gleanings" (American).

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, Dec. 14 { Royal Horticultural Society's Committee.
Annual Meeting of the National Dahlia Society, at the Hotel Windsor, at 2 P.M.

PROVINCES.—December 9 (6 P.M.): Max., 48°; Scilly; Min., 35°; Aberdeen.

Weather stormy, mild; light frosts.

In the year 1855, Dr. HOOKER, as he then was, published in conjunction with the late Dr. THOMSON, the first and only volume of the *Flora Indica*. This was but a fragment, though a magnificent one. The introductory essay is a most important contribution to botanical geography, and to the history of botany in India, whilst the notes represent the highest level of botanical morphology at that period. The plan was too vast to be carried out as it was begun, and so, to the great loss of British science, it was abandoned. But the idea of producing a complete *Flora of British India* was not lost sight of, and seventeen years after, the first part of the *Flora of British India* appeared.

With the issue of the twenty-third and twenty-fourth parts containing the index, this *Flora* has now been brought to a close. The first part was issued in 1872. The work thus has taken a quarter of a century to complete. In the earlier years of this period Sir JOSEPH HOOKER was laden heavily with official functions as Director of the Royal Gardens, Kew, together with endless duties arising out of his distinguished position as a traveller, a naturalist, and a botanist. At this time, therefore, the author availed himself of the co-operation of various botanists, and utilised the joint work of himself and Dr. THOMAS THOMSON as published in the fragmentary *Flora Indica*, or in various monographs published in the

Journal of the Linnean Society. Released from the cares of the Royal Gardens, and his labours lightened by the completion of the *Genera Plantarum*, Sir JOSEPH set himself to work with his customary energy to complete the *Flora of British India*. In this task he had the assistance of Mr. C. B. CLARKE, Dr. STAFF, and the members of the Kew staff; but when all allowance is made for material help thus afforded, the amount of original investigation and research, and the mass of literature dealt with and assessed by Sir JOSEPH HOOKER alone, can only be called prodigious. Horticulturists in particular have reason to be grateful for his elaboration of the Orchids of India—itsself a remarkable effort.

During the twenty-five years that have elapsed between the beginning and the end of this book, great changes have taken place. Not only have the collections of plants and literary material been augmented, but British India itself has largely extended her borders. Hence it comes that the later volumes are more complete than the earlier ones. At any rate, we have now a solid and substantial basis for any work that may be hereafter undertaken. From the whole extent of the Himalayas to Ceylon, from Beluchistan to Birma and the Malay peninsula, we have now a descriptive census of plants as complete as it is possible to make it—a work of the utmost value to botanists, and one as honourable to its author as it is a subject of pride to his countrymen. Taking into account the work done at Calcutta by Dr. KING and his assistants, the results of which are published by the government, that effected in the north-west by WATT and DUTHIE, by RIDLEY and CURTIS at Singapore, and by many others, we need not fear comparison with any other country in this matter at least.

The two parts just issued comprise the index to the seven volumes, this index alone occupying 417 pages in double columns! It is satisfactory to know that this index has been collated with the *Index Kewensis*, and that in consequence there will be less room for confusion of nomenclature and difference of usage.

ALBERTA MAGNA was raised from seeds sent to Kew in the summer of 1889 by Mr. MEDLEY WOOD, Curator of the Botanic Gardens at Durban, Natal. It is now an erect woody shrub 4 feet high with evergreen leaves like those of the common Laurel, and terminal panicles, 6 inches long and wide, of bright crimson tubular flowers. This plant has been in flower fully three months, and it is now ripening seeds. A larger plant, 7 feet high, was grown in the winter garden, but it died after being transplanted into the new Mexican-house, where the plant under notice now is. Smaller plants have flowered in pots in the Cape-house, from one of which the figure in the *Botanical Magazine*, t. 7454, was prepared. Mr. BULL included *Alberta magna* among his new plants offered in 1891. The first account in this country of this shrub was published in the *Gardeners' Chronicle* in December, 1888, p. 741. Our illustration (fig. 123) taken from a specimen obligingly forwarded from Kew, does not show the "accrecent" calyx, which it will be remembered occurs in *Mussaenda* and other near allies of *Alberta*.

ROYAL HORTICULTURAL SOCIETY.—The last meeting this year of the Royal Horticultural Society will take place next Tuesday, the 14th inst., in the Drill Hall, James Street, Westminster, when the Fruit, Floral, and Orchid Committees will meet as usual at 12 o'clock. A lecture on "Sporting in *Chrysanthemums*" will be given at 3 o'clock by the Rev. GEO. HENSLOW, M.A., &c.

OUR ALMANAC.—According to previous practice, we shall issue a *Gardeners' Chronicle Almanac* with our first issue in the New Year. In order to make it as useful as possible for reference, we shall be obliged if Secretaries of Horticultural, Botanical and allied Societies, or any of our correspondents, will send us immediate intimation of all fixtures for 1898.

LINNEAN SOCIETY.—At the evening meeting to be held on Thursday, December 16, at 8 P.M., the following papers will be read: 1, "On the Affinities of the Madreporian Genus *Alveopora*," by Mr. H. M. BERNARD, M.A., F.L.S.; 2, "On West-Indian Characeae collected by Mr. T. B. BLOW, F.L.S.," by Messrs. H. and J. GROVES, F.L.S., &c.

"BOTANICAL MAGAZINE."—The December number closes the fifty-third volume of the third series, or the 122nd of the whole work. The volume is dedicated to Mr. A. B. FREEMAN-MITFORD, C.B., the historian of the hardy Bamboos. The plants figured are:—

Agave Schottii, Engelmann, t. 7567.—A species resembling *A. filifera* in having fibrous edges to the leaves, but it has a lax one-sided inflorescence bearing numerous yellow flowers, each about 2 inches long.

Quillaja saponaria, Molina, t. 7568.—An interesting plant furnishing the Quillaya-bark used instead of soap. The specimen figured flowered in Mr. HAYBURY's garden at La Mortola.

Odontoglossum retusum, Lindley, t. 7569.—A species with panicles of orange-scarlet flowers. It is a native of Peru. The specimen figured came from the garden of E. H. WOODALL, Esq., Scarborough.

Kniphofia breviflora, Harvey, t. 7570 (by error 7571).—One of the smallest of known species, with bright yellow flowers. It is a native of Natal. Kew.

Habermaria rhodochela, Hance, t. 7571 (by error 7570).—A Chinese terrestrial Orchid with small green, hooded sepals and petals, and a relatively large four-lobed scarlet lip with a long spur at the base. Kew.

PRESENTATION TO MR. F. Q. LANE, J.P.—At the annual meeting at the King's Arms Hotel, on Saturday, of the Berkhamsted Chrysanthemum Society, of which Mr. F. Q. LANE is the Vice-president, and Earl BROWNLOW the President, Mr. Lane (of The Nurseries) was presented with a silver cigar-box, bearing the inscription: "Presented by the Committee of the Berkhamsted Chrysanthemum Society, 1886-1897," on one lid, and on the other "F. Q. L." Mr. A. Prudames, M.R.C.V.S., made the presentation. Mr. Lane, who was taken by surprise, expressed his thanks for the kindness shown him.

MUSHROOM CULTURE.—M. CH. RÉPIN contributes to the *Revue Générale des Sciences* for September 15 a long paper on the cultivation of the Mushroom in the underground quarries of Paris, and points out the obscurities which still exist as to the mode of nutrition of these fungi. He speaks of the desire of growers to obtain pure Mushroom-spawn, and of their difficulties in this respect. It is now said that by collecting on paper the ripened spores as they fall, Mushrooms of the desired kind can be raised on any nutritive material, such as is used in bacteriology, though not so easily or abundantly as can the inferior sorts. The dung is arranged in layers of equal thickness between overlapping plates of steel, and the whole is subjected to heavy pressure of about 50 kilos. to the square centimetre. When released from this, the dung is found compacted into blocks about a centimetre thick, nearly as hard as wood, and consequently easily handled. These blocks are seeded, then placed under conditions the most favourable to the development of the spawn, care being specially taken to avoid any rise in temperature. The growth of the spawn is thus retarded, but its vigour and activity, when transported to the warm atmosphere of the Mushroom-caves, is surprisingly accentuated. When the blocks of soil are thoroughly stocked by the spawn, they are cut into bricks 8 centimetres (3 inches) long. This operation

FIG. 123.—ALBERTA MAGNA: GREENHOUSE SHRUB. LEAVES EVERGREEN; FLOWERS CRIMSON.
(SEE P. 416.)

is effected very rapidly by means of a special cutting-machine. This compensates for the extra hand-work necessitated in making the blocks, and the final result is a more economic and convenient product to use than the spawn-bricks of the Mushroom-growers. It is needless to revert to the beneficial influence this innovation cannot fail to exercise on the Mushroom industry. Not merely is the problem of re-stocking with pure spawn—a problem always recurring—now solved once for all, but the Mushroom-grower henceforth can choose the variety which will best succeed in his beds, this being as the spawn exactly preserves the smallest morphological and physiological peculiarities of the original kind. Finally, this spawn is exempt from disease, a consideration which is also of value.

THE BEET-SUGAR INDUSTRY.—Many years have passed since Mr. DUNCAN, of Mincing Lane, London, proved, by extensive and exhaustive experiment in the vicinity of St. Albans, that the Beet-Sugar industry was not suited to our agriculturists. Possibly, experiments made since then have given better results: we would gladly notice them—the subject being one of interest to us all. The industry, as practised on the Continent, constantly interests, not only dwellers at home, but very many of our colonial friends. That the crop is of considerable value to bounty-paid growers in Germany, France, &c., may be gleaned from the following figures, collected by the Statistical Association for the Beet Sugar Interest at Magdeburg, who quite recently published the following comparative statement: "The amount of crop for the current year is estimated at 1,790,000 tons, as against 1,821,000 for last year; Austria-Hungary, this year, 922,000 tons; last year, 927,000 tons; France, this year, 751,000 tons, as against 703,400 in 1896." It will be seen that there is an estimated decline of nearly 90,000 tons; the actual turn-out may alter and improve these figures. Continental agriculturists would seem to be of the class "specially favoured," for not only is their Beet crop protected by an export premium, but the farm crops of other countries are handicapped by import duties.

CHRYSANTHEMUM CULTURE.—After admiring the magnificent specimens lately exhibited, many a gardener and many an amateur will be disposed to try his hand at the cultivation of the autumn Queen. He will find his trouble lightened by the perusal of an excellent little book just issued by Mr. GEORGE GARNER under the title *Modern Chrysanthemum Culture for the Million*, and published by BLAKE & MACKENZIE of Liverpool. We cordially recommend the little work, as the directions given are simple and trustworthy. We notice the buds are said to be "secured" instead of taken. Perhaps selected would be better still. A list of some of the best flowers in each section is given, with the treatment appropriate to each.

CHRYSANTHEMUM AFSNÉ.—This is a new white Japanese variety, raised at Afsné, the country residence of M. FRIESENS, the secretary of the Royal Society of Agriculture and Botany at Ghent. The plant is of dwarf habit, producing ivory-white flowers 6 to 7 inches across, and is figured in the current number of the *Revue de l'Horticulture Belge*.

THE COMMERCIAL USES OF COAL-GAS.—We have already incidentally alluded to this little book by Mr. THOMAS FLETCHER, and published by FLETCHER, RUSSELL & Co., of Warrington, but do so again on account of the practical importance of the subject. The reader will find just the information he requires as to the economical and efficient use of gas for various purposes, and within a hundred pages will find details for which he might have otherwise to wade through many volumes.

A HYBRID DOMBEYA.—Our excellent confrère, M. ED. ANDRÉ, describes and figures in the *Revue Horticole* a hybrid out of *Dombeya Masteraii*, Bot. Mag., t. 5639, by pollen of *D. Wallichii*, better known as *Astrapea Wallichii*, a fine plant, rarely seen outside of botanic gardens. The hybrid

flowered in the garden of the Botanic Garden at Lisbon, where it was raised by M. CAYEUX, hence the name *Dombeya Cayeuxii* ×, given to it by M. ANDRÉ. It has large cordate, dentate leaves, and large trusses of rose-pink flowers, each about 30 mill. across. It is hardy at Lisbon, and may probably prove so along the Riviera. In this country it would form a noble inmate of a warm conservatory.

HYBRIDS.—M. MARTIN CAHUZAC has sent to the editor of the *Semaine Horticole* six flowers said to be the result of a cross between a *Chrysanthemum* and a *Dahlia*. The evidence of hybridisation does not appear to have been very marked. A week or two ago, Mr. E. J. LOWE sent us flowers of a cross between a *Sunflower* and a *Dahlia*; the flowers were those of a *Dahlia*, but the central disc was proportionately larger and deeper. Improbable as such crosses appear, it would be rash to assert that they are not possible. Very often the application of the foreign pollen seems to induce enhanced growth of the seedling without actual change of form having taken place.

HYBRID BETWEEN A PHEASANT AND A BLACK GROUSE.—Mr. HARTING exhibited at a recent meeting of the Linnean Society a bird from Shropshire, precisely resembling a similar hybrid figured in early editions of *White's Selborne*.

PRODUCE OF WHEAT, BARLEY, AND OATS.—Preliminary statement showing the estimated total produce and yield per acre of Wheat, Barley, and Oats in Great Britain in the year 1897, with comparative statements for the year 1896, and for the average of the ten years 1887-96:—

Board of Agriculture, 4, Whitehall Place, S.W.
December 4, 1897.

PORTUGUESE FLORA.—The last issued part of the *Boletim da Sociedade Broteriana*, edited by Professor HENRIQUEZ, contains an article in French by M. J. DAVEAU, on the littoral flora of Portugal. The district north of the Tagus corresponds roughly to the region of *Pinus maritima* (Pinaster), and of deciduous Oaks; that to the south of Tagus answers to the *Pinus Pineas*, and of Evergreen Oaks. The former has many relations to the flora of North-western Europe; the latter is distinguished

by the number of endemic species, the frequency of Iberian forms, and the appearance of Algerian and Moroccan types. Mediterranean species are the most numerous, but not everywhere predominant. Each of the two great districts divided by the Tagus has its littoral, its region of the plains, its mountainous and its sub-alpine regions. In the present communication, M. DAVEAU treats solely of the littoral region. The "littoral land" possesses no analogy with the littoral flora of North Europe, and possesses a special local and Iberian flora.

THE COPPER PLANT.—Mr. S. B. SKETCHY in the *Geological Survey of Queensland* gives a description in a figure (tab. xviii.) of a *Caryophyllaceae* plant, which is, it is said, always associated with copper lodes. The plant in question is *Polycarpea spirostylis* of FERN. v. MÜLLER, and it occurs all over the copper region of Queensland, but always on or close to the copper deposits, or along watercourses charged with copper in solution. So abundant and so characteristic is it, that the presence of the copper is readily detected by the miner from an inspection of the plant. The Government analyst, Mr. BROWNIE HENDERSON, has analysed the plant and its ashes, and has discovered in them distinct traces of copper. The quantity found is larger than a mere accidental absorption would account for. Some birds it is known contain in their feathers a red pigment known as turacin, and which contains as much as five per cent. of copper.

ROSA BERBERIDIFOLIA.—Some years since the flowering of this plant with the Rev. Mr. EWBANK afforded us the opportunity, thanks to the kindness of that gentleman, of studying the peculiarities of this plant. Some writers consider it so different from a Rose that they place it in another genus; but we observe that M. PAUL PARMENTIER, in the *Comptes Rendus of the Bulletin of the Royal Botanical Society of Belgium*, 1897, p. 25, relying on anatomical data, shows that this plant has all the distinguishing characteristics of the genus *Rosa*:—"The structure of the petiole is practically the same as that of *Rosa*, and, according to MASTERS, these stipules exist in a latent state, or rather, the petiole has potentially the faculty of developing them under the influence of suitable cultivation." He quotes, in support of this theory, *Fraxinus*, *Fragaria*, and *Gleditsia*, which, under cultivation, bear 1-foliate leaves. M. PARMENTIER does not believe that such a transformation could ever be induced in a leaf of *Rosa*, or that *R. berberidifolia*, with composite leaves, could be produced. Pallas' Rose is a plant from arid desert soil, which has acquired great structural fixity, and which has lost the power of varying just because it has lived for a considerable time under conditions very different from the usual surroundings of vegetation, and themselves varying but little. It has admirably adapted itself to this unusual position; the transpiratory functions are in abeyance, the assimilatory power increased. The lateral leaflets have disappeared, and only the terminal one is a real leaf; the stomata, in compensation, are developed on the upper epidermis, but in sinking their ostiole in this epidermis at the same time, all the layers of the mesophyll are transformed into palisade cells. For figures, see *Gardeners' Chronicle*, July 20, 1889, p. 78.

THE NEW FLORA BRITANNICA.—The discovery in the Lindley Library of this volume (see ante, p. 405) has served to reveal the fact that the same book was published under different titles, and at different dates. In our last issue, Mr. BENNETT-PONS narrated how he got his first stimulus from this book; and we now learn that the title of this particular edition is the *Complete Dictionary of Practical Gardening*, by ALEX. MACDONALD, original drawings by SYDENHAM EDWARDS. It is in two volumes, and contains sixty coloured plates, and bears date 1807. The total number of flowers figured is 134.

NATIONAL CARNATION AND PICOTEE SOCIETY.—The annual general meeting of the above Societies will be held in the Room of the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, on Wednesday, December 15, at 7 P.M.

DUCHESS D'ANGOULÊME PEAR.

The finest and heaviest specimen of Duchesse d'Angoulême Pear that I had hitherto seen came my notice a short time ago. The fruit, one of four growing on a young tree on a wall in a south-west aspect (see fig. 124), measured round near the top, $7\frac{1}{2}$ inches near the base, 5 inches in circumference lengthwise, and the scale at $1\frac{1}{2}$ lb. This handsome fruit was coloured and of fine flavour. It was grown in the gardens of Stradey Castle, Llanelli, by Mr. T. an old pupil of the writer's, who has made improvements in the gardens during the six or seven years that he has had the management of the gardens. Mr. Lucas writes in reference to the specimen fruit: "I am proud to think have grown the finest specimen of the Duchesse d'Angoulême Pear that has come under your notice, by the one in question was the heaviest of forty-four fruits gathered from the tree; twelve fruits weighed nearly $1\frac{1}{2}$ lb. each, and the rest was a trifle over $\frac{1}{2}$ lb. I must tell you that it did not bear a single fruit in 1896, neither did the tree of Marie Louise on the same wall have any. Consequently, last autumn I dug out a trench each tree, and thoroughly root-pruned both and filled the trenches with a mixture of good and lime-rubble in the proportion of four parts former to one of the latter; making due allowance for the soil settling down a few inches in as many finishing off with a top-dressing of manure and a application of water at the time, and as often could do so during the summer and early autumn, with the result that the foliage of both trees most black in summer as compared with that of Pear-trees on the same wall—so much so that when visiting the gardens observed the difference. I gathered more than 2 bushels of excellent fruit from the Marie Louise, the fruits being clean and clear in the skin, of extra size, and of fine flavour. There are several trees of Duchesse d'Angoulême Pear in these gardens besides the one in question, and I have treated all of them this autumn in the manner indicated."

It is curious to seeing the Stradey Castle specimen of Duchesse d'Angoulême Pear, the finest examples of this variety which had come under my notice were (not for competition), at the Bournemouth and the Horticultural Society's autumn show, by the late Mr. Hitchcock, who is himself a keen pomologist. The size, evenness, and high quality of the specimens exhibited were commented on in the pages of the show published in the *Gardeners' Chronicle* at the time. I enclose a photograph of the Stradey Castle tree in fruit, and Mr. Lucas examining it. H. W. Ward, Rayleigh, Essex. [The heaviest fruit of this variety of which we have any note is $1\frac{1}{2}$ lb. 10 oz. See *Gardeners' Chronicle*, Oct. 1, 1897. It was grown by Mr. Symons, Carclew. ED.]

NOTES ON NEW CHRYSANTHEMUMS.

Sooner has the last of the exhibitions been held, and cultivators are engaged in the revision of the varieties to be cultivated for the succeeding season. Exhibitors know well the advantages to be gained by the inclusion in their collections of new varieties that are improvements upon older ones. For instance, the two white-flowered varieties, Madame Carnot and Avalanche. The former is quite a new white-flowered variety up to date, and the latter a half-a-dozen years ago occupied a similar position. Madame Carnot grows quite as large again as Avalanche, and in all other qualities it is superior to the latter variety. The disadvantage an exhibitor suffers from did he not cultivate Madame Carnot is therefore obvious.

For any readers of the *Gardeners' Chronicle* who have had opportunities to see for themselves the novelties, I purpose referring to some of the noteworthy that have come under my notice. It cannot be said that the season now closing has been very prolific in new varieties of sufficient merit to place them in the front rank at once.

The Japanese varieties being most popular with the public, as well as with cultivators, for the reason that they are so useful for decoration, I will allude to them first.

White-flowered varieties are usually regarded with high favour when they possess the necessary points of size, coupled with other items that go to make a perfect bloom.

Simplicity, although not absolutely new, was seen but little last year, and may therefore be classed as such. It is a full sized, well "built" bloom, of purest white, with somewhat narrow florets slightly flattened at the tips. Cultivators should not "take" too early a bud, or the florets become too tubular to present the best effect.

Madame Louise Reney is a pure white sport from the well-known Mrs. C. H. Payne. Those who are pleased with extra large blooms should grow this new variety. It is the exact counterpart of its parent in every way except colour.

FIG. 124.—A FRUITFUL TREE OF DUCHESS D'ANGOULÊME PEAR, AT STRADEY CASTLE.

Mrs. J. Lewis was sent out by Calvat last year or early in last spring, and is one of the best of modern introductions. The blooms are massive, the florets broad, and not too stiffly or loosely disposed. The purity of the blooms in colour, too, is especially noteworthy. It has a fine dwarf habit of growth, excellent blooms being obtained from plants 4 feet high.

M. Philippe Rivoire is best described as a much-improved *Souvenir d'une Petite Amie*, itself one of the finest varieties to grow for decoration—say, twelve blooms on a plant.

Mrs. Weeks, one of last year's introduction, has maintained its reputation as being one of the best of incurved Japanese varieties. No collection is perfect without this sterling novelty.

Lady Byron is another that has stood a severe test during the season just past.

Western King is a pure white, compact, ball-like blossom, praised by all who see it.

Mrs. C. Blick has given many substantial, highly-prized blooms of the purest white, and all cultivators are recommended to add this to their collection.

Mrs. Ritson.—*Vivian Morel* has at last given a pure white-flowered sport, the exact counterpart of its parent. *Mrs. Ritson* has, therefore, undoubtedly fine qualities.

Emily Silbury is, as the raiser claimed it to be, one of the best of white-flowered varieties; a trifle early, perhaps, but if this be so, it is the only fault that can be urged against it.

Snowdon much resembles *Avalanche* in its florets and general character, but grows to a larger size, and is in every way desirable.

Yellow-flowered varieties are generally more numerous than any other type. But few novelties of merit even of this colour are to be found this year.

Mrs. W. Mease, a primrose sport from the popular *Madame Carnot*, and *G. J. Warren*, a pure yellow-flowering sport from the same variety, originated last season, are quite the best, and, along with the parent, form a pleasing trio.

Royal Sovereign belongs to the incurved class of Japanese, in colour a rich orange-yellow.

Oceana, one of last season's introductions, will hold its own amongst pale yellow varieties in the incurving section.

Ellis Curtis, bronze-yellow, reminds one of *Boule d'Or*, so popular ten years ago.

George Foster is an English-raised seedling with irregularly incurving florets; pure yellow.

President Nonin, amongst apricot-yellow-flowered varieties, deserves attention.

Admiral Ito should commend itself to those who favour the erect petalled varieties; the florets are twisted much at the points.

Lovely is an American seedling of the palest yellow; the incurving florets make a full solid bloom.

Vicar of Elthorne is another bronzy-yellow-flowered variety, well worthy of attention; and equally so is *Mrs. C. Keyser*, which reminds one of the old Criterion style.

C. W. Richardson was sent out last year with a good flourish, which it has well sustained, the long, drooping, curling florets giving to the flowers a distinctive character.

Coloured varieties are more numerous, and need considerable selection.

Mary Molyneux is an incurved Japanese of large size and pleasing colour, being rosy-peach, with a silver suffusion. It is an American seedling.

Robert Powell, terra-cotta-bronze, lined and flushed with purple, is one of the best Japanese varieties with incurving florets.

M. Bruant is bluish-white, suffused purple, with irregularly incurved florets.

Lady Hanham, a golden rosy-cerise sport from the popular *Vivian Morel*, will find many admirers when more widely known.

Julia Scaramanga in style is much like the preceding sport. Colour rich bronze terra-cotta, with a light golden reverse.

Royal Standard, a crimson flower, is the brightest in colour of any variety introduced this season. The florets are broad and flat.

Master H. Tucker is darker in tint of its crimson the slightly incurving florets show both colours readily.

Werther, reddish-purple, is showy, but not large.

Mrs. F. A. Bevan is a flesh-pink coloured variety with drooping florets.

Mlle. Laurence Zede is rosy lilac in colour, with narrow-pointed petals which incurve closely, making a full solid flower.

Incurved novelties are not numerous, it being less easy to obtain from seed varieties of this section equal to the best of those already in cultivation. If we can count annually upon half-a-dozen distinct varieties that show an improvement on some existing kinds, *Chrysanthemum* cultivators must be satisfied.

Mlle. Lucie Faure was sent out in the spring of the present year by Calvat as a Japanese incurved. It is now recognised by the Floral Committee of the National Chrysanthemum Society as belonging to the Chinese, or properly incurved section. Well grown blooms are certainly magnificent, measuring fully 5 inches wide, and as many deep. The florets are pointed, incurve regularly, and are of the purest white.

Mrs. N. Molyneux is an English-raised seedling from two well-known varieties, *James Agate* and *C. B. Whitnall*. Full-sized blooms are 6 inches wide and 5 inches deep, of globular form, and ivory-white in colour. The habit of growth is desirable, being in few cases higher than 4 feet to 5 feet.

Madame Ferlat is another of Calvat's 1897 introductions, and promises to be fully up to expectation.

The petals are narrow, the ground-colour white, with a faint pink flush. A full and promising variety.

Austin Canwell reminds one of Lord Derby in colour, except that the new variety has silver lines running through the reverse of the petals; a full and desirable variety.

Ernest Canwell is another type, and equally deserving of attention. In colour it is blush-pink at the base, with a yellow suffusion.

Mrs. W. C. Egan is best described as a pale-coloured P. Petfield, and as this is a favourite, the new variety is worthy of a trial.

Miss Dorothy and *Miss Violet Foster* were both distributed last spring from the same source. Both are likely to take a prominent position, as they possess all the characteristics needful to make sterling exhibition varieties. The former is silvery-mauve in colour, the latter silver-rose. *E. Molyneux*.

MAXILLARIA ELEGANTULA,

Rolfe, n. sp.

Our illustration (fig. 125) represents the pretty *Maxillaria elegantula*, shown by Messrs. F. Sander & Co., St. Albans, at the Royal Horticultural Society, November 23, 1897, when the Orchid Committee awarded it a Botanical Certificate. The bases of the segments are white, the outer halves pale yellow, marked with chocolate colour. Its nearest ally seems to be *M. fucata*, illustrated in the *Gardeners' Chronicle*, November 17, 1888, p. 577.

THE ROSARY.

ROSE: CLOTH OF GOLD.

THIS beautiful Rose, which was raised just fifty years ago by Quereau, and brought out under the French name of *Chromatella*, has, I think, been rather unfairly treated, and I am glad, therefore, that attention has been drawn to it. What I mean by being unfairly treated is this, it has been considered so difficult to flower, or, indeed, to keep alive, that people have not attempted its culture, and yet I look upon it as one of the most beautiful of our yellow Roses. Your correspondent has mentioned some examples of it to show that under certain circumstances it is very vigorous and long lived; though I think it must be a mistake to say its stem is 15 inches in diameter. I think that in many places in our southern counties, in suitable positions, it would thrive well; one such instance I well recollect. When I came to this parish thirty years ago there was a magnificent plant of it, which nearly covered the front of a house which was then inhabited by two ladies, one of whom was a great friend of the late Rev. Joshua Dix; she was very fond of her garden, in which she had collected many good things, but I think the especial ornament was this fine tree—when I first saw it, it was a sight not to be forgotten. The house faced about S.W., and the soil of the garden was light and sandy; it was well sheltered from N. and N.E. winds, and, of course, had, from its position, a good amount of sunlight. I counted, as well as I could, the number of blooms and buds on it on the day of my visit, and there were about 250, borne in true Noisette fashion, in clusters of three or four. And what blooms they were! firm of texture, and deep of build, with footstalks so strong that every flower was held erect. "But what about the colour?" some may say. Well, it has not the rich golden-yellow of *Maréchal Niel*, but neither has it the defect of that beautiful Rose, of hanging down its head. The colour is a soft sulphur-yellow, described by some of the French raisers as *jaune foncé*, and as long as it flourished it was always a treat to see it in flower.

Oh, then," you may say, "it did not live!" No; simply because it was killed. The two ladies died, and the landlord took possession of the place and altered it; he sent his head gardener to alter and improve the garden! no suburban gardener could have had a more vandalic idea of improvement than this good man. Many a choice shrub was sacrificed, but the

worse fate of all befell the Cloth of Gold; it was ruthlessly cut away, and like all Noisettes, it resented the insult, and although the stem was as thick as my arm, it never did anything afterwards, and it no longer exists. But I see no reason why, if it had been properly treated, it should not have lived on to the present time; and surely there are many situations in our southern counties where an equally good position might be found for it—and yet such is the general disfavour with which it is regarded, that it does not appear in the catalogue of the National Rose Society, either among exhibition or garden Roses.

My object in writing this is to try and induce growers who are favourably situated to make a trial of it. I once had an adventure with this Rose: it was in my very early days of Rose-love; and this flower has been one of the last to which I have paid my addresses. The Auricula, Carnation, Picotee, and Ranunculus, engaged my earlier affections, and so it came to pass in the days of my ignorance I saw some plants of it in pots at a nurseryman's in Lincoln. I was coming home, and actually burdened myself with carrying a plant of it. It had a promising bud, which flowered when I got it

FIG. 125.—MAXILLARIA ELEGANTULA.

home; but, alas! it did no more. Probably had it been twenty years later, I should have succeeded with it. Will not, therefore, some of our amateurs in the South of England give this fair Rose a trial?

As I am writing about Roses, and amateurs are busy planting, it may not be out of place to call their attention to the new form of Acme label, manufactured by Mr. John Pinches, Oxenden Street, Haymarket. It is the very perfection of a Rose-label: the name faces you, and there is no need of wetting the label to see what it is. It is really imperishable; and as I have had it now for two seasons in use in my garden, I can testify to its great comfort and neatness. Moreover, it is not dear, and amateurs who wish their Roses neatly and permanently labelled, will, I think, give me their thanks for drawing attention to it. *Wild Rose*.

AMERICAN NOTES.

PROTECTING PEACH-TREES IN WINTER.

PEACHES are very largely grown over wide areas in the States and in the province of Ontario, and there is a constant effort among amateurs to push their culture as far north as possible. The chief problem in this case is the protection of the tender

wood against freezing; but all over the States, south as well as north, a principal concern is to protect the swelling fruit-buds from late spring frosts. These questions have recently received an illuminating review, and a useful original experimental study by Professor Whitten of Missouri. Some of his conclusions are as follows:—"The early swelling and growth of the buds is due to the warmth they receive, is practically independent of root-action, and may take place on warm sunny days in winter, while the roots are frozen and dormant. Shading or whitening Peach-trees to prevent their absorption of heat on sunny days opposes growth of the buds, and is, consequently, a protective measure. Shading the trees with board sheds enabled Peach-buds to survive the winter uninjured when 80 per cent. of unprotected buds were killed. Whitening the twigs and buds by spraying them with whitewash is, on account of its cheapness and beneficial effects, the most promising method of winter protection tried. Whitened buds remained practically dormant until April, when unprotected buds swelled perceptibly during warm days late in February and early in March. Whitened buds blossomed three to six days later than unprotected buds, and 80 per cent. passed the winter safely when only 20 per cent. of unwhitened buds escaped."

In this same connection, the investigations of Mr. John Craig, horticulturist at Ottawa, are of interest. According to his observations, tender fruit-buds are not always correlated with tender leaf-buds. There is a striking difference among varieties of Peaches and Plums in the ability of their fruit-buds to withstand severe winter weather. The varieties of Peaches which Mr. Craig finds hardest in this respect are Hill's Chili, Loughurst, Barnard, and Early River. The hardest varieties of Plums (of the Domestic class) are, as regards the fruit-buds, the English Damson, Shropshire Damson, Blue Damson, and Canada Orleans. Other experiments by Mr. Craig also emphasise once more the inutility of mulching to retard blossoming in spring.

THE RÔLE OF THE SOLUBLE FERMENTS IN GERMINATION.

During the past year we have been making some very interesting experiments at the Vermont Experiment Station in the artificial use of enzymes, or soluble ferments, in the germination of seeds. Diastase is the reagent with which we have worked most, and with which we have had greatest success. It is well known that old seeds lose, in greater or less degree, their capability of germination. This, we assumed might be due to the weakening of the enzymic ferments known to be present in fresh mature seeds, and generally understood among physiological botanists to play an important part in the digestion of reserve materials in the seeds for the use of the unfolding plantlets. Our method of procedure is to make a 5 per cent. or 10 per cent. solution of fresh malt. The seeds are then soaked for twenty-four to forty-eight hours in the strained solution, the solution drained off, and the seeds planted. As a check in these experiments, an equal number of the same seeds are always soaked in water and planted beside the treated seeds. Although we have had many negative results, some of the positive testimony is really surprising. Tomato seeds twelve years old showed the following percentages of germination:—

Soaked in water	...	12 per cent.
Treated with pepsin, 5 per cent.	...	70 "
" " " 10 per cent.	...	80 "
" " Diastase (malt) 5 per cent.	...	84 "
" " " 10 per cent.	...	85 "

Thus the treatment with the stronger diastase solution gave an increased germination over the sample soaked in water of 608 per cent. Another sample of Tomato seeds, five years old, gave the following results:—

In water	...	76 per cent.
In Extractum Pancreatis	...	80 "
In Trypsin	...	86 "
In Enzymol	...	90 "
In Diastase Essence of Pancreas	64	"

Our experiments are only preliminary thus far, but they offer intensely interesting suggestions. Of

course, the most obvious practical application would seem to be the use of malt solutions in germinating old and weak seeds. The treatment is attended with scarcely any expense of time, trouble, or money, and, if it prove useful in practical work, can be undertaken by anybody. *F. A. Waugh.*

NEW WEST AMERICAN LILIES.

In *Erythraea* for October, 1897, Mr. Carl Purdy, the well-known bulb-collector of Ukiah, California, describes three new Lilies from the north-west:—

Lilium occidentale, the Eureka Lily, occurs in boggy places in barrens and woods about Humboldt Bay, occupying the place which *L. maritimum* takes further south; its nearest relative is *L. maritimum*, but it has larger flowers, with long revolute lobes.

Lilium Bakeri comes near to *L. columbianum*; its colour is a little more orange than the latter, "the lower portion dotted thickly with small maroon spots;" the segments of the perianth are closely reflexed from the middle. It is described as being "very fragrant, perfuming the air for rods around." Habitat: "Sandy woods along Puget Sound, in northern Washington and southern British Columbia."

Lilium parvum var. *luteum* differs from the type in the clear brilliant reddish-orange-coloured petals, not tipped with red, spotted with small spots of bright red. It is a native of Plumas Co., California. Mr. Purdy adds, "I do not agree with those authors who would limit *L. parvum* to the funnel-formed type, and throw any or all of those forms with reflexed petals into *L. pardalinum*. I consider the peculiar three-jointed scale, the pale foliage, and the shorter, rounder capsule more specific characters than the form of the flower, and would throw all of these alpine Lilies into *L. parvum*. *L. pardalinum* var. *minor* is, in my opinion, a form of *L. parvum*." *J. Burt Davy, University of California, Berkeley, California.*

HOME CORRESPONDENCE.

ROYAL HORTICULTURAL SOCIETY'S MEDALS AND AWARDS.—While there is both wisdom and truth in the observations by "Authority" at p. 402 on the above, and with which many will most cordially agree, it is difficult to discern the motive "K." had in view when penning the latter portion of a self-contradictory note. For on the very face of it with these medals of "lesser value," and so long as they are so relatively valueless, one cannot see the reason for the "avariciousness" that your correspondent assumes to exist in the desire to obtain them. Had these been money prizes I could have seen some ground for the remark; but so long as these Medals retain the merely nominal value they represent, the observation appears quite uncalled for. Surely "K." is not so woefully ignorant of the facts as to know that many of these Medals are given as some acknowledgment of successful culture of the plants, fruits, or flowers shown; for it is utterly impossible, even did the winner feel inclined, to turn them into cash, that they would repay even the time and travelling-expenses of the assistant private gardeners who are a necessity where large groups or collections are staged. That there are gardeners who only exhibit when a substantial money-prize is awarded is well known, and it is equally well known that in some of the most frequent exhibitors the Royal Horticultural Society finds its most staunch supporters—men worthy of the calling they are following, who regard it a part of their duty as head gardener to carry on a certain amount of exhibiting in the interests of the young gardeners, who now work with them, and who will remember with gratefulness the opportunities thus afforded them. Of this latter class there are happily gardeners who from personal experience must be each year pounds out of pocket by such exhibiting, while the only recompense is the Silver Medal, or what not, of the Society in question. And because a good gardener may, if he so choose, be a frequent exhibitor, and thereby secure a few of these medals, of no real worth, a correspondent like "K." assumes such action to be "pitiful," and as "degrading horticulture." The same correspondent would doubtless tell us that the finest soldiers of to-day are degrading the Army because these very men not only win and receive medals; for they proudly decorate their well expanded breasts with these reminders of the past. The gar-

dener does not go quite this far, and still clamour around for one more space to be occupied, but he quietly treasures such things in his private abode, and will doubtless reverse them in the years to come. The last suggestion of "K." is an impossible one, just at the moment when the Council of the Royal Horticultural Society have so signally announced themselves in favour of giving medals by their last creation in this direction. The gardeners who secured one of these latter will now be able to have a central figure in the decoration of their rooms by these well-won tokens. *Rez.*

THE LATE HORACE BILLINGTON.—The writer of the obituary notice of the late Horace Billington, Curator of the Botanic Garden at Old Calabar, is in error in stating that "it is also very unfortunate that a good man was not put with him to assist. . . . Such a man would have learnt very much from Mr. Billington's experience, and the Government would have had someone now to rely upon to continue the valuable work started by Mr. Billington" (p. 406). A competent gardener was sent out from Kew to Old Calabar to assist Mr. Billington a year and a half ago, as will be seen from the following extract from the *Kew Bulletin*, 1896, p. 147:—"Mr. John Henry Holland, a member of the gardening staff of the [Royal] Gardens, has been appointed, on the recommendation of Kew, by the Secretary of State for Foreign Affairs, Assistant Curator of the Botanic Station at Duke Town, in the Niger Coast Protectorate. He left Liverpool for Old Calabar in the middle of June." That Mr. Holland has given satisfaction is shown by the following official statement by Mr. Billington himself, and also by one from H.B.M. Commissioner in the Niger Coast Protectorate:—"Old Calabar, Aug. 12, 1897. During the time Mr. J. H. Holland has been in the service of the Botanical Department, extending over a period of thirteen months, both as Assistant Curator and as Acting Curator, he has performed his duties in a satisfactory manner, and worked hard. Mr. Holland is well-informed on the cultivation of economic plants, as well as in other branches of horticulture (Signed) Horace W. L. Billington." "I have found Mr. Holland a reliable and hard-working official (Signed) R. Moor, H.B.M. Commissioner and Consul-General." In justice to Mr. Holland and to Kew, I shall be much obliged if you will publish this statement. *W. Watson.*

YELLOW BANKSIAN ROSE.—I am sending you two sprays of the yellow Banksian Rose, picked from a plant growing on the front of Mr. J. C. Walkey's house at Ide, near Exeter, and wholly unprotected. Quite recently I saw a farm-house, near Dawlish, with *Solanum jasminoides* covering half of the front, and blooming profusely. Cowslips, Polyantheses, Primroses, Pansies, and the like have been very plentiful up to the beginning of this month in gardens near Exeter. *A. H.*

TESTACELLA HALIOTIDEA.—So far as my experience goes, these worm-eating slugs, which have been so freely commented upon of late in your columns, are much more widely distributed than people imagine. I find them here in quantities, but most abundantly in spring; the larger ones often in the act of devouring a worm apparently twice its own size. At this season of the year, scarcely a day passes but I see one or more on the land, from quite small ones not larger than a straw, to the full grown, as large in circumference as the small finger. Where a box has been left on the damp earth a day or two, there one may almost be certain of finding the above species. *E. Jenkins, Hampton Hill, Middlesex.*

STANDARD ROSES.—It is narrated of Mr. Woods, who came from Paris to Maresfield in 1824, that he sent some standard Roses from Paris to a builder at Brighton, desiring him to have them planted in a garden attached to a house then in course of construction. The recipient of the Roses acknowledged the receipt of a "bundle of sticks," from which some thief had stolen the Roses. Directions were, however, given that the sticks should be planted root downwards, and next year many of the Brightonians were delighted with their first sight of a standard Rose. *C. W.*

POTATO-SPIRIT.—It would be interesting to know what proportion of the Potato crop of Europe is devoted to the production of spirit. We know in a general sort of way that it is a large one in Germany, Poland, and Austria, and enormous quantities of the tubers find their way to the distillery and the starch manufactory; but what this propor-

tion bears to the whole, is not generally known in this country. The spirit obtained from the Potato is commonly consumed by the peasantry in those countries, it being very cheap and not very potent, and takes the place of beer and wine with the poorer classes. The poisonous principle of the Potato, solanin, cannot be any means known at present be entirely separated from the distilled product, and it acts very injuriously on those who indulge largely in Potato-spirit drinking, otherwise no perceptible ill effects follow moderate use. Much harm is undoubtedly caused to the natives of Africa and Polynesia, who, unacquainted with evil effects of the crude spirit sold to them by the trader, indulge in immoderate consumption with lamentable effects. *Traveller.*

AUTUMN v. SPRING DIGGING.—Mr. Easter, who writes so well on this subject, I notice, assumes that autumn-digging of stiff or clay soils is almost a necessity. Having had to work for twenty years several acres of as tenacious a description of soil as Middlesex can show, I may tell Mr. Easter with some knowledge, that early winter-digging of such soil was either a success or a lamentable failure, just as the winter was dry or wet. Given a wet winter, then the after-condition of the dug soil was greatly worse than that of the undug; indeed, taking the average of seasons, I found it was far safer and wiser to leave digging to the spring, as the ground then would work fairly well; whereas if early dug, a wet winter, or even a few heavy downfalls of rain, would leave the soil saturated, pasty, clinging, and absolutely unworkable. Naturally, one wishes to get ground dug during the winter, to at once facilitate spring-work, and to furnish labour in the winter, but the results were always distressing if the season was at all wet. Even if thrown up over so rough, and frost came, and broke up and pulverised it, yet so soon as rain came, the fine broken surface became literally mortar, and, choking up the soil-pores and worm-holes, then dried, left the ground hard and impervious. Generally, for clay soils, it is far better to allow them to remain all the winter untouched, but, if possible, carrying a green crop of some sort, even if but weeds, because such vegetation does gather and convey into the soil fertile elements, whilst barren or fallow soils simply allows them to waste. Still, this is old teaching, literally as old as the hills; but sound as it is, it is too little put into practice. Why is there such a dead set raised against earth-worms that readers want to increase the carnivorous Testacella? Do not the earth-worms play a most valuable part in the economy of soil creation and cultivation? work that seems to be too little recognised. *A. D.*

NEW VIOLETS.—At the recent Chrysanthemum show in Brighton some of the finest Violets I have ever seen were shown by Messrs. J. House & Son, of the Coombe Nurseries, Westbury-on-Trym, near Bristol. These were large, of nice colour, and very fragrant. One of the best was California, a strong grower, double the size of our well-known Improved Czar, and of an intensely deep violet-purple. The stout stems were from 10 to 14 inches long. Princess of Wales, a large dark-tinted variety, was said by Mr. House to be the largest in cultivation; the stalks were not quite so long as in California, nor was the fragrance as pronounced, but the flowers were carried boldly upright. Italia and Primavera were also exceptionally good. A variety called St. Helena was of a clear lavender colour, rather brighter than that found in the Neapolitan. All of these single-flowered Violets are of recent introduction. They are exceptionally strong growers, flowering very freely, as shown by the plants in pots staged at the same time, and of much use for autumn and spring flowering. *A. P.*

AN ELEVATED ORCHARD IN THE WEST.—"Pomona" (in issue *Gardeners' Chronicle* for November 13, under heading of "Enquiry"), will probably run the risk of only nominal drawbacks if planting as described at 600 ft. elevation in Gloucestershire, by making the choice of varieties as if there were no question of elevation at all to impose restrictions. I named in last week's issue, under "Yorkshire Apples" a selection of varieties for the neighbourhood of Hull, all of which would be desirable for Gloucestershire, and certainly Cox's Orange Pippin should not be excluded, nor Ribston neither, the Apples referred to being all dessert varieties. Amongst culinary Apples, all the large tried varieties, such as Early Rivers, Stirling Castle, Lord Suffield, Grenadier, Lord Grosvenor, The Queen, Bismarck,

MISCELLANEOUS PLANTS, &c.

The best collection of *Cyclamens* in pots was from Mr. W. Oarwood, Andover Nursery, Uxbridge; and the best group of twelve *Cyclamens* in pots (nurserymen excluded), was from Mr. W. Frost, gr. to S. ASHLEY DODD, Esq., Ashford, Kent; who was followed by Mr. W. Rapley, gr. to H. GAINING, Esq., Harrow Weald House, Stenmore. This latter exhibit was short of colour, otherwise it was little inferior in quality to the 1st prize exhibit.

Mr. J. Gibson, gr. to E. H. WATTS, Esq., Devonhurst, Chislewick, was 1st in the class for a collection of plants of *Primula sinensis* (open) with a very creditable exhibit. They were interspersed tastefully with pretty *Crotons* and graceful *Palms*.

The class for twelve *Primula sinensis* (nurserymen excluded) fell to Mr. W. Mease, gr. to H. TATE, Esq., Downside, Leatherhead, who was followed by Mr. Gisson.

A collection of flowering, berried, and foliage plants, arranged for effect upon a table, and shown by Mr. Gisson, deserved praise as being composed of pretty, well-grown specimens of the different species. Its only fault was due to an effort to include a greater number of plants in the space than there was need for.

For the best basket arranged with autumn berries and foliage there were as many as ten competitors, and the 1st prize was won by Mr. Newell, gr. to Sir E. SAUNDERS, Fairlawn, Wimbledon.

NON-COMPETITIVE.

There were many exhibits staged other than those for competition, and one of the most remarkable of these was a group of plants and cut blooms from Mr. W. WELLS, Earlswood Nurseries, Redhill. The group consisted of two elbows with a division in the middle, where a miniature lake, containing fish, was formed on the floor. Around this was a setting of moss with a few Ferns, and a bordering of cork. There were cork arches too, and some of the stands for the blooms were relieved with the same material. This style is hardly appropriate in the grouping of such plants as the *Chrysanthemum*, and, when adopted, it is necessary to secure excellent finish.

Mr. H. J. JONES, Ryecliff Nursery, Lewisham, filled a large table with blooms of many varieties of *Chrysanthemums*, inclusive of a number of novelties. They were well relieved by pretty foliage plants.

Messrs. H. CANNELL & SONS, Swanley, Kent, showed *Chrysanthemum* blooms, and something very much brighter, in their stand of sprays of *Pelargonium* flowers, which were very attractive. This firm also contributed some excellent vegetables.

Mr. W. J. GODFREY, Exmouth Nurseries, Devon, and Mr. R. OWEN, Maidenhead, contributed blooms of numerous varieties of *Chrysanthemums*.

Mr. J. R. CHARD, florist, Stoke Newington, had some pleasing floral arrangements; and a similar exhibit was staged by Mr. W. GREEN, Jr., Harold Wood, Essex, who showed excellent taste in the several designs.

A splendid exhibit of eighteen bunches of Grapes was made by Mr. W. Taylor, gr. to C. BAYE, Esq., Tewkesbury Lodge, Forest Hill, S.E. Mr. T. ROBINSON and Mr. W. NEVILLE contributed *Chrysanthemum* blooms; and Mr. BASIL, gr. to D. H. EVANS, Esq., Shooter's Hill, Pangbourne, a collection of vegetables.

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.

DECEMBER 4.—This Association held its monthly meeting at Newport, on the above date. Mr. J. GROVES presided over a large attendance of members; and Mr. C. MARTIN, Clarence House Gardens, East Cowes, read an excellent paper on "Codium, Caladiums, and Dracenas," which evoked an interesting discussion.

Mr. W. W. SHREATH, Macrocarpa, Ventnor, staged leaves of *Crotons* and *Dracenas* to illustrate the subject, and made a few remarks on the various methods of propagation and general cultural requirements.

Mr. J. H. SILSBURY staged a fine bloom of the *Chrysanthemum Julia Scaramanga*.

A PLEASURABLE INCIDENT.—On Thursday, December 2, Mr. F. Elliot, gardener to Mrs. W. L. Barclay, The Briars, Reigate, was, on the occasion of his marriage with Annie, daughter of Mr. T. Wortley, Beltham, Grantham, the recipient of a handsome marble clock, subscribed for by the workmen in the gardens of Lord Brownlow at Belton, where Mr. Elliot was foreman in the kitchen garden and forcing department for a period of five years.

MARRIAGE OF MR. ARCHIBALD FORBES, SON OF MR. JOHN FORBES.—At Marlfield, Hawick, on the 3rd inst., by the Rev. Charles Allan, M.A., assisted by the Rev. Duncan Stewart, M.A., Archibald Forbes, Buccleuch Nurseries, Hawick, to Eleanor Snowden, eldest daughter of Mark Currie, Esq. Mr. Forbes was, on the occasion of his marriage presented with a handsome barometer

from the nursery employes, Mr. W. Oliver, on behalf of the men, making the presentation. The office-bearers of Freemasons' Lodge, St. John, No. 111, met in the Crown Hotel, and presented the happy man with a beautiful silver salver, which was suitably inscribed. R. W. M., Brother James Barrie, in a feeling speech, made the presentation.

The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending December 4, is furnished from the Meteorological Office:—

"The weather was very unsettled and squally during the earlier half of the period, with considerable falls of cold rain or sleet in all the northern parts of the kingdom, and of rain or hail, and occasional sleet elsewhere. The rainfall was especially heavy in the north-west of England, and North Wales. Towards the end of the week the conditions became finer and drier over the more southern districts, but continued changeable, with frequent rain elsewhere.

"The temperature was below the mean, the deficit ranging from 1° in 'Ireland,' the 'Channel Islands,' and 'England, N.E.,' to 3° in 'Scotland, E.,' and the 'Midland Counties.' The highest of the maxima were recorded during the earlier part of the week, and ranged from 55° in the 'Channel Islands,' and 64° in 'England, S.W.,' to 47° in 'Scotland, N.,' and 'E.' The lowest of the minima were registered either on December 3 or 4, and ranged from 19° in 'Scotland, E.' (at Braemar), and 20° in 'England, E.' (at Rothamsted), to 27° in 'Ireland, S.,' and to 37° in the 'Channel Islands.'

"The rainfall was rather less than the mean in 'Scotland, N. and W.,' as well as in 'England, S. and S.W.,' but more in all other districts. In 'England, N.W.,' the fall was nearly four times as much as the mean. The greatest aggregate falls for the week at any individual stations were 3.21 inches, at Llandudno, and 3.12 inches at Manchester.

"The bright sunshine exceeded the mean in all districts except the 'Channel Islands.' The percentage of the possible duration ranged from 36 in 'England, S.,' and 34 in 'Ireland, S.,' to 20 in 'Scotland, E.,' and to 17 in 'Scotland, N.,"

MARKETS.

COVENT GARDEN, DECEMBER 9.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. No.]

POTATOES.

Trade slow, arrivals somewhat lighter. No advance in prices. Up-to-dates, 85s. to 115s.; Maincrop, 80s. to 100s.; Saxons and Bruce, 80s. to 95s.; Blacklands, 70s. to 80s. per ton; Belgian and Dutch Ware, 3s. to 8s. 6d.; German Ware, 3s. 3d. to 5s. per bag. John Bath, 32 and 34, Wellington Street, Covent Garden, W.C.

SEEDS.

LONDON: December 8.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that although to-day's seed market was well attended, the business passing was confined to very narrow limits. Indeed, just now no disposition whatever is shown to purchase either Clover or Grass seeds. There is no change in either Tares or Rye. Full prices are asked for Mustard and Rape seed. Blue Peas and Haricot Beans show no alteration. As regards Hemp, Canary, and Millet seeds, the transactions passing are on a meagre scale. Fine new Scarlet and White Runner Beans offer on tempting terms. The new Spanish Lentils come cheap and good. Linseed is steady.

THE

Gardeners' Chronicle.

SATURDAY, DECEMBER 18, 1897.

A FRENCH GARDEN IN 1545.

I HAVE just met with a little book of 140 pages, entitled, *De Re Hortensi Libellus*. It is written, and dedicated to his "little grandson" (Nepotulus Henriculus), by Carolus Stephanus, because his "little Henry," when quite young (*tenellus*), had been devoted to flowers. He sends his *Hortulus* to him to refresh his mind and eyes when wearied with his daily studies.

He commences by giving a supposed origin of the word *hortus*, and some account of the gardens of the ancients, mainly taken from Pliny, in which were principally Cabbages and root-plants, such as Carrots, &c., as well as pot-herbs and kitchen-herbs; or else the gardens were planted with trees overhanging shady walks. He also alludes to the "hanging gardens" of the ancients, which were made on the tops of arches. He then proceeds to give descriptions of all the plants to be grown, first mentioning the wild plants which come up spontaneously in a garden, such as Ivy, pellitory of the wall, the "yellow Violet" or Wallflower, Celandine with its yellow juice, Houseleek, Polypody, Adiantum and Asplenium, &c. Then follows a description of hedge-plants, in which *Oxyacanthos* still stands for Barberry, as in the fourteenth century; the Privet, Dog-rose, three kinds of *Rubus*, *Rhamnus*, i.e., Gooseberry, &c.

Walks, open and protected, are next treated of; and the author alludes to the roofing with the "specular" stone of the ancients, in other words to mica, which Pliny says rarely exceeded a few feet in length. Of plants used for trellises, and to arch over the pathways, he speaks of the Vine, Rose, Briony, white and black (*Tamus communis*).

Next comes the proposed arrangement of the flower-beds or *Areae*, each being devoted to some special kind of plant. The first is *Area coronalis*, i.e., for such plants of which the flowers were used for garlands and bouquets; 2nd, *Area odorata*, containing plants with scented flowers, leaves, or roots; 3rd, *Area olitoria*, including one bed for salad-plants, another for condiments; 4th, *Area escaria*, for vegetables; 5th, an *Area* for vegetable-fruits; and 6th, for root-crops.

Each of these *Areae* is treated in full, and all the plants usually cultivated are described in detail, as follows:—

Area coronalis.—Of scented flowers used for wreaths, the author describes the White Stock, Wallflower, Violet, Dame's Violet, Betony, *Narcissus biflorus* and *N. poeticus*, Marigold, *Baccharis*, a Boraginaceous plant, apparently *Anchusa*; Lilies, white and red, probably *L. Chalcedonicum*, the Lily of the Valley, Iris

Pseudacorus, and *I. Florentina* "with a more highly-scented root and white flowers."

Of plants without scent are Columbine, *Amaranthus*—the Coxcomb was apparently unknown in the sixteenth century, though Gerarde's figure looks like a commencement of fasciation—*Flos Jovis*, which the author translates by "*Des coquelourdes*," i.e., Pasque flowers, *Anemone Pulsatilla*; but others take it to be a *Lychnis*; *Petilius*, a flower unknown to him, commonly called "Belueder" by the Italians, and in France "*Oeillets d'Inde*." It is named from *Petilius*, a town of Lucania, an autumnal flower "with a striated calycul, resembling a Rose." The plant grows to a great height, and dies yearly. This reads like a Holyhook. *Flammea*, or lesser Pansy; *Consolida minor* or "*Marguerites*," i.e., the cultivated form of the Daisy.

Area odorata.—This should contain *Artemisia abrotanum* or Southernwood, *A. absinthium*, *A. ponticum*, &c.; *Galeopsis*, which appears to be *Leonurus Cardiacus* or Motherwort; *Amaracum*, *Maiorata* or *Sampsychus*—these three names referring to one plant. *Matthiolus* in his commentary on *Dioscorides* (ed. 1560), figures *Marjoram*; *Galen*, our author adds, regarded it as *Parthenium* or *Matricaria*, and he gives the French name "*Espargoutte*" or Feverfew. The author, however, alludes to the difficulty of unravelling the various names of the ancients. *Calamintha*, commonly called *herbe-au-chat*; i.e., Catmint, *Nepeta Cataria*; another kind being *Nepeta*, but he admits the confusion; for this last is the Catmint. Three kinds of *Marjoram*: viz., *Heracleoticus*, *Onitis*, and the wild *Marjoram*; *Matthiolus* figures all three kinds; *Mentha*, or different kinds of Mint; *Costus hortensis*, "*du Coq*," our *Costmarie*, *Pyrethrum tanacetum*, from south Europe. *Hyssopus*, *Nardus celtica* or Lavender; *Ozimum* or basilicon, Balm; *Ocymastrum*, the *Acinos* of *Dioscorides*, wild balm, *Salvia*, Sage, *Satureia* or *Thymbra*, Savory; *Rue*, Tansy, *Chamomile*, *Thyme* and *Epithymum*, i.e., *Cuscuta* or Dodder parasitic upon it. *Prasium*, two kinds, viz., *Horehound* and *Ballota nigra*; *Stachys*, called Mountain Sage; *Melissophyllum*, probably *Melittis Melissophyllum*, *Bastard-Balm*; *Orminum*, in Fr. "*Toute-bonne*," our *Clary*, *Salvia*; *Verbenaca* and *Anethum*, Dill. *George Henslow*.

(To be continued.)

NEW OR NOTEWORTHY PLANTS.

MARATTIA BURKEI, *Hort. Veitch* (fig. 129, p. 435).

THIS Fern was exhibited lately at the Drill Hall, at one of the fortnightly meetings of the Royal Horticultural Society, and received a Certificate. It was collected by the late Daniel Burke (after whom it is named), whilst travelling for Messrs. Veitch. The native country is not known with certainty, but as he spent some time in Columbia, and its affinity with *M. alata*, Smith, is very close, it is most likely that it inhabits that part of the world. At present it is only in an undeveloped state, so that its botanical position is uncertain. The following provisional description was made from a living specimen:—

Stock stout, prickly, green, above a foot long, without any scales. Frond square, tripinnate, above a foot long and broad, bright green and glabrous on both surfaces. Pinnae in four opposite pairs without one at the end of the main rachis, oblong, the lowest pair smaller than the others. Pinnules crowded, lanceolate, ten- to twelve-jugate. Tertiary segments oblong, sessile, obtuse, the longest 1½ inch long, deeply regularly crenate, unequal at the base. Veins distinct, simply erecto-patent, running from the midrib of the segments to the end of the lobes. Sori not yet developed. *J. G. Baker*.

ORCHID NOTES AND GLEANINGS.

COMPARETTIA MACROPLECTRON.

PLANTS of this pretty species are now flowering, in pans containing ten or more plants, in the warm Orchid-house in the Botanic Garden, Edinburgh. The pendulous, many-flowered racemes have rose-coloured sepals and petals, are much speckled with red, and the flowers are the largest of any of the genus. Although the spur appears outwardly single, it really consists of three, the two from the labellum being inside the larger one from the united lateral sepal. The leaves are about 5 inches long, and rusty-coloured on the under surface. The plant requires at this season scarcely any water, but a fairly liberal quantity is necessary when the plant is growing, as the scanty compost used must be well drained, and open. This species is a native of Columbia, and was introduced in 1878. *R. L. H.*

LÆLIA AUTUMNALIS DELICATA.

A fine inflorescence, bearing three flowers, of the large type of *Lælia autumnalis* known as *atrorubens*, but differing from it in having white flowers very slightly tinted with the most delicate flush of rose colour, is sent by Frau Ida Brandt, Brunnenhof, Riesbach, Zurich (gr., Mr. Schlecht). The disc of the lip bears the usual pair of raised lines, but of a very pale yellow tint, and the apex of the column is tinted with light rose. The greater part of the white or nearly white varieties in cultivation are of the old type of *L. autumnalis*, plentiful in gardens many years ago, and which made the *L. a. atrorubens* and its varieties on their arrival more welcome than many of the new species.

CALANTHES, &c., AT SHERFIELD MANOR, HANTS.

In the gardens at Sherfield Manor at present is a grand show of *Calanthes*; the three varieties are *C. Veitchi*, *C. vestita rubro-oculata*, and *C. v. lutea*, on which some hundreds of flower-spikes are in full beauty. In one of the houses the *Calanthes* are mixed in amongst a number of very fine plants of *Adiantum Farleyense*, with a pretty effect; and in another the white *Calanthes* are mixed with *Poinsettia pulcherrima*, offering a brilliant effect; and lastly, *Calanthes* were mixed with capital plants of *Codæums*, *Dr. cœnas*, and other stove plants, with much good taste. The *Calanthes* are potted in 4 and 5-inch pots, in a mixture of loam, peat, sand, and a small quantity of dried cow-dung. The spikes vary from 4 to 4½ ft. in length, and carry from thirty to forty blooms on a spike. One pseudo-bulb only is planted in a pot, and they have made some two or three pseudo-bulbs, and each has flowered. The blooms are so large and thickly placed that they almost overlap one another; and the stems being strong need no stakes for support. Mr. Wasley, the head gardener at Sherfield Manor, is a good cultivator of other choice plants, many of which may now be seen in fine groups of *Bouvardias*, *Cyclamens*, tree *Carnations*, zonal *Pelargoniums* in full bloom, *Primulas*, *Cinerarias*, and many others. Sherfield Manor is the residence of J. B. Taylor, Esq., and is at the present time undergoing considerable alterations in the mansion and grounds. *J. W. McHattie, Strathfieldsaye*.

TREES AND SHRUBS.

CUPRESSUS MACROCARPA LUTEA.

THIS is a new Conifer of recent introduction, which will, when known, scarcely fail to become one of the most useful variegated forms of the Cypress. Its style of growth and general contour are so striking that few people who have seen it fail to take a second glance, as its bright golden colour is more brilliant than that of *C. Lawsoniana lutea*, which has hitherto been one of the best; while, like the type, it possesses that delightful fragrance, which to most people is one of its characteristics. The typical species, *C. macrocarpa*, the *C. Lambertiana* of some botanists, is a native of South California, from whence it was introduced to this country in 1847.

Few large specimens are met with in this country, owing to the difficulty of transplanting, their coarse and wiry roots being a great drawback, consequently they have to remain where first planted. Some fine specimens can be seen in the neighbourhood of Woking, one especially over 20 feet high, in Brookwood Cemetery, being well furnished, and beautiful in appearance, while several smaller trees can be noticed in the same place. Now that a variegated form has been produced, it may cause both of these handsome trees to be more extensively planted than hitherto. *E. S., Woking.*

DIPANTHUS CERCIIDIFOLIA, Maximowicz.

It is over thirty years since Maximowicz described this shrub, but it has, so far as English gardens are concerned, been almost or quite unknown till within the last few years. At the beginning of 1893, seeds of it were received at Kew from Professor Sargent, of the Arnold Arboretum, Mass., which he had gathered during his then recent travels in Japan. These seeds were sown at the time they arrived, but remained dormant for over three years, a single seed germinating in May, 1896. This fact may be worth recording for the benefit of those who have obtained, or may obtain, seeds of this shrub from Japan, for judging by this autumn's experience, it appears likely to make a valuable addition to hardy shrubs. Professor Sargent says that in the autumnal colour of its leaves it was one of the most beautiful shrubs he saw in Japan, and it was this character which made the small plant at Kew so noticeable a few weeks ago. With the possible exception of *Rhus coccinoides*, it was the most striking in its autumnal colouring of any tree or shrub at Kew this year, the leaves assuming, before they fell, a rich claret colour. It is said to grow 8 feet to 10 feet high, and the leaves are 3 inches long, the same in width, and broadly ovate with a cordate base. The plant is aptly named, for the foliage greatly resembles that of the Chinese Red-bud (*Cercis chinensis*); it belongs, however, to the Witch-Hazels (*Hamamelis*), and judging by the figure in the *Forest Flora of Japan*, its flowers are very similar to those of that family. They appear in October, are dark purple, and are borne in pairs, back to back as it were, on slender stalks, the corolla consisting of five narrow, pointed, crooked petals. There ought to be no great difficulty in obtaining this shrub in quantity. Sargent says it is not rare in the valley of the Kiso-gawa, in Central Hondu, where it is sometimes seen covering hillsides with thickets a quarter of an acre in extent. Of its hardiness in this country little can be said at present. *W. J. B.*

Pinus flexilis.

In the *Gardeners' Chronicle* for September 18, 1875, there is a figure of the cones and leaves of this Pine, drawn by Mr. W. G. Smith from an imported specimen of Roessl's, together with a note on the species by Mr. A. Murray. But since that time little seems to have been heard or written about it. Even the *Report of the Conifer Conference* (1892) contains no reference to specimens growing in Britain, although Mr. Murray observed that it had been abundantly introduced to this country during Jeffrey's time as a collector and subsequently. There is a group of trees in the Pinetum at Kew (near the Ialeworth Ferry Gate), which shows the species to be by no means one of the least handsome of the Pines. The largest are about 25 feet high, and one is now bearing several cones. It is a tree of distinct appearance, having leaves about 3 inches long, produced in bundles of five, the younger ones appressed to the stem as in *P. Balfouriana*; in transverse section the leaf is triangular, and the two inner faces are striated with glaucous lines. The branches are long and slender, and their curving upwards, especially towards the ends, is one of the distinctive characters of the tree as represented at Kew. The cones are 3 to 4 inches long. According to Murray, who saw it wild on the Rocky Mountains and the Sierra Nevada, it varies greatly in stature and habit. High up the mountains, where it is exposed to the coldest blasts, "it is," he says, "reduced to a trailing shrub 1 or 2 feet high, wandering over the ground, and with its foliage so

densely packed that a man could almost walk over it." At lower altitudes, and under more clement conditions, it attains the size of the Scotch Pine in this country. The specimens at Kew are quite erect, clean-grown, and symmetrical. *W. J. B.*

ELÆAGNUS MACROPHYLLA.

In gardens where the soil is impregnated strongly with lime, and the satisfactory cultivation of Rhododendrons and other Ericaceous plants consequently difficult and expensive, the choice of hardy evergreens becomes greatly limited. As this shrub is comparatively little known—although in some respects the most striking of the evergreen *Elæagnus*—it may be worth while to draw attention to it here. I have only had experience with it in the London district, but here it is of undoubted hardiness, having stood outside at Kew without shelter or protection during the last ten years at least. It may at once be distinguished from the other hardy evergreen species by the shape and size of its leaves, which are larger than in any of the others; they are 3 to 4 inches long, broadly ovate-oblong, and on the upper side are of a dark and glossy green, whilst beneath they are of the peculiar metallic, silvery-grey colour common to many species of *Elæagnus*. It succeeds well in the extreme south-west of England, where large specimens are occasionally to be seen. It flowers there, apparently, more freely than it does near London, a large bush at Kew, 6 feet high, never having flowered as yet. In Messrs. Veitch's nursery at Coombe Wood, however, I saw it in bloom during November, both last year and this, but the plant is growing against a wall. The flowers are shaped like tiny Fuchsias, and are of the same colour as the under-surface of the leaves; their most charming character is the delicate Gardenia-like odour. It is a native of China and Japan. *W. J. B.*

APPLE DUMELLER'S SEEDLING.

WHEN recently looking through one of the gardening periodicals, published in the year 1850, I came across some particulars relative to the origin of this well-known Apple, which may have an interest for many readers of the *Gardeners' Chronicle*, as they amplify the details given in *Hogg's Fruit Manual*. It was raised by a Mr. Richard Dumeller, farmer, then residing at a farm-house known as Hop John's Hill, in the parish of Swepton, Leicestershire, about three miles south of Ashby-de-la-Zouch. Mr. Dumeller removed from this farm to one at Shuckstone; and, eventually, the farm passed into the hands of a Mr. Richard Spencer, and with it the original tree, which was in a flourishing condition fifty years ago. The writer of the article from which I am quoting, a Mr. Timothy Brown, says, "When a youth, I was sent by father to Hop John's Hill, to obtain grafts from Mr. Dumeller's tree, to work in my father's nursery. The tree had at that time a bole of about the thickness of a person's thigh, and showed slight symptoms of canker, to which it is liable when grown on a cold substratum." Mr. Dumeller appears to have taken pleasure in supplying grafts of his Apple, calling it his "Pippin," meaning in his mind that it was raised from a pip. It had the name Normanton Wonder attached to it in this way:—"Mr. Hesfield, a market gardener, residing at Normanton-on-Soar, was a native of Packington, and occasionally visited his friends at that place. Mr. Walker, a nurseryman, of Packington (which is within a mile of Hop John's Wood), worked the Apple largely, and sold it very freely. By him it was supplied to Mr. Hesfield, of Normanton, and the probability is that this handsome and useful variety soon became popular in certain markets, to which it was supplied from that locality, hence its new name.

In his *Fruit Manual*, Dr. Hogg tells us how it came southwards. "It was first introduced to the neighbourhood of London by Mr. Richard Williams, of the Turnham Green nurseries, who received it from Gopsall Hall, the seat of Earl Howe, who presented specimens of the fruit to the London Horticultural Society in 1820. It was with him that it received the name of Duke of Wellington, subse-

quently shortened to Wellington, and by which only it is now known in the London markets." It would therefore appear that the proper name of this valuable late variety is Dumeller's Seedling, though we have it on the authority of Dr. Hogg that the name is locally pronounced Dumelow. *R. Dean.*

TRADE NOVELTIES.

MESSRS. R. VEITCH & SON, Exeter, are sending out a new Melon, "Taunton Hero," which they claim to be the best white-fleshed Melon in cultivation. The shape is globular, lightly netted, and the colour golden-yellow. In heat it attains a weight of 5 to 6 lb., but in a hot-bed frame an average weight of 4 lb. is attained.

The same firm announce a new Cucumber, Veitch's Western Wonder, embodying, says the raiser, the colour of True-and-Tender, the quality of Lockie's Perfection, and the hardiness and fruitfulness of Telegraph.

Veitch's Earliest-of-All Cabbage is recommended for spring sowing, and received an Award of Merit at the Royal Horticultural Society.

ROIROIRE PÈRE ET FILS, LYON:—

Begonia semperflorens, Vernon.—Leaves with the golden-yellow foliage of Bijou, but each leaf is bordered with a dark red band.

Lobelia Rivoirei.—Flowers clear, rose-coloured. Perennial. It does best in the open ground. The seeds germinate with difficulty, and should not be covered with earth.

HERB & WULLE, NAPLES:—

Corydalis rotundifolia.—Flowers carmine.

Galanthus cilicicus.—A very early-flowering variety.

Iris persica Vogeliana.—Flowers silver-grey, with a large claret-coloured spot, but colour said to be variable.

Ornithogalum Hausknechti.—Spring-flowering. Flowers white.

Ornithogalum libanoticum.—Similar to the preceding, but earlier.

Tulipa pulchella.—A dwarf variety, with deep carmine colour.

J. C. SCHMIDT, ERF. ET:—

Earliest Iron-head Savoy.—"Large, tender, firm."

Erfurt Marrow.—Dwarf French Bean.

Miracle Pumpkin, "with stainless pits."—Fruits dark green, striped with yellow.

The Strawberry-Raspberry.

Sweet Pea Cupid.—Rose and white.

Campanula mirabilis.

Petunia Favourite.

Petunia Venus.

Begonia semperflorens, Zulu King, &c.

C. LORENZ, ERFURT:—

Cucumber Table Queen.

Frame Cucumber, Old Chancellor.

Heliandrus, Golden Bouquet.

Ageratum, Blue Perfection.

Gloxinia Galatea.

LÆLIO - CATTLEYA CLIVE (C. DOWIANA ♀, L. PUMILA (P. TANS) ♂).

THIS, one of the handsomest of the compact-growing hybrids, was raised by Norman C. Cookson, Esq., Oakwood, Wylam, Northumberland (gr. Mr. Wm. Murray), and first exhibited by him in 1893. At that time there was some confusion caused by the idea entertained by some that *Lælia Dayana*, now admitted to be a distinct species, was only a variety of *L. pumila*, and hence the interference that *L. C. Clive* could differ only in a slight degree from *L. C. × Ingrami* (*L. Dayana* ♀, *C. Dowiana* ♂). Time has, however, proved to the contrary, as was well demonstrated in the plant exhibited by the Right Hon. Joseph Chamberlain at the Royal Horticultural Society on November 23, 1897, which forms the subject of our illustration (fig. 126, p. 427). The sepals and petals are bright rose-coloured, the former rather the lighter. The lip rich maroon-purple, with golden-yellow base, bearing some fine reddish markings.

METHODS OF PROPAGATION.

(Continued from p. 390.)

BERBERIS FROM SEED. — Persistent shrubs are raised from seed as well as provided by the various methods I have indicated in papers, the seed, in some cases, needing no attention, in others calling for it. *Mahonia aquifolium* produces its purple Grape-like fruits in abundance, and blackbirds, thrushes, and other birds are partial to them. The seeds pass unaltered through the stomachs of these birds, and numerous young plants may generally be found growing in the open, the covert, bed, or border planted with any of shrub. This is also the case with another useful covert shrub, *Leycesteria formosa*, the fruit of which is eaten by the larger wild birds, as

timber tree in the south and west of Ireland. The fruit is edible, and much liked by thrushes and blackbirds, so that in hard winters few are left on a tree. It is prudent to gather the fruits when ripe and soft, rubbing them in sand, and sowing the seed forthwith in pans or boxes, which must be kept close in a cold pit, when it will germinate the following year. The seedlings, when they have acquired a few true leaves, should be pricked off into boxes or pots, about ten in a 48-sized pot, kept close, and shaded for a few days, and when established, plunged in the open in ashes or spent tan; but in the north and the midlands they will require protection by mats or straw coverings in the winter while young. A few should be potted singly in thumb-pots, as *Arbutus Unedo* forms the stock upon which the various hybrid forms as *Rollin-oni*, as

seedlings may be lined out in nursery-beds in the autumn. There is always a demand for this shrub in seaside towns, as coming from both the European and African shores of the Mediterranean, as well as from Corsica and other islands in the same sea, it loves the sea spray.

A capital plant for contrasting with it is the shrubby *Orache*, *Atriplex Halimus*, with pretty foliage covered with a silvery sheen, but it rarely flowers with us, and still more, seldom fruits, but it is freely propagated by means of cuttings. Both of these shrubs, if left to themselves, and not crowded together, form dome-shaped bushes, and are useful to decorate banks sloping to the sea. The *Mezereum*, *Daphne Mezereum*, also requires the fruit to be cleaned in this manner, and the seed sown at once in the seed-bed. This shrub has a trick of germinating so unevenly that by sowing a large bed of it, the young plants will keep appearing for some months. Besides being a pretty, early, or winter-flowering shrub, it quickly makes a stock for *Daphne indica* and other evergreen species, and some of the seedlings should be potted for inside grafting. But though so used, it is not a permanent stock, for being deciduous, the majority of the evergreen *Daphnes* do not take kindly to it, and it is preferable to make use of the *Spurge Laurel*, *Daphne laureola*. Some of the fruiting shrubs are best raised from "potted" seed, which process was described in treating of raising the Hawthorn and other trees from seed. *Experience*.

(To be continued.)

GATESIDE.

THE country residence of Mr. McQueen is situated in the parish of Dryman, at the base of the southern slope of Ben Lomond, and within a short distance of the queen of Scottish lakes, on which the steamers, with their freights of tourists from all parts of the civilised world, can be seen passing to and fro. The house was built by its present owner about nine years ago.

Being built with the red sandstone of the district, it harmonises well with the purple Heather on the side of the mighty Ben during the months of July, August, and September. And to the casual visitor it seems rather strange to be standing amongst plants brought from all quarters of the earth, and admiring the progress they have made; and to see how in a short time man can change the aspect of almost anything. And yet within a stone's throw of all this grandeur the wild Heath is going. And should you turn your face towards the north, there before you is some of the wildest scenery in Scotland, right in front is Ben Lomond; and to the right is Ben Venue; then, a little further east is Ben Ledi and Ben Aon; while to the west can be seen the far-famed pass of Balmaha, where, when once through, Rob Roy and his followers considered themselves safe from their natural enemy, the Duke of Montrose, when they had been helping themselves to some of His Grace's grain or cattle, or relieving the factor of the rents collected for the Duke.

On entering, at the main entrance off the Gartness Road, one immediately conceives the idea that one is about to see something of no mean order. On each side of the carriage-drive is a fine row of Lime trees, about 24 feet back from the gravel. Then in front of that is an assortment of Conifers, with a nice, well-kept verge of grass in front. On winding our way up the drive, we were fortunate to meet Mr. George, the enthusiastic gardener, who gave us a hearty welcome, and then proceeded to show us over the place. We first visited the glasshouses, and the first two we entered were devoted to zonal *Pelargoniums*, where all the finest varieties of the day are grown. It seems Mr. George's practice to obtain all the new varieties as they come out, and to weed out a corresponding number of old stock, with the result that his houses afford a treat worth going far to see. There were also some very fine seedlings raised by Mr. George. The Vines were carrying fine crops of Grapes. Muscats seem to do very well. The soil is a sandy loam, with a gravelly subsoil on the red sandstone.

*

FIG. 126.—LÆLIO-CATTELEYA, CLIVE.

(Lip maroon-purple, yellow at the base. From a plant exhibited by the Right Hon. J. Chamberlain. See p. 426.)

as by pheasants and other game birds, and plants may always be found in woods and a where it is planted. The nurseryman, however, trust to Nature to furnish him stock, and so the berries of both these plants are thered, and rubbed in sand to dispose of the seed skin, and the seeds are then sown in beds. The young seedlings should be transplanted as soon as large enough, this treatment being the same with *Mahonia*, as it makes coarse and woody roots, with little fibre, and transplants badly kept moved. *Berberis dulcis*, as well as the noble *Mahonia japonica* (Bealei), are raised from seed rubbed out in sand from the ripe fruit and either sown in pans or boxes, or directly in the open. The *Arbutus*, or Strawberry-tree, it gets to maturity, fruits freely in this way, and attains to the dimensions of a small

well as for the handsome scarlet-flowering variety, are worked. These require a practiced hand to graft, the bark being very thin; and it is safer to carry out the operation under glass.

All soft fruits require the same kind of treatment, as to divesting the seed of the surrounding pulp, and often tough skin, as it accelerates germination.

Among climbing plants, the Honeysuckles are best so treated, the sticky pulp being rubbed from the seed, and the latter sown without delay in propagating-pans or boxes.

Bupleurum fruticosum with foliage and flowers having the scent of Ivy, and when in blossom in the autumn attracting swarms of Hover flies and blue-bottles, fruits generally freely in the south and west of England, and can be easily raised from seed, which, if sown in the open ground as soon as ripe, will germinate the following year and the

fertile tracts, hedge-row timber and small woods are chiefly represented. These circumstances all aid in rendering our landscapes more attractive if properly attended to, for there is little doubt that a large plantation is more in keeping with the idea of extensiveness which a hilly country conveys than a small one. Small clumps of trees dotted about a hill-side without any apparent reason are never natural, and more often than not destroy those lights and shades which occasional elevations and depressions in the surface give to a hilly landscape when viewed from a distance.

On hill-sides plantations should either be sufficiently large to form a distinct feature in the land-

land inside the boundary fence, no doubt prevents planters from imitating Nature too closely in this respect, but a great deal may be done by a little variation in the species near the boundary. Birch, Willow, Juniper, &c., mixed with the larger forest trees, all help to form an irregular margin, and occasional spots left unplanted here and there, or planted only in a partial manner, assist in the same direction.

On flat ground, this breaking up of the margins, if less important in its effect upon the landscape in general, still improve the appearance of a wood considerably. It is easily effected by freely thinning the margins at an early age, and leaving clumps here and

star which directs their operations. If so, then let us have ornament in its highest sense, and give up the idea that the mere use of what the nursery trade has styled "ornamental trees and shrubs" for the sake of convenience, necessarily make an ornamental plantation or landscape. Indigenous forest scenery in Britain may not come up to that of many continental types in the opinion of many persons, but it has at least a character of its own; and it is useless to attempt to improve it by creating a mongrel form of scenery by methodically mixing it with species of a totally different type. In our opinion, plenty of room exists for ornament, profit, and sport in the woodlands of any average estate, but we cannot have all three treading on one another's toes, as is usually the case at present. Turnips and Potatoes are not usually grown in a flower garden, although the land devoted to both may lie within the same boundary-fence. In the same way, no difficulty exists in the way of growing ornamental trees (or groups of trees), game cover, and clean marketable timber on an area of 50 or so acres, but we must make up our minds as to the extent of ground we are going to devote to each at the start and keep to it. Character and variety are what we chiefly want in woods or anything else, and these cannot be obtained by mere chance or accident. *A. C. Forbes.*

(Concluded from p. 31.)

FOREIGN CORRESPONDENCE.

CHRYSANTHEMUMS AT STUTTGART.

THE great strides which the cultivation of the Chrysanthemum has made in Germany during recent years was particularly exemplified at the exhibition held at Stuttgart a few weeks ago, as also the great interest taken by all classes of the public in the same.

The number of visitors, including the Royal family, who paid the show a prolonged visit, was very large, and the same may be justly considered as one of the best and largest yet held in Germany.

The "Gewerbehalle," the centre of last year's industrial exhibition, with its large fountain, was, as if by magic, turned into a beautiful flower garden, the background and side-walls being decorated with Christmas Trees (Abies) and Palms; whilst in the body of the hall, as a relief to the vivid colours of the Chrysanthemums, six fine specimens of *Chamærops excelsa*, in tubs, about 10 to 12 feet high, with a small underground of Laurels and Euonymus, were introduced with great advantage.

On the whole the exhibits were good, especially those of Messrs. Pfitzer, Ernst, Ulrich, and Bofinger.

Mr. Ulrich, who has done the most in the last few years to popularise the Chrysanthemum in Stuttgart, must be placed at the head of the list of exhibitors, his standards, half-standards, and specimen plants, as well as cut blooms, being the nearest approach to the English ideas of any in the show. And then his floral arrangements (of Chrysanthemums only) from the hands of Mr. Aug. Herrmann, one of the best modern exponents of the art of wreath-making and floral decorating in Germany, were unsurpassed.

Mr. Pfitzer staged a grand collection of about ninety of the best varieties, old and new, affording the nurseryman and amateur ample opportunity of studying and comparing them as to habit and colour. His collection from summer-made cuttings, in about seventy varieties, with only one bloom each, consisting of mostly new sorts, was also very fine.

Last, but not least, I must particularly mention Mr. Bofinger's specimen plants, which were a relief to the many large-flowered varieties, by reason of their simplicity. He exhibited six or seven plants in tubs with crowns of 4 to 5 feet in diameter, with about 200 to 250 flowers each in bloom, grown as they would almost naturally grow, that is, without too much disbudding, and in the following old and newer favourite varieties, viz., *Source d'Or*, *La Triomphante*, *Admiral Sir T. Symonds*, *Wm. Seward*, *Gloire du Rocher*, and *Miss Gladys Routh*. Staged about 1 to 1½ foot from the floor, with an elegant

FIG. 127.—CATTLEYA EMPRESS FREDERICK VAR. LEONATA: HORT. VEITCH.
(Lip purplish-crimson, with orange veins. See p. 428.)

scape, or should be confined to hollows and ravines where their boundaries are obscured, or coincide with the margins of these natural depressions more or less closely. In any case, the margins of a hillside plantation should always be broken up as much as possible by throwing forward groups and single trees in advance of the main bulk of woodland. The boundaries of natural forest land illustrate what is referred to here better than anything, more especially where some indigenous species is spreading itself over a piece of waste land. In such a case, the outside trees are always smaller and more scattered than those towards the interior, and that clearly defined boundary line which so often marks an artificial plantation is always absent. A desire to make the most of the

there standing thick enough to form a striking contrast to the intervening openings and inlets. Such treatment is far more effectual than giving the boundary-line a circuitous or serpentine direction, which, of course, has no effect upon the light and shade alternations which are the chief beauties of a woodland margin.

If the above points were carefully attended to when planting and thinning British woodlands, the latter would prove to be quite as attractive a feature of landed estates as those parks and pleasure-grounds upon which so much attention is bestowed. When the unsatisfactory sylvicultural methods of British forestry are condemned, its advocates at once hasten to explain that ornament and not profit is the guiding

ground of *Dracœna*, *Kentias*, &c., their quiet, unassuming beauty struck every lover of flowers; it was a sight not to be forgotten, and found quite as much appreciation as any of the large-flowered—I had almost said, monstrosities!

Mr. Calvat, of Grenoble, also exhibited a collection of blooms of his this year's novelties, such as he intends to introduce next year. Of the former, Directeur Liebert, N. C. S. Jubilee, Baronne A. de Rothschild, and M. Hoste were very fine; whilst of the latter, the following seemed very promising, although all the blooms had suffered a little in transit:—*Madame Fossier*, very large, with broad white petals; *François Coppés*, amber-yellow, somewhat after the style of *Source d'Or*, with narrow, hanging florets; *Marie Calvat*, exceptionally large flower, of a delicate fleshy tint, very full, and with broad petals; *Madame Léonie Service*, white; and *Celeste Falconnier*, rose, were also good.

The varieties which have found the most distribution here, and which were staged in very fine specimens, are such all-round good sorts as *La Triomphante*, *Source d'Or*, *Avalanche*, *Admiral Sir T. Symonds*, *Nineveh*, *Wm. Tricker*, *niveum*, *Vivian Morel*, *Florence Davis*, *Wm. Seward*, *Chas. Davis*, &c., as well as a good many older ones, which are retained on account of their healthy and robust habits. With regard to the clean and healthy foliage of his plants, Mr. Ernst, who also staged a very good collection of the best of the older and newer varieties, obtained special commendation.

To summarise the best of the novelties staged by the various exhibitors, especially by Mr. Wm. Pfitzer, the following were universally admired:—*Madame Ferlat*, a beautiful incurved variety of a creamy-white colour, with very regular and close lying petals. *Secrétaire Fierens*, very fine Japanese, orange-yellow, with darker tips, and loose elegant florets—very large. *Mdlle. Lucie Faure*, extra, very large flower, pure white, similar in form to *Florence Davis*. *Beauté Grenobloise*, a very fine large incurved variety, creamy-white, slightly tinted in middle. *Madame Calvat* and *Madame Carnot*, both fine white large-flowering varieties, were also much admired. *Souvenir d'une Petite Amie*, a dwarf-growing variety, seems particularly suited for pot culture, ivory-white, and very free-blooming. *Madame Edmond Roger* seems to require a little more care in cultivation; it is of a peculiarly beautiful lemon-yellow colour, towards the centre green, and very free flowering—the flowers shown here were, however, rather too green. *Soleil d'Octobre* is a fine yellow, similar to *Miss Watson* in colour, with large full flowers and loose florets; an early sort. *Madame A. Brun*, very large, yellow-white, delicately striped with lilac, and very robust in growth. *Madame Bergier*, full large flower, with broad, loose petals; white, slightly tinted with lilac. *Surpasse Amiral*, golden yellow, at times lighter; large flat flower, striped red and brown. *Lago Maggiore*, very large and full, slightly twisted petals; a most beautiful yellow. N. C. S. Jubilee also obtained its full share of praise; whilst of other good varieties the following may also be noted, and should find a place in every collection:—*M. Ch. Molin*, amber-yellow; *Le Moucherotte*, bronze-yellow, gracefully incurved; *Isérette*, Inter-ocean, pearl-white, very fine; *Le Colosse Grenoblois*, enormous flower, fimbriated, somewhat similar in colour to the old superbe flore; *M. G. Chabanne*, canary-yellow; *W. H. Lincoln*, very fine yellow; *Rose Wynne*, delicate rose, extra; *Frau Commerzienrat Gruson*, orange-yellow; *Wanamacker*, the well-known American favourite, and *Calvat's Australian Gold*, which did not, however, show to much advantage.

Singles were very scarce, Ewan Cameron attracting the most attention, in beautiful compact plants, covered with flowers; the only others of this class of any merit, were *Purity*, *Silken Beauty*, *Mary Anderson*, and *Rafaelina Glüncke*, with large flowers, very loose pinky florets, and large yellow centre, of a very tall growth.

The above by no means exhausts the list of novelties and fine old sorts, for taste admittedly differ, but I think enough has been said to show that the exhibition was in every way well represented. *H. R. W.*

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

The Repairing of Fruit-walls.—The present mild weather offers a specially favourable opportunity to do any needful pointing and repairing of the fruit-walls. To neglect this kind of work when the state of the walls is getting worse yearly is to afford hiding places for a variety of insects which prey upon the fruit, young shoots, and the foliage. These evils are more especially noticeable on Apricot, Peach, and Nectarine trees. This is the only season when the trees can be unfastened, but there is the likelihood of the pointing being cracked and displaced by frost before the mortar has had time to harden thoroughly. This risk, however, may be lessened, if not altogether got over, by facing the new joints with Portland cement and gritty sand, in the proportion of two of the latter to one of the former, doing this part of the work in the forenoon, so that the cement may become hard, impervious to frost, before night sets in. In preparing for this job, first draw all the nails, if it is with these that the trees are secured to the walls, and lay the branches of each tree together in small bundles, fastening these to stakes driven into the border. Then, with a stiffish brush dab hot limewash into every hole and crevice, then make the joints good in the manner indicated. This kind of work is more conveniently done when it is spread over a series of years, the complete unfastening of the trees being an operation that takes much time, and the refastening still more time.

Wiring Walls.—The remarks made in the preceding paragraph may serve to remind—and probably convince—thoughtful readers of the *Gardeners' Chronicle* of the undesirability of securing trees to garden-walls by means of nails and shreds. Experience of both nailing and tying fruit-trees to walls, has taught me that tying is in every respect the better method. The initial cost of wiring walls, especially those used for Peaches, Nectarines, Figs, and Morello Cherries, is not heavy. Galvanised wire, No. 14 gauge, will answer admirably. The wires should be fixed horizontally at from 6 to 9 inches apart, running them through a series of eyes about 3 inches long driven into the joints nearly 2 inches, so that a space of about 1 inch intervenes between the wall and the wires so as to allow Peaches and similar fruits ample space to increase in size without coming in contact with the wall. The eyes or holdfasts (which may be purchased by the gross galvanised) may be driven into the wall at about 3 feet apart. If widths of 3 or 4-inch meshed, galvanised wire-netting—such as is used in poultry-yards—be tied over the horizontal wires used for Peaches and Morello Cherries, it will be found very convenient and suitable for training the numerous small shoots and branches to. I have always painted galvanised-wire two or three times before bringing tree or plant growth in immediate contact with it, with most satisfactory results. And this I strongly recommend readers to do who may contemplate wiring their fruit-walls.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

General Remarks.—For the next few months much vigilance will be required in maintaining the proper temperatures in the various houses; and as sudden changes in the weather are frequent, means should be taken to prevent any sudden changes occurring in the houses, or any disturbances of the proper degree of warmth and of aërial humidity; and undoubtedly the health of the plants depends, to a great extent, upon a carefully-managed night temperature. As artificially-heated air is injurious to the plants, fresh air should be admitted by opening the lower ventilators in the walls, and by damping the paths, &c. If the East-Indian-house is a dry one, a few evaporating troughs may be placed upon the hot-water pipes, and kept filled with water. One may, however, have too many of these troughs, in which case they become a serious evil; and if, on going into the house early in the morning, the foliage of any of the plants is seen to be covered with dew, it is a sign of excess of moisture in the air, which will, if persevered in, result in immature growth, "spot," and other evils. The hygrometer should always be in use in the winter to detect errors in regard to humidity in the houses. The East-Indian-house needs the larger amount of fire-heat to keep its temperature at the right point, and it should be well damped-down between the hours of 2 and 3 P.M., always saturating the ground

beneath the hot-water pipes at that time. Previous to damping-down, the warmth should be brought up to 65°; and at dusk, when the outside temperature generally falls a few degrees, the lower part of the roof should be covered with mats or some other thick material, fastened in some manner so as to prevent shifting during the night. A covering of this sort maintains the heat. The temperature of the house should be about 63° in the evening, and if the air has become dry, and it is thought that much fire-heat will have to be used during the night, the floors may be wetted again. The temperature at 6 A.M., if the weather be frosty, is better at 57° or 58° than at 65°. When at the lower figures indicated, more heat may then be admitted, and more moisture afforded. When the thermometer has risen to 63°, any plants in need of water may receive attention, and then, if the floors are washed or sprinkled, there will be sufficient moisture in the air to suffice till the afternoon. In the Cattleya-house, where the majority of the plants are resting, less atmospheric moisture is necessary, and a temperature of 55° or a little less is needed at night in cold weather. In mild weather a moderate damping of the floors twice or thrice a week will suffice, and in houses that are naturally damp, very little damping-down will be required. At the present time the Cattleya-house at Burford Lodge is kept at 60° by night, falling to 57° or 58° by the morning; the Mexican-house has an average temperature of 55°, and the air is kept rather dry. In the intermediate division, where there are grown *Epidendrum*, *Sobralia*, *Vandas* of the tricolor and suavis section, *Cologyne*, *Cymbidium*, *Miltonia*, *Platyclinus*, *Arpophyllum*, *Maxillaria*, the cooler-growing *Cypripedium*, as *C. insignis*, *C. Leeatum*, *C. Spicerianum*, *C. villosum*, *C. Boxalli*, *C. Shuhimi*, *C. Fairiesanum*, *C. Charlesworthi*, *C. venustum*, *C. vexillarium*, *C. Domini*, &c., the temperature is a degree or two below that of the Cattleya-house, and the atmosphere, in consequence of the plants requiring more water at the root than those, is moister. Where these plants cannot be accommodated to a house by themselves, they should be placed together at one end of the Cattleya-house.

PLANTS UNDER GLASS.

By G. H. MARCOCK, Gardener, Luton Hoo Park, Luton.

Gardenias.—In order to keep these plants in health, a constant war must be waged with mealy-bug and brown scale. If they are potted plants, let them be syringed or dipped at intervals of a fortnight in soap-suds at 95° of warmth, into three gallons of which a wineglassful of petroleum is poured. Plants that have heads of large size, and cannot for that reason be immersed in a tub holding but a few gallons of soap-suds, should be held on the edge by one workman, whilst another plies the syringe, observing not to let the stuff soak into the soil. Scale can be killed by immersing the heads in water heated to 140°, and held in it for a few minutes. It will not harm the plants, only it must be kept at that degree of heat by adding more hot water from time to time. This is good for all kinds of scale, and costs nothing.

Gloxinias.—If flower be required in the month of February, choose some of the tubers that have been the longest at rest; clear off the leaves, if any, take away the crust of soil for half-an-inch deep, replacing it with new loam, peat, leaf-mould and silver-sand; afford a slight watering, and set them near the light in the stove, Pine-pit, or forcing-house; syringe the soil and pots twice a day till the leaves start to grow, when no more water must be applied in that manner, but afford it to the soil only, and with a spouted can, in very moderate quantity at the first, till on turning out a few of the pots it is seen that root-growth has become active, and a greater quantity is needed at a time. In full leaf manure-water may be given to such unpotted tubers once a week with advantage.

Chrysanthemums.—The propagation of these plants may soon commence, the cuttings being selected from the best of the shoots springing from the roots, and those that have been the least crowded together. Place them in sandy loam and leaf soil in thumb-pots, and let the pots be plunged in fine coal-ashes or coco-fibre in hand-lights or bell-glasses inside of a low-roofed greenhouse. If much moisture condenses on the glasses wipe it off with a dry cloth in the early morning, and see that the soil in the pots does not become dry, airing the cuttings occasionally for half an hour.

Ferns.—A little more care should now be exercised in affording these plants water, which in mixed houses is not an easy matter, but much may be done to lighten the labour by arranging the various species

together in groups, as far as may be expedient. Most species of Ferns will bear a slight reduction of temperature up to the end of the month of February, and resting more or less is necessary to ensure a good growth by-and-by. Deciduous Ferns should be allowed to get dry if the pots are resting on a cool moist base, which is a rule applicable to *Davallias*, *Nephrolepis Bausei*, *Leucostegias*, *Lastreas*, *Osmundas*, and the pretty *Onoclea sensibilis*. More names might be given, but these will serve as a guide to the cultivator. *Gleichenias* may be kept on the dry side. A temperature of 40° at night will safely carry resting Ferns of the coolhouses through the winter. Tree Ferns should be afforded a resting period, the wetting of the stems being discontinued, but the temperature for these plants should not fall below 50° at night. *Adiantum cuneatum* will bear a similar degree of warmth, only sufficient water being given as will keep the old fronds from shrivelling. *Pteris tremula*, *serrulata*, and *cristata*, will bear a temperature of 45° when kept drier at the roots, and plants which are treated in this manner will start away strongly in the spring.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maidenhead.

Fuchsias.—The cuttings that were inserted in September being rooted, may be potted singly in small and large 60's, if it is the intention to use them in bedding-out, and to keep them growing in an intermediate or stove temperature. Let them stand on a shelf near the glass.

Bulbs, &c.—Those bulbs which were planted in the months of October and November are pushing up leaves, and in some instances these are an inch above-ground. Daffodils and Jonquils being the most forward; and with a view to affording them protection in severe weather, place a mulch 2 inches thick of Cocoa-nut fibre refuse, spent Mushroom-bed manure, or half-rotten leaf-soil over the beds or round the clumps. It is seldom that the gardener can plant Roses and trees and shrubs at this part of the winter; and if these operations need completion, let them be pushed forward whilst open weather lasts. The Roses should be afforded a mulch of half-rotten manure when planted.

Cutting Evergreen Trees and Shrubs.—Some work of this kind may be done during the continuance of the mild weather. Laurel hedges and banks of Laurel may be cut back to the required height, not hacking the foliage, but sawing out the larger branches where requiring removal, and cutting back the smaller ones with a pruning knife or *secateur*. Hollies may be similarly treated, also *Cupressus Lawsoniana* and others forming hedges or screens that require some cutting into shape. At this season the trimmings of such shrubs are frequently in request for church and house decoration, and the cutting may be made to serve a two-fold purpose. As far as Hollies and berried shrubs generally are concerned, there is a decided scarcity of berries in this district, and very little berried Holly will be procurable for Christmas decorations this year.

Planting Lily Bulbs.—Lilies should be got into the ground without loss of time; and as the bulbs are now arriving from abroad, orders should be given for them, the first customers getting the pick of the same. The soil for Lilies should be moderately light, and well drained; or a special compost of turfy loam, leaf-mould, and sand should be prepared to plant them in. Put the bulbs 4 inches to 6 inches deep, according to size, placing five or six bulbs in a clump, and bed each firmly on its base, and make the soil firm about and above it. The Tiger Lily is very effective, and the bulbs cost but little; the same remark applies to *L. testaceum*, *L. longiflorum*, *L. dahuricum*, *L. croceum*, *L. candidum*, &c.

General Remarks.—The bedding *Pelargoniums* should be watered very sparingly for some time to come, more especially in rainy or foggy weather, and the cooler the house or pit be kept the less the quantity of water required. An ordinary greenhouse temperature, or a minimum of about 45°, with air afforded every day when the weather is favourable, will carry the bedding *Pelargoniums* safely through the winter months. Damp is the worst foe to them, but its evil effects may be minimized by warming the hot-water pipes or flues occasionally, if their aid be not required to keep out frost. *Coleus* and *Iresines* require a temperature higher than that of the cold greenhouse in winter, a minimum of 55° being afforded. If the plants are growing much, the tops should be nipped out; and if stock be required, these tops may be inserted in small pots filled with sandy soil, standing the cutting-pots in a forcing-house.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, late of Eastnor Castle, Leicestershire.

Cucumber-house.—The bearing-plants will require continuous attention if the supply of Cucumbers is to be equal to a constant demand for them; and in order not to use the energies of the plants in building up deformed specimens, look over them twice a week, removing all such whilst still very young, spent foliage being also removed at such times. Let the temperature remain steady at 65° at night, rising 10° by day with fire-heat, and more than that if the sun shines, affording a damping-down twice or thrice a day, according as little or much fire-heat is employed. Avoid hard firing in cold weather; rather let the temperature drop 5° than encourage red-spider. The surface of the beds or mounds should be loosened, and light warm top-dressings afforded. The bottom-heat should be kept at about 80°, and when the soil is in need of water, afford sufficient to moisten it throughout. If a dung-bed frame is available, some Cucumber seeds may be sown; the plants are sure to come in usefully to fill up gaps in the houses or plant a new one.

Tomatoes.—Let the shoots be tied thinly over the trellis, and thus expose the fruits to the sun, and afford a temperature at night of 60°, with a rather dry atmosphere, otherwise disease may show itself. If the quantity of fruit is a good one, some liquid-manure should be applied; but do not afford moisture at the root before it is really necessary. Fruit should not be kept on the plants after it is perfectly coloured. Let the plants for spring-planting stand where they will grow sturdily, that is, close to the glass in a warm house, not crowding them together, and affording air in moderation to them whenever it is safe to do so. Should there be no such young plants, a few cuttings may now be made and inserted in pots of sandy-soil, and plunged into a brisk bottom-heat. These will fruit earlier than seedlings, and it is the proper course to take when seed of any special variety is scarce. Seeds may now be sown and soil warmed in readiness for pricking off the seedlings. Let everything be brought inside of the Tomato-house, pricking off the seedlings there, so as to avoid checking growth by chilling the plants ever so little.

Strawberries.—The earliest of the forced plants will now have fruits formed, and will stand in need of manurial aids, which should be afforded in light doses. Keep a night warmth of 60°, and drive the plants moderately by day, say with sunshine at 70° to 75°, affording a small quantity of air whenever it is prudent to do so, even at night, in lessened amount in mild weather. Place more plants in the starting-pit, shifting a batch thence to the forcing-house; and pay particular attention to the plants in the early stage, giving a bottom-heat of 75° to force up the bloom, and not much (if any) water before that has shown itself, or leaf-growth only or blindness may occur. If a hot-bed of leaves is the vehicle of warmth, the moisture thrown off by fermentation will prevent the soil in the pots getting quickly dry. Never quite close the lights, even at night, so that vapour can escape. The plants may be plunged at not further from the glass than 1½ foot.

THE APIARY.

By EXPERT.

Feeding Back Extracted Honey.—Question: I have read somewhere that if I were to run an apiary for extracting honey during the harvest of white honey, and feed the same back to the bees to put into sections, said extracted honey would sell in the section form at a price that would give me a big profit. Is this a fact? If so, how and when should extracted honey be fed back in order to procure comb-honey?

Answer: The feeding of extracted honey in order that comb-honey may be obtained, is something that has been tried by very many of our best apiarists, and still remains an unsolved problem with some of those who have tried it. Some have reported success, and others a failure, but if I am correct, those who consider the thing a failure far outnumber those who consider it a success. From my experience in the matter, I should say if anyone must feed extracted honey to his bees, in order that comb-honey may be produced, it should be fed in the spring, in order to hasten brood-rearing, thus securing multitudes of bees in time for the honey harvest; then, by putting on the sections at the right time, a large crop of comb-honey may be secured, if the flowers do not fail to bloom, or to yield honey. My experience has also led me to think that it is better to secure the honey in the sections in

the first place, rather than have it stored in combs, and then thrown out with the extractor, that we and the bees may go through much labour and stickiness in order to secure the same thing which we might have secured without all this trouble. The practice of feeding back is on the principle of producing two crops to get one, and no one would argue that such a course would pay in the long run. Even under the most favourable circumstances, to finish nearly completed combs of honey, I cannot make it pay if I count my time as anything. At the close of certain seasons when I would have a large number of unfinished sections, many of which were so nearly completed that a few ounces of honey would apparently finish them, it seemed that it may pay to feed a little extracted honey to finish the same; but after a careful trial of the matter, covering a period of ten or more years, I finally gave it up as a bad job, and have not fed back a pound of honey during the past six years. If anyone should wish to satisfy himself that feeding-back will not pay, he can get the best results by feeding the extracted honey right at the close of the early white-honey harvest, so that the bees are kept active. It is thought best by some bee-keepers to take away all combs except those which have brood in them, when preparing the colony for feeding back; but if all combs are filled with sealed honey, except that which the brood occupies, there is no advantage in taking away the combs that I can see. The extracted honey should be thinned to a consistency of syrup by adding the necessary amount of warm water, thinning only the amount needed for one feeding at a time, for if the thinned honey is allowed to stand long in warm weather, it is quite liable to turn sour and be spoiled. From "Gleanings."

THE KITCHEN GARDEN.

By W. H. POPE, Gardener, Highclere Castle, Newbury.

The Root-store.—In bad weather, when the gardeners cannot be employed out-of-doors, the opportunity is afforded of making an examination of the roots stored in cellars and other places, removing those that have begun to decay, removing the growths from Potatoes, and generally sorting everything over. There are certain roots which, if not allowed to make a little growth, will rapidly decay, viz., *Salsify*, *Scorzoneria*, *Beetroots*, *Turnips*, *Kohlrabi*, *Paraleys*, and *Celeriac*. Such roots should not be thrown higgledy-piggledy in a heap, but be arranged in sloping banks of damp soil or sand, with the butt-ends protruding; and if a little light can be afforded, so much the better. They would grow if they were not bedded in sand, &c., but the result would be deterioration.

Onions.—The bulbs in the loft, or hanging in sheds, should also be examined, and any that are decayed or making leaf-growth removed. Onions are keeping uncommonly sound this year. Specimen bulbs reserved for bearing seed may now be selected, and planted on a piece of rich, well-prepared ground, in a warm spot, setting them with the tops just showing at the surface. The bulbs should have a slight mulching of litter in case of hard frost setting in. If more than one variety is planted, let the varieties be as far removed from each other as possible.

Preparations for Forcing.—The time is approaching when the forcing of Carrots, Potatoes, Radishes, &c., must be undertaken, and due provision should forthwith be made by collecting materials for forming the beds. These may consist of tree-leaves and stable-dung, or a mixture of the two. In any case, the materials must be fermented, to get rid of the rankness that is inseparable from quite fresh materials, especially stable-dung. If leaves and dung are used, it should be in the proportion of one of the latter to three of the former. Straw cow-manure will answer in the place of horse-dung, and all should be well mixed together, and thrown into a heap to ferment, turning it once or twice before making up the beds. Hot-bed-making has, however, been described here so often, that it is hardly necessary to say more than that the beds should be firmly and compactly built, be about 3 feet thick at the back, and sloping slightly towards the front, and allowed to settle somewhat before putting in the soil. An important point is a suitable soil, and means should be taken to get a sufficient quantity stored in readiness where it can be protected from the weather. Potting-shed refuse, which is available in most gardens, answers well for the surface, whilst a light rich garden soil will do for the staple, adding a third of leaf-soil, and a good sprinkling of wood-ashes, the whole being thrown together in a heap, and well mixed together a week or two before it is made use of. If shed-room cannot be spared for this, it should be well covered up with boards, &c., to throw off w

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, and as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, DEC. 25—Christmas Day.

SALES.

MONDAY, DEC. 30 { Border Plants, Bulbs, and Roots at Mr. Stevens' Rooms.

TUESDAY, DEC. 21 { Special Sale of Orchids in Flower and Bud, at Protheroe & Morris' Rooms.

WEDNESDAY, DEC. 22 { Lilies, Tuberoses, Azaleas, and other Plants from Belgium, Roses, Begonias, &c., at Protheroe & Morris' Rooms.
Rose and Fruit Trees at Mr. Stevens' Rooms.

THURSDAY, DEC. 2 { Border Plants, Palms, Shrubs, Bulbs, &c., at Mr. Stevens' Rooms.
Border Plants, Bulbs, &c., at Mr. Stevens' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—39°.

ACTUAL TEMPERATURES:—

LONDON.—December 15 (6 P.M.): Max., 53°; Min., 45°.

PROVINCES.—December 9 (6 P.M.): Max., 53°, Scilly; Min., 40°, Bournemouth.

Weather stormy, mild; light frosts.

Chrysanthemum Sports. THE mystery attaching to sports is as great as ever, and as interesting to cultivators as any physiological subject. For all that, Chrysanthemum-growers were conspicuous by their absence at the meeting of the Royal Horticultural Society on Tuesday last, or, if present, they remained silent. Nevertheless, several of them had previously furnished particulars, of which the lecturer, the Rev. GEORGE HENSLOW, contrived to make good use. Mr. HENSLOW had received about 100 sports of one kind or another, from which he was enabled to frame the following percentages. The number is, of course, too small to place implicit reliance upon; but, no doubt, now that the matter is started, additional evidence will be forthcoming:—13 per cent. showed a change from a light to a deeper yellow; 9 per cent. sported from red to a deeper red; 13 per cent. from red to bronze; 10 per cent. from red to white.

More interesting than the mere percentages obtained, at least, until the experiment has been made with greater exhaustiveness, is the information that in no case has Mr. HENSLOW found a yellow-flowered variety to sport to red. As a probable explanation of this, it was mentioned that the colouring matter in yellow blooms is granular, while in all the rest the pigment is liquid. Neither has a true yellow changed to white, so far as the enquiry has gone; but once has changed to white, in the case of the *W. Tricker*.

green-flowered sports (virescence) are to be met with in the light of a reversion to the condition, other examples of which are given by the green Rose, the green Dahlia, &c. In the case of the green *Ixias*, however, Prof. HENSLOW has ascertained that the green colour

is not due to chlorophyll, but to a modification of purple.

Some varieties are much more unstable than others; thus among incurveds, Queen of England, Empress of India, &c., have given quite a number of sports. Some of the Japanese varieties, too, have "sported" before the seedlings themselves have been long in cultivation. Vivian Morel, for instance, has already given Chas. Davis, Ethel Amsden, and Lady Hanham, at least, and the variety itself is tolerably new. Much of what Prof. HENSLOW said regarding the greater tendency of certain varieties to sport, may be explained by ascertaining the length of time they have been in cultivation. Thus, Queen of England and Empress of India have naturally produced a considerable number of variations, whilst many sorts are discarded before their capacity for change has had time to fully develop itself. This circumstance, and others of a similar character, prevent, at present, any conclusions from being absolute. Many sports are not preserved because they are of no commercial value, but if these were all registered, they would doubtless effect a modification of the analysis.

Another and most extraordinary phenomenon is the simultaneous appearance of the same sport in widely-separated localities; thus, the same sport occurs at the same time in this country, in Belgium, France, or Germany. The only possible explanation is, that the cuttings were all derived originally from the same stock; but this explanation will, we fear, not cover all the cases.

In the case of species and varieties, which have been cultivated from time immemorial, like Chrysanthemums, Roses, and Carnations, crossing, designed or accidental, must be of common occurrence, so that each plant is, as it were, a compound of many elements derived from other varieties. If, we suppose that for some reason which we cannot explain, these mixed components become separate or "dissociated," we may fairly infer that sporting in those plants is the result of the dissociation, but this dissociation, though as we believe, a feasible explanation in the case of Chrysanthemums, does not hold good in other cases, and so we are left—guessing.

The accumulation and organisation of evidence such as Mr. HENSLOW has got together will doubtless do much to clear up much that is mysterious.

One point we should like to emphasise is this, that so far as we know, sporting in the sense of bud-variation does not occur in annual plants. The approximately complete absence of resting buds in these plants will not account for the absence of sporting branches or leaves (we are not speaking now of the flowers). A visit to a trial-field of China Asters and Sweet Peas will suffice to bear out our assertion. Moreover, we have at various times been favoured with the opinion of Messrs. CANNELL, Messrs. DOBBIE & Co., and ECKFORD, who in response to our enquiries, have assured us that in the plants named they have not encountered a bud-sport apart from seedling-sports. The absence of sports in such plants is probably due to the fact that their life-history is too brief for the purpose.

In any case, this is one of those instances in which the growers, having the plants constantly under observation, can furnish most valuable facts for the physiologist to digest, and which facts must, in the end, prove of practical value by the introduction of a degree of certainty where now haphazard conjecture reigns almost supreme.

Principles of Plant Culture.

THE professor of horticulture in the University of Wisconsin has prepared for the use, in the first instance, of his own pupils, and subsequently of others, a little volume, which appears to us well suited for the purpose for which it was intended. The earlier chapters are devoted to "the round of plant-life," beginning with the process of germination, and ending with the gathering of the seed. Speaking of the formation of flower-buds, the author says:—"Plants form flower-buds only when they contain reserve food. Rapidly growing plants rarely form many flower-buds, because the food is used up in growth as fast as formed. Checking such rapid growth by removing the growing points of the stem or root, or by withholding water, results in an accumulation of food, and is often followed by an abundant formation of flower-buds. Obstruction of the rootward current of assimilated food, as by ringing, causes an accumulation of food above the obstruction, and is often followed by the formation of flower-buds in that part. Again, "A water-supply insufficient for rapid growth may suffice for abundant assimilation; thus . . . florists often bring their plants into bloom at a desired time by withholding water. The flower-buds of most outdoor plants are formed during the drier part of summer, when a restricted water-supply prevents rapid growth, but when abundant sunlight and fully-expanded foliage, favour assimilation. We may infer, therefore, that treatment that favours the accumulation of reserve food promotes the formation of flower-buds—a proposition that is borne out by the experience of practical cultivators." The accumulation of reserve food is promoted by favouring assimilation—that is, by exposing the plants to the light, and air, and heat, by supplying sufficient root-food, and by ensuring a check to growth when desired, as by allowing the plants to become pot-bound, by withholding water, or pinching the tips of the more vigorous shoots.

The third chapter deals with plants as affected by unfavourable conditions, such as excess or defect of heat, water, light, or food, and with the means of preventing or minimising the evil results occasioned.

Another chapter is devoted to the methods of propagation, the methods being described and the conditions of success or failure pointed out.

A similar plan is followed in the case of transplanting and pruning. We can not say the author is more successful in his account of the rationale of root-pruning than are other people; the explanations usually given being contradictory. The last chapter is devoted to "Plant Breeding." In the appendix is given a syllabus of laboratory work so arranged that each pupil, so far as practicable, is required to perform for himself the experiments mentioned in the book, and to practise the various methods of digging, pruning, propagating, and the like. The book is a very useful one for the student, and we should be glad to see it introduced here. At present, it can be obtained from the author, but any foreign bookseller could procure it.

OUR ALMANAC.—According to previous practice, we shall issue a *Gardeners' Chronicle Almanac* with our first issue in the New Year. In order to make it as useful as possible for reference, we shall be obliged if Secretaries of Horticultural, Botanical and allied Societies, or any of our correspondents, will send us immediate intimation of all fixtures for 1898.

* An elementary treatise designed as a text book for beginners in agriculture and horticulture, by E. S. Goddard (Wisconsin), published by the author.

THE ROYAL BOTANIC SOCIETY'S SCHOLARSHIPS.—We learn from *Nature* that the London Technical Education Board will proceed in July next to award three junior scholarships in practical gardening, which will be tenable at the new School of Practical Gardening which has recently been opened at the gardens of the Royal Botanic Society, Regent's Park. This school has been established with the view of providing a complete course of instruction for lads who desire to become gardeners. The scheme of work, which has been drawn up by the Royal Botanic Society, combines thorough practical in-

the Crystal Palace, and £162 at Norwich, fractions of a pound being omitted in each case. The report of the committee is given in another column.

SOUTH-WEST CHINA.—An extract from a letter of Dr. HENRY, published in a recent number of *Garden and Forest*, announces the discovery of a magnificent Paulownia with evergreen leaves, "which is the most gorgeous sight when in flower imaginable." *Lonicera Hildebrandiana*, discovered by General COLLETT in the Shan States, also occurs in China, and bears flowers of a deep yellow colour, and

C. Spicerianum, and the hybrids *Harrisianum* and *Wallacei*. Amateurs who possess but little "hot-house" accommodation for their plants, may obtain a hint from this.

RENFREWSHIRE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—The usual fortnightly meeting of this Society was held in Yields Hall, Paisley, on the 8th inst. Mr. ROBERT GALLACHER, Craigends, in the chair. There were two subjects for this evening, the first being a paper on "Draining, Road-making, and Levelling," by Mr. JAMES WALKER,

FIG. 123.—A BED OF *YUCCA FILAMENTOSA*, IN MESSRS. JACKMAN'S NURSERY, AT WOKING, SURREY.

(Flowers ivory-white, making the plant very effective when planted in masses. It is particularly suited for planting on rockwork and rugged ground.)

struction in all the operations of gardening, with theoretical instruction in botany, and the nature of soils and manures. The course is arranged so as to extend over three years.

MR. J. B. CARRUTHERS.—We learn from the *Journal of Botany* that this gentleman has just started for Ceylon, where he has been commissioned by the Planters' Association to undertake investigations into plant diseases.

NATIONAL ROSE SOCIETY.—A copy of the balance-sheet presented to the annual meeting on the 9th inst., showed a balance at the bankers' of £39 18s. 7d., after payment of all expenses. The prizes amounted to £89 at Portsmouth, £243 at

about 7 inches in length. *Leucosceptrum canum*, of Northern India, is a remarkable labiate, forming a tree some 20 feet in height, and in habit like a *Buddleia*.

CYPRIPEDIUMS IN COOL-HOUSES.—A capital illustration of the possibility of cultivating with success many of the *Cypripediums* in a comparatively cool temperature, was furnished by an exhibit of ten baskets full of plants from Messrs. GEO. PAUL & SONS, Cheshunt, at a meeting of the Royal Horticultural Society on Tuesday last. These plants had been grown in a Camellia-house, where the temperature falls to about 40°, occasionally below. They had short, thick, healthy-looking leaves, and were well flowered. There were five varieties of *C. insigne*, also

Hawkhead. Mr. WALKER is an acknowledged authority in the district on such matters, and fully upheld his reputation by the able manner in which he handled the subject. The second paper came from Mr. MCKINNON, Kilnside, on "How Plants obtain their Food," in which he explained his subject clearly, in a terse, concise, and able manner. Both papers were much appreciated, and several members took part in the discussion which followed.

EDINBURGH SEED TRADE.—The third annual dinner of the assistants was held on Thursday evening, 9th inst., in the West End Café. Mr. W. MACKINNON (Mr. J. DOWNIE's) presided over a large attendance, and the employers were strongly repre-

sented. A capital programme was submitted, several professional musicians contributing greatly to the success of the gathering.

POTATOS IN AMERICA.—From the most recent reports on the 1896 crop of so-called Irish Potatoes, we learn that the average yield per acre is 64'6 bushels, against 86'8 bushels in November of last year, 100'7 in the preceding year, and 76'9 bushels—the average for the last fifteen years.

MEXICAN PLANTS.—Dr. J. N. ROSE, of the United States National Museum, has lately returned to Washington from a five months' botanical expedition through Mexico, bringing with him a collection of more than 1500 species. Most of the collecting was done in the States of Durango, Zacatecas, and Jalisco, and in a region which, it is said, has never before been visited by a botanist. *Garden and Forest*.

UNSEASONABLE FLOWERING OF PLANTS.—A correspondent resident at Evesham, kindly sends us a list of plants in flower last month, supplied to him by A. H. MARTIN, Esq., M.D., also residing in that place. The entire list is too lengthy for our available space this week, but we may indicate just a few of the 136 species and varieties given, viz., *Petunia hybrida*, *Lilium auratum*, *Helichrysum*, Sweet Peas, *Begonia*, *Leptosiphon*, *Agapanthus umbellatus*, *Sedum spectabile*, *Salpiglossis*, *Ageratum*, *Glaadiolus*, *Zauschneria*, *Heliotropium*, Love-lies-Bleeding, *Pyrus japonica*, *Arbutus Unedo*, *Kerria japonica*, *Coronilla glauca*, *Hydrangea*, *Abutilon*, *Tigridia*, *Choisya ternata*, *Cosmea*, *Berberis Darwinii*, *Iris alata*, *Lobelia fulgens*, *Heuchera sanguinea*, St. John's Wort, a sufficiently comprehensive, if much abbreviated list of plants, many of which are usually cut off by October frost. From a Dover correspondent we have a further list of forty-eight names of plants in flower at Buckland, and in Connaught Park, Dover.

PRESENTATION TO MR. W. H. HAMMERTON.—Advantage was recently taken of the occurrence of the annual dinner of the "Folkestone Amalgamated Gardeners' and Chrysanthemum Society," to present the Acting-secretary, Mr. W. H. HAMMERTON, with a purse of money, and an address expressive of the appreciation of his work by the members. The presentation was made by the Mayor, and it was all the more pleasant to the recipient because so unexpected. Mainly through the exertions of Mr. HAMMERTON, a successful exhibition of Chrysanthemums has been established at Folkestone.

CULTIVATION OF MELOCACTUS HUMILIS.—In the number of *Nature* (November 25), in the report of a meeting of the Amsterdam Royal Academy of Sciences, Professor SURINGAR is mentioned as having "presented a fifth contribution to the knowledge of the *Melocacti*, as a sequel to previous papers." The author showed the skeleton and a photograph of a specimen of *Melocactus humilis* from Venezuela, described by himself in 1889, and seeds of which he sent at the time to the firm of DAMMANN & Co., near Naples. It seems that the culture of this plant, which does not succeed in hothouses in North and Middle Europe, might be tried with advantage in the sunny climate of the South Italian coast, exposed to sea-winds. Professor SURINGAR exhibited a live specimen, now seven years old, raised from the seed by the above firm, and which has already blossomed and borne fruit. With the exception of a slight difference in size and shape, the mother and the daughter plant are very similar. In the colony itself, too, the culture will be tried, that it may be possible to send culturable specimens over from there without detriment to the natural flora. The author exhibited photographs, and gave a description of five new genera, received from Curaçao. These specimens, which have developed plants in tolerably large numbers the latter, will be sent back to with those of some known genera, time and determined in Amsterdam, so that the seedlings will at their own names. In conclusion, the

author presented for inspection the first part of the *Iconography*, announced some time back, and published by the firm of E. J. BRILL, at Leyden, as the third volume of the *Musee Botanique*, and entitled *Illustrations de Melocactus*, with reproductions of photographs and coloured plates of the thorns, flowers, and fruits."

PRESENTATION.—On November 22, Mr. J. T. ECCLESTONE, F.R.H.S., who has been appointed Head Gardener to T. P. WOOD, Esq., Brambling House, Chesterfield, was the recipient of a handsome clock, presented to him by the gardeners under him on his leaving Canwell Gardens, the seat of A. B. FOSTER, Esq., where he has been Head Gardener and Forester for a period of eight years.

THE GERMINATION OF CONIFER SEEDS.—A great difference exists in the germination of conifer-seeds from different localities. The seeds of all the conifers hardy in the eastern States of America come up at the same time or nearly so. Norway Spruce, White Spruce, Scotch, Austrian, and Mountain Pines, the Colorado conifers, *Picea pungens* and *P. Engelmanni*, Douglas Spruce, *Abies concolor*, and other common conifers can all be uncovered at one time. But few seedlings come up ten days after the first ones appear, while conifer-seeds from a warmer climate are very irregular in germinating. I raised a large quantity in California in 1889 and 1890. The kinds already named were sown in beds adjacent to the more tender kinds. *Pinus Jeffreyi*, *P. ponderosa*, and *P. tuberculata* started from two to four weeks before the others came up. *Abies magnifica*, *A. grandis* and *A. amabilis* came very scatteringly; the first of these appeared in April and the last in September, and they required careful attention. The various *Cupressus* varied as much as the *Abies*. Douglas Spruce, *Abies concolor*, and *Pinus ponderosa*, from Colorado, came up much more regularly than the same species from seed collected in California, but the seedlings from California-seed made much larger plants at the end of two years. Most of the seed from the Orient acted as those of our native and European species do, being very regular in germinating. The exceptions are *Picea Morinda* and *P. Ajanensis*, but as I had very little seed of the latter, and that apparently two or more years old, I may be mistaken in this particular. The seeds of *Sciadopitys verticillata*, *Cedrus Deodara* and *C. Libani* are also irregular in time of germinating. *Cedrus atlantica* may also be added to the list, but it comes up more evenly than the seeds of other Cedars. The seeds of our native White Pine are the most uneven in germinating of those of the hardy conifers; but although they sometimes come up irregularly, this tree can hardly be classed with the species which are irregular in germinating. *Thuja gigantea* and *Libocedrus decurrens* are irregular. T. H. Douglas, in "*Garden and Forest*."

THE AMATEUR HORTICULTURIST.—We all know how difficult it is in practice to define an amateur; schedule-framers, judges, and journalists, all blunder in turn over him. If we turn to our brethren in Canada, we find the directors of the Toronto Horticultural Society deciding that an amateur horticulturist is "one who does not depend or has not depended in any way for his living on any occupation connected with horticulture." A literal interpretation of this definition, however, would lead the reader to infer that one need have no connection whatever with horticulture, and yet be considered an "amateur horticulturist." This appears to be something of a paradox. But the directors have also furnished an addendum clinching their definition; they add, "and any person residing with or on the premises of one who so depends or has depended for his living on any occupation connected with horticulture is debarred from exhibiting." This embargo may have a local significance; but to an outsider it appears uselessly severe, and we are no "forrader" over here.

THE ARTIFICIAL PRODUCTION OF VARIATED LEAVES.—At a recent meeting of the Horticultural Society of Berlin, Garden-Inspector LINDE-

MUTH of that city suggested that it might be possible to produce variegated varieties of every species, provided that there be a form with coloured leaves in some way related to it, but not necessarily of the same species. His theory is based on his experience that if a variegated variety of one species is grafted on a green form of another species, and vice versa, the green plants produce variegated shoots. By way of proof, he exhibited *Abutilon Thompsoni*, fol. var., grafted on *Malvastrum capense* with green leaves, which, below the graft, had produced shoots with striped leaves. Again, he showed *Kitaibelia* species with green leaves grafted on *Abutilon Thompsoni*, fol. var., and thereby having become variegated. A cutting taken from this new coloured variety, planted in the open ground, had grown vigorously, and remained variegated. *Althaea officinalis* grafted on *Abutilon Thompsoni*, fol. var., became variegated. *Petunia hybrida* grows readily and vigorously if it is grafted on *Nicotiana glauca*.

"FLORIST."—It is evident from the annexed extract from the monumental English dictionary, published by the Clarendon Press, that the compilers have not succeeded in recording all the shades of meaning attaching to this word.

"Florist" (flōr'ist). [*f. L. flōr-, flōs flower + -ist. Cf. Fr. fleuriste, It. fiorista.*] One who cultivates flowers: one skilled in knowledge of flowering plants; also, one who raises flowers for sale, or who deals in flowers.

1623 Sir H. Wotton in *Reliq. Wotton*, 407 It hath given me acquaintance with some excellent Florists (as they are stiled). 1678 VAUGHAN *Thalia Rediv.*, To his Books 47 Choice Flow'rs, all set and drest By old, sage florists. 1718 *Free-thinker* No. 11 ¶ 7 She will watch... as a Florist does a Bed of Flowers in the Spring. 1808 *Pike Sources Misiss.* III, 210 This father was a great naturalist or rather florist: he had large collections of flowers, plants, &c. 1871 *EARLE Philol. Eng. Tongue* § 251 They differ as the flowers of the florist differ from those of nature."

The special sense in which a man is a "florist" or occupies himself with "florists' flowers," is not brought out, and, indeed, it would be difficult to frame a satisfactory definition. LITTRÉ is no more complete in his French Dictionary, for he does not indicate the common use of the term among his countrymen to signify a herbarist, collector or field-naturalist. On the other hand, he tells us that the word *fleuriste* is applied to makers of artificial flowers, whom we should never call florists.

FINE ARTS EXHIBITION.—In connection with the summer exhibition of the Antwerp Royal Horticultural Society to be held in July, 1898, there will be a section for pictures of plants, flowers, and fruits in oils, water-colours, pastels, &c. Artists of any country will be admitted.

A VETERAN EXHIBITOR.—M. HENRI VANDERLINDEN has, since 1858, never failed to take part in the Antwerp Horticultural Society's annual exhibitions. Next year it is proposed to celebrate the fortieth anniversary of his career as an exhibitor. In 1857, M. VANDERLINDEN built his first greenhouse. It is remarkable also that he has had in his service but two gardeners, the former of whom is now dead.

SALE OF CYPRIPEDEUM BECKMANI.—*Cypripedium Beckmani*, which did not obtain a Certificate of Merit from the Royal Horticultural Society, being judged identical with *C. bellatulum*, was recently sold for 400 francs.

CARDIFF AND DISTRICT CHRYSANTHEMUM SOCIETY.—The annual dinner of this Society was held on the 8th inst., at the Marchioness of Bute Hotel, under the presidency of Mr. FRED. G. TREBESER, when about fifty members and friends attended. The usual toasts were proposed and duly honoured. The recent show was the best as yet held by the Society, and the results were likewise better than in previous years, and a small balance remains in hand. The date of the show next year will be as near as possible to that of this year.

SCILLY ISLANDS.—It is said that the flower crops on the Scilly Islands are not so forward as they were last year, which was a record one, and the general opinion among the farmers is that the early

blooms will not be so prolific as last season. Various reasons are given for this, one being that the bulbs are somewhat exhausted after the exceptionally heavy crops they produced last year. It is to be hoped that good prices will compensate for any deficiency in quantity. Much has been done recently by the Great Western and the North-Western Railways to develop this delicate industry. New markets in the North have been opened up by a quick and improved service of fast trains, particularly the new night express from Bristol by the

made:—Certificates of Merit to Comte Joseph de Hemptinne, for *Oncidium crispum*, and for *Cypripedium Leeatum giganteum*; to M. Van Wassenhove, for *Kentia Belmoreana*; M. A. Rigouts (*à l'unanimité*), for *Vriesia Makoyana* and (*par acclamation*), for *Stenorhynchus speciosus* var. *maculata*; also for *Nepenthes coccinea* and *N. atrosanguinea* (both *par acclamation*). To M. A. Rigouts again, for *Ataccia cristata*, and (*par acclamation*) to M. E. Bedinghaus, for *Phyllaea ericoides*. M. A. Rigouts was awarded a Botanical Certificate for *Coccolopsochelys repens*, and

tion, Calvat's Gold, President Nonin, M. Gustave Henri, M. H. de la Blanchetais, Charles Davis, N. C. S. Jubilee, Souvenir de ma Petite Sœur, Lord Brooke, Edwin Molyneux, Reine d'Angleterre, George W. Childs, Beauté Grenobloise, and Mrs. C. Harman Payne. The exhibits are to be so staged as to admit of their being carefully examined by the jury. The 1st prize will be a gold medal (150 francs) offered by Baron Ed. Osy de Zegwaart, Governor of the Province and President of the Society; the 2nd prize a gold medal (75 francs), the 3rd prize a medal (50 francs).

FIG. 129.—MARATTIA BURKEI: TREE FERN. (SEE P. 425.)

Severn-tunnel route, in direct connection with the up night mail from Penzance. Consignments leaving the islands in the forenoon are in the Liverpool and Manchester markets as early as six the next morning, at Edinburgh and Glasgow by midday, and at such a distant station as Aberdeen at six o'clock on the evening of the following day.

CHAMBRE SYNDICALE DES HORTICULTURE BELGE.—On the occasion of the meeting, on December 5, of the Chambre Syndicale des Horticulteurs Belges and of the Société Royale d'Agriculture et de Botanique, at Ghent, the following awards were

M. A. Toeffaert Honourable Mention for *Cypripedium* var. The jury expressed a wish to see, on some future meeting, *Cattleya striata*, exhibited by M. Van Wassenhove.

A BELGIAN CHRYSANTHEMUM COMPETITION.—The Antwerp Royal Horticultural and Agricultural Society propose to hold, next year, from November 12 to 14, a Chrysanthemum show, one section of which deserves special mention. For this are to be entered twenty specimen-plants of named varieties of Chrysanthemums, namely, Lincoln, Charles Shrimpton, M. A. Charmet, White Plume, Ma Perfection,

AMSTERDAM CHRYSANTHEMUM CLUB.—There is now a Chrysanthemum "Club" in Amsterdam which has lately published a catalogue prefaced by an article on the history and cultivation of this plant, by M. J. K. BUDDE, of the Utrecht Botanic Garden. It is he who introduced from Japan seeds of the Chrysanthemum indicum type—at least, so it is supposed. He sowed these, and a specimen grown by him from them was shown at the Amsterdam Exhibition. This enabled the actual forms to be contrasted with the primitive forms. M. DE LANGE, at Rotterdam, has held a very successful Chrysanthemum show. This afforded opportunities for testing the values of dif-

ferent manures; and Papillon, from M. A. CORDONIER, of Railleul, induced specimens with stronger stems, more vigorous and darker leaves, and finer flowers than were obtained by ordinary treatment.

PUBLICATIONS RECEIVED.—*Snap-Shots Christmas Number*. The same old pictorial Christmasy comicities, tales, and jokes, done up in an up-to-date style.—*Palmenzucht und Palmenpflege, &c.*, Von Dr. UDO DAMMER. We shall take an early opportunity of noting this book.

HOME CORRESPONDENCE.

THE LATE JAMES BATEMAN.—I may perhaps be permitted to add an interesting fact to the biographical sketch (*ante*, p. 400) of this distinguished and venerable horticulturist and orchidologist, who so recently passed away. When Sir William Hooker became editor of the *Botanical Magazine* in 1827, he instituted the practice of dedicating the yearly volumes to eminent botanists, horticulturists, and collectors. The first was dedicated to Robert Barclay, a patron of horticulture, who had a fine garden at Bury Hill, Dorking. Ten years later, in 1837, we find the same compliment was paid to the late James Bateman, in the following terms:—"To James Bateman, Esq., of Knyppesley Hall, Cheshire, author of the magnificent *Orchidacea of Mexico and Guatemala*, a work of which it is hard to say whether the beauty of the subjects represented, the execution of the figures, or the taste and judgment displayed in the typographical department, is most to be admired—the present volume is dedicated, with sentiments of high regard and esteem by his obedient friend and servant, W. J. Hooker." Sixty years is a long time to look back, especially in gardening, and more particularly in the history of the introduction and cultivation of Orchids. The first epiphytal Orchid figured in the *Botanical Magazine*, pl. 152 (1791), was *Epidendrum fragrans*, incorrectly named *E. coelestium*. This was regarded as a great curiosity, and its successful cultivation as a triumph of horticultural skill. A few years previously (1768), the great gardener of his day, Philip Miller, considered it futile to attempt to grow epiphytal Orchids. W. Bolting Hemsley.

THE ROYAL BOTANIC SOCIETY.—When issuing the schedule of prizes for 1897, the Royal Botanic Society of London inserted an additional regulation as follows:—"Successful competitors can obtain their prizes on the day of exhibition on application at the office after 5 P.M.—By order of the Council, J. Bryant Sowerby, Secretary." Can such a regulation be considered just when the successful exhibitors of 1896 have not yet received their prizes? Promises of "immediate attention" from the Society's office are renewed on application, but a request to be allowed to bring the matter before a meeting of the Council remains unanswered, although a stamped addressed envelope was enclosed for a reply. Also further attention called to the request. It seems scarcely possible such gentlemen as the members of the Council of the Royal Botanic Society of London could be aware of facts when they inserted the above unjust regulation, so far as previous exhibitors are concerned, at least, such is the opinion of *One of the Victims*.

BIG RED CABBAGES.—I have recently cut, in my master's garden, two heads of Cabbage, the joint weight of which was 5 stone 8 lb., the one being 42 lb., and the other 38 lb. *Sydney Harrison, gr., Hett Hills, Chester-le-Street.*

THE EVOLUTION OF THE BIG CHRYSANTHEMUM.—A comparison between the flowers of the wild type and the largest exhibition blooms produced by expert growers of Chrysanthemums, gives surprising results. Through the kindness of Mr. H. J. Jones and Mr.

Norman Davis, I secured large blooms of Madame Carnot (Japanese) and Mrs. R. C. Kingston (incurred); and, as representing the wild form, I took a flower of a small flowering seedling, which is the nearest approach we have at Kew to the dried specimens collected in China by Dr. Henry. I carefully weighed them and counted the florets in each, with the following results:—

	Type-like seedling.	Incurred (Mrs. R. C. Kingston).	Japanese (Mme. Carnot).
Weight of capitulum, including 6 inches of leafless stalk ...	½ oz.	8½ oz.	7½ oz.
Number of florets in capitulum ...	205	1053	1753
Length of longest florets ...	½ in.	3½ in.	7 in.
Width of florets ...	½ in.	½ in.	½ in.

In Madame Carnot the capitulum consisted of a large central receptacle, from which most of the florets sprang, but instead of its being naked when they were removed, it showed a broken, irregular mass of involucre bracts, which in the normal flowers are restricted to an outer whorl surrounding the plants. In addition to the florets which sprang from the receptacle, there were also numerous adventitious heads of florets developed in the axils of some of the bracts of the involucre proper. In other words, instead of a distinct plate-like receptacle, surrounded by a whorl of bracts, the involucre, and bearing all over its surface the florets, the whole capitulum was a confused mass of bracts and supplementary basal clusters of florets. From this it would appear that, by restricting the plant to one or two stems, and each stem to the production of only one head, the excess of organised food induces not only exceptional length and substance in the florets themselves, but also the formation of adventitious flower-heads, which go to increase the size of the whole. A great range of variety was revealed in the length of the tubes of the florets, and in the lobing or splitting of the flattened portion. Some of the florets were closed tubes for their whole length; others were closed nearly to the apex, whilst in other cases they varied. The lobes in some cases were almost horn-like. If this amount of variation occurred in other flowers than those of Compositeæ, we should be much surprised. These observations apply to only one bloom of a Chrysanthemum; how much more striking would be a comparison between all the many forms now in cultivation! One wonders how much further variation in the Chrysanthemum may be carried by breeders. W. W.

A HALL FOR HORTICULTURE.—All the controversy respecting the National Chrysanthemum Society and the Royal Aquarium tends to show what an ill-adapted and unpleasant place it is in which to hold horticultural exhibitions, and the disappointing amount of money the directors offer the Society compared with what is actually received at the turnstiles. This has been forcibly debated in the *Journal of Horticulture* recently, and such discussion is in my opinion most desirable, for the reason that there is at present no other suitable central place. It seems to me that the only remedy for future success is to set to and find a site, and erect a building, temporary or otherwise, so that the most ardent in horticulture may have full control according to our likes and means. The scheme for a horticultural hall, which I suggested several years ago, and similar to what is in existence in many cities in America and on the Continent, was most favourably received by the President, Council, and also the committee of the Royal Horticultural Society; thousands of pounds were promised, and this I sincerely hope still stands good. If I am not mistaken, one gentleman offered to give £5000 if a similar sum was subscribed by a certain time; but, unfortunately, just at that time financial matters in the world were unfavourable, and great depression in business existed, and it seems to me that the present time should prove to be a most opportune moment for the revival and carrying out of that or a similar scheme. If a powerful and influential committee was selected from the National Chrysanthemum Society, and if our highly esteemed president, Sir E. Saunders, could be induced to act as spokesman, offering our cordial support to the President and council of the Royal Horticultural Society, the whole matter could be discussed, and the feelings of kindred societies and the public generally be ascertained. The Rose, Carnation and Picotee, Auricle, Narcissus and Cacti Societies con-

tinue to hold their shows at the Drill Hall, and I feel sure the National Chrysanthemum Society would be received with open arms by the Royal Horticultural, and without that chartered body wishing in any way to exercise any control over its internal arrangements whatever. I am both willing and anxious to co-operate in assisting to bring something of the kind prominently before the public. Unity is strength, and it seems to me, if the united strength of all the kindred societies now existing in London could be secured, and if they would pay their proportion towards the interest on borrowed capital, if such a course was deemed necessary, there is no reason why we should not have a home of our own for ever, and not lodgings. I think we might reasonably count on something like the following income, each society, of course, taking its own gate-money:—

Royal Horticultural Society ...	£400 per annum.
National Chrysanthemum Society ...	200 "
National Rose Society ...	100 "
National Dahlia Society ...	100 "
Carnation and Picotee Society ...	50 "
Auricle Society ...	25 "
Cactus Society ...	10 "
Letting the Hall for horticultural business Committee meetings ...	100 "
Letting for other approved purposes ...	1000 "
	£1935

This at 4 per cent. gives a borrowing power of nearly £50,000. If the Council would favourably reconsider the suggestion, and all kindred societies would cordially support such or a similar scheme, it seems to me we can well picture Phoenix rising boldly out of its own ashes, and British horticulture going on in rapid harmonious strides. It certainly is an undisputed reproach that horticulturists do not possess in the City of London a building large enough to hold even an ordinary flower-show, and, in my opinion, it is now quite time we did. I ask one and all if the time has not arrived when this hall should be begun? H. Cunnell.

THE CHRYSANTHEMUM AND THE FUTURE TEMPLE OF FLOWERS.—It must be the hope of all horticulturists, considering the inadequate accommodation for floral displays in the metropolis, and among other things, just lately, for the Chrysanthemum in particular, that the realisation of a scheme for a common centre of the first order for horticultural exhibitions, should be achieved. It can indeed be only a matter of time when this idea, supported by the increasing number of Fellows of the Royal Horticultural Society, and the resources and initiative of this Society, will be put into practice in a satisfactory manner. I should also like to see, in reference to the Chrysanthemum, the tendency arrested towards ever larger and larger blooms, which are now approaching, if they do not already in some of the new varieties deserve, the term "monstrosity." The public taste for the encouragement of mere size, diverts beauty into a mischievous channel, and the craving for varieties of sensational size must soon pass the limits beyond which all claim to beauty is forfeited. It may only need a few years' further development for the result to be deplorable, and for a justly favourite flower to be rendered a thing of the past, as is already the case with many of the double-flowered tuberous Begonias. I only refer to this excessive size of blooms in order to propose that, instead of offering prizes to encourage their production, and the present fashion in showing cut flowers, a truer perception of perfection be supplied by some clever cultivator, as, for instance, by showing only plants in pots with, say, three blooms, or even more on each, at future exhibitions. The dwarf habit of some of the more modern varieties might be insisted on in regard to all future novelties, and these would lend themselves additional attractiveness to an exhibition. Certainly the exhibition of the blooms on the plants would require more space than the present method, which crowds the blooms far too closely. In this connection, the apparent abandonment of trained specimens of all types, either squat or pyramidal, with dozens of flowers on each, can hardly be defended. Were the necessity for exhibitions of increased space, and last—not least—light, thus to become a lever in the direction of the hall of the future, it might step into life, let us hope, with the new century now close at hand. Let us also hope that all the land suited to the purpose of a hall on the Thames Embankment is not yet bespoken. Although two attempts at combined action in the direction of the realisation of the scheme were made early in this and the previous year, the problem is still unsolved. Let us be a little

* Altou records both of these (*Hortus Kewensis*) as having been introduced in 1765.

superstitious, and predict the symbol "three" as of good omen. *H. H. R., Forest Hill.*

DIGGING THE ALLEYS RUNNING BETWEEN BEDS OF ASPARAGUS.—I am a grower of Asparagus in a small way only; still, I must take exception to your contributor on p. 399 of the *Gardeners' Chronicle*, who said "that the alleys may then be dug." The roots of Asparagus at Newbury must be very different to what they are here, for even when planted 3 feet apart the roots meet, and it is impossible to dig, and to attempt it with a spade would be, in my opinion, an act of Vandalism. He then writes as to raking off any rough portions that remain in March and April. Experience has taught me that Asparagus wants a covering of manure in summer far more than in winter; besides, the said heavy dressings must retard the growth in early spring, and most of us want it as early as possible. *J. K., Wimborne.*

ROSE CLOTH OF GOLD.—I was glad to see the note from "Wild Rose" concerning this beautiful variety. The error, whether of my pen or of the printer, which gave 15 inches as the diameter of the stem of a plant of Cloth of Gold was so evidently a misprint for circumference, that I did not trouble to correct it. Like "Wild Rose," I have seen this old favourite in grand form, and also scores of failures. There are no Roses that need more careful pruning than Cloth of Gold, Rêve d'Or, the Banksians, and other very vigorous growers. It is not so much on account of tenderness, as from the fact that all of our extra vigorous Roses flower upon the ripened wood of the previous season, and any of this which has passed through the winter is far too valuable to be cut away. Your correspondent instances a case where pruning was undoubtedly the fatal stroke to a grand old plant of Cloth of Gold. Upon a rectory in this neighbourhood is—or was, a few years back—a fine specimen; in the adjoining parish there still is a second plant growing in a very sheltered spot. This was the cellar of an old mansion, and is now turned into a Rose-garden. In the near distance the garden is completely surrounded by trees and specimen shrubs, several of which are among the finest in the country. With such shelter, plenty of light, and a good depth of loam, Cloth of Gold grows remarkably well; but, unfortunately, the gardener has only one system of pruning Roses, consequently the plant annually produces wood that I have many times envied him the possession of, but which is far too hardly pruned to bloom. The specimen I mentioned in your issue of November 20 as flowering well during the past season is upon the mill-house at Barcombe, Sussex. I never noticed the true Noisette form of Cloth of Gold so distinctly as in this instance, scarcely a flower being borne singly. Respecting the drooping habit of Maréchal Niel, I think this rather an advantage than not, as one can better see the beauties of its blossoms upon walls and the fronts of houses than if borne in the boldly-upright manner of Cloth of Gold when doing well. *A. P.*

CARNIVOROUS SLUGS.—The worm-eating slugs are very plentiful in a large walled-in garden near Bury St. Edmunds, and I have had many opportunities of seeing them at night. On warm, showery evenings, especially, they may be found crowding the gravel-walks, and the Box-edgings which border the latter; in fact, their habits as regards locomotion are much like those of other slugs. Some few years ago I brought away one evening from the garden in question—which, by the way, is remarkably free from worms—more than half a peck of the slugs, and turned them down in the kitchen-garden here; but I regret to say, that of these or their progeny I have scarcely seen any since; probably they may have wandered into the shrubberies and long grass and got lost, there being no walls round the garden into which I put them to keep them at home. *J. C. Tallack.*

MUSCAT OF ALEXANDRIA SPORTING.—It is to be hoped that the recently mentioned sport from this Vine, which has appeared at Chiswick, will prove more amenable to treatment than a similar one which I had here until within the past year or two. In 1888 I planted a house mostly with this variety, and cut the young Vines down to within 1 foot of the soil, after which they were taken up as single rods in the usual manner. In 1892 I allowed one of these Vines to carry two young rods, one on each side, and these sprang from a point 6 feet from the soil, close to the lowest training wire. One of the young rods developed into the normal type, precisely similar to the parent rod; the other was much coarser in growth, did not ripen its wood well, and

carried leaves exactly like those of Canon Hall Muscat. When this rod fruited, the Grapes, too, were precisely similar to Canon Hall, being very large, round in berry, and the bunches set very badly indeed. Now and then we got a fairly good bunch, but the results generally were so bad that after a few years' trial I cut out the rod. During its existence it was seen in fruit by many who were perfectly familiar with both Grapes, and all were agreed as to the complete resemblance to Canon Hall. I made no attempt to propagate from the rod, as the absolute impossibility of getting a good set throughout made it worthless, and since destroying it there has been no recurrence of the freak on any portion of the Vine. *J. C. Tallack, Livermere Park Gardens, Bury St. Edmunds.*

GRAPES AT THE ROYAL AQUARIUM.—Mr. C. Bayer of Forest Hill, whose able gardener, Mr. Taylor, exhibited such a very fine collection of Grapes at the Drill Hall on October 26, comprising thirty-four bunches in thirteen varieties—a considerable feat for the time of year, again showed his cultural capacity in Grape-production at the Royal Aquarium on the 7th inst., when he set up eighteen capital bunches in five varieties, an admirable mid-winter exhibit, all the bunches being excellent. There were six Muscat of Alexandria, the finest being model bunches, long, tapering, and berries good and richly-coloured; three Lady Downe's, very long, compact, handsome, and black; four Gros Colman, two of the bunches being twins, yet very fine in berry, and well finished; three Black Alicante, intensely coloured; and two Trebbiano, bunches of good useful size, and berries clean and very bright. Such a Grape exhibit merits high commendation. *A. D.*

PLANT NOTES.

BEGONIA FUCHSIODES.

THIS charming Begonia, introduced to this country more than fifty years ago, still remains one of the best of winter-flowering varieties. Its culture is simple, and habit of growth graceful and free. Cuttings of the plant struck in the spring, and grown on in garden-frames, make plants of a useful size by the autumn, when, if introduced to an intermediate-house, they soon open their flowers, and in the month of December are at their best, continuing in bloom more or less throughout the winter. The plant also flourishes when planted out in a warm conservatory, and for draping pillars it is one of the best flowering subjects for the winter. At the present time some plants, 8 to 10 feet high, growing in a border in a warm-house in Mr. Astor's garden at Cliveden, Maidenhead, are nicely in bloom, and their pendent crimson-scarlet flowers are making them exceedingly attractive plants. *C. H.*

BROWN ROT IN TURNIPS AND CABBAGES.

DURING the past three or four years this disease has proved very destructive in various parts of the United States, and has been investigated by Dr. Erwin F. Smith. The symptoms are very marked; in Turnips the leaves are green and healthy, but the roots remain dwarfed, and resemble small Carrots rather than globose, or flat-bottomed Turnips. Although appearing healthy on the outside, on being cut across, the flesh of the root is seen to be brown, and eventually becomes more or less hollow, and remains fairly dry to the last.

In Cabbages the woody portion of the stem is dark brown; yellowish patches, with black veins, are also present on the leaves. The tissues remain dry, and there is no offensive smell. The characteristics of the disease are therefore a browning of the vascular portions of the plant, accompanied by dwarfing; Turnips fail to develop a root, and Cabbages are prevented from forming a head. Microscopic examination showed the brown vessels of the plant to be crowded with a minute organism called *Pseudomonas carpepestis*, and inoculations with pure cultures of this organism have proved that it is the cause of the disease.

When once present, the disease often spreads

rapidly, and experiments have shown that the inoculation of healthy plants can be effected by slugs, which have previously fed on diseased plants. The larvae of the Cabbage-butterfly also carry the disease in a similar manner. A second mode of infection, independent of the aid of animals, and without the presence of a broken surface of the leaf, occurs when the *Pseudomonas* happens to come in contact with the minute drops of water exuding, during the night, from the water-pores situated on the margin of the leaf. These pores are large enough to allow the organism to pass into the interior of the leaf. Rape and Radish are also susceptible to the disease. The preventive methods suggested, are (1) The cultivation of Crucifers on land not infected with the disease; (2) Prompt removal and destruction of diseased plants; (3) A constant war upon insect enemies and other possible carriers of the disease. *G. M.*

VEGETABLES.

NEW POTATOS.

IN order to obtain "new" Potatoes during the last three months of the year all that is required are some garden frames or brick-pits, and a sufficient number of sets selected in the spring to fill them, placing the sets in an upright position in shallow boxes, and storing them, till planted, in the coolest place possible, which at Rolleston is the passage leading to the Ice Well, where they do not push out growths to any appreciable extent. Towards the end of June the boxes of sets are placed in the Potato-shed, and gradually accustomed to the light; they are then planted in frames, &c. in the usual manner—making one planting early in July, and another 14 days later. The soil is sometimes very dry, and it must be sufficiently moistened by being afforded frequent applications of water a week or more previously to planting the sets. No protection is of course required till early autumn frosts are feared, when sufficient covering should be employed to protect them from injury. In the daytime, when the weather has got cool, or heavy rain is apprehended, the lights should be made use of; and at other times the plants should be fully exposed. The sets should be planted rather thickly in the rows, and the latter about 15 inches apart. Planted in this manner, and at the dates given, good crops of medium-sized tubers will be produced that are fit for the table during the last three months of the year. Three trustworthy varieties to plant are Veitch's Improved Ashleaf, Sutton's Ringleader, and Sharpe's Victor. *G. Woodgate, Rolleston Hall Gardens, Burton-on-Trent.*

Obituary.

D. E. H. BOXMANN, a prominent Dutch amateur, died at Oudwijk, his residence, near Utrecht, on November 18, in his fifty-eighth year. The deceased was possessed of a considerable Orchid collection.

JOHANN N. HAUSER, the oldest florist of New York, died on October 24, in his eighty-first year. He was a native of Bavaria, and practised as a youth chiefly in Leipzig, Vienna, and Paris. He enjoyed as a young man of twenty-five years a good reputation as a landscape-gardener, and as such he was placed in charge of one of the royal gardens in Paris, which appointment he retained till 1844. He then emigrated to New York, and in company with a Parisian friend established a plant-nursery, of which, owing to the death of his partner, five years later, he became sole owner. Hauser's specialty was Camellias; and notwithstanding the introduction of improved varieties of Roses and Chrysanthemums, and of Orchids, the Camellia remained his favourite flower to the last. *Möller's Deutsche Gärtner Zeitung.*

DAVID MCEWEN—East Anglian readers of the *Gardeners' Chronicle* will learn with feelings of regret of the decease of Mr. David McEwen, who for the past twenty-nine years carried on a business as

seedsman and florist in Red Lion Street, Norwich. He started his business career with the late firm of Mackie & Ewing, seedsmen, of Exchange Street, and later on, taking over the management, he stayed with that firm for upwards of twenty-two years, gaining the respect of both employer and employed, whilst his qualifications as a business man were shown by the firm's numerous customers. On Mr. McEwen leaving this firm he was the recipient of a handsome testimonial in acknowledgment of the long and honoured services he had rendered. The deceased, who was in his seventy-ninth year when he died, was known far and near as an authority on horticultural seeds.

SOCIETIES.

ROYAL HORTICULTURAL.

DECEMBER 14.—On Tuesday last, in the Drill Hall, James Street, Westminster, took place the last meeting for the year of the Committees of the Royal Horticultural Society. Though the day proved to be a more agreeable one than was expected, the weather immediately prior to Tuesday was so adverse, that a larger exhibition than was witnessed could hardly have been anticipated. Chrysanthemums, though less imposing than of late, still lingered to vie with the bright zonal Pelargoniums, the Primulas, Euphorbias, Calanthes, Cyclamens, Carnations, Cyripediums, and other Orchids, and the magnificent Socotrana hybrid Begonias. The work before the Floral Committee proved to be very little, occupying but a few minutes, and one Award of Merit and no First-class Certificate was granted. Before the Fruit Committee there were staged several collections of Apples, a good number of Tomatoes, and a few vegetables.

Professor HENSLOW delivered a lecture upon "Sports in Chrysanthemums," alluded to in another column.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. H. B. May, Chas. E. Pearson, Rich. Dean, J. H. Fitt, Geo. Stevens, Jno. Hudson, J. F. McLeod, Thos. Peed, J. Jennings, C. J. Salter, Chas. Jeffries, W. Bain, Geo. Gordon, Chas. E. Shea, H. J. Jones, H. J. Cutbush, Ed. Beckett, R. M. Hogg, Jas. Walker, Ed. Mawley, G. H. Engleheart, Geo. Paul, Chas. Blick, and H. Turner.

A pretty group of plants of the winter-flowering Begonia Gloire de Socaux, interspersed with a few Dracenas and other foliage plants, was staged by Mr. W. Farr, gr. to A. PEARNS, Esq., Spring Grove, Isleworth. This Begonia has attractions beyond its very pretty flowers, in the dark metallic-like, but handsome, foliage it possesses. From the same garden was exhibited a large group of Euphorbia (Poinsettia) pulcherrima plants, carrying developed bracts (Silver Banksian Medal).

A white flowering Carnation, probably a selection from the C. Marguerite named Miss Lilian Hillier, was shown by Messrs. E. HILLIER & SONS, 95, High Street, Winchester.

Mr. JAS. BRYSON, nurseryman, Helenburgh, showed several varieties of single-flowered Chrysanthemums, but none of these was of exceptional character.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Foad, Chelsea, displayed varieties of their new type of Begonias, crosses between the tuberous section and the species B. Socotrana. An Award of Merit was recommended on this occasion to Winter Cheer, from B. Socotrana ♀, and a tuberous variety ♀. The flowers are produced in abundance in large trusses, and are warm rosy-carmine in colour. The growth is erect, and the leaves green. Its valuable character is attested by the wealth of colour produced at such a season. The Ensign, a semi-double variety, previously exhibited here and certificated, was also shown.

Messrs. HUGH LOW & CO., Clapton, and Bush Hill Park Nurseries, Enfield, exhibited a group of Cyclamens, and some pretty plants of Winter Scarlet Carnation. This winter-flowering variety is very fine in colour, and has a non-bursting calyx (Bronze Banksian Medal).

Mr. H. J. JONES, Ryecroft Nursery, Hither Green, Lewisham, made, we may conclude, his last display of Chrysanthemums for the season. Exhibited in his usual manner, some of the blooms were quite fresh and good in colour; others, however, had evidently already been open for some time (Silver Floral Medal).

A group of Chrysanthemum-plants was staged by J. W. TEMPLE, Esq., Leyeswood, Tunbridge Wells (gr., Mr. F. Cubberley). It was composed of the variety Princess Blanche, a white or very pale rose-coloured decorative bloom, and a yellow sport from same known as Janet Shehan. They were capitally grown bush-plants, dwarf, with nine or a dozen stems upon each, and one bloom upon a stem. The foliage was healthy-looking to a degree; the blooms, however, had been brighter and fresher than when staged (Silver Floral Medal).

Double-flowered Primulas were shown by Messrs. W. COTBUSH & SON, Highgate, London, N. This group of plants, mostly in 6-inch pots, included the varieties Princess,

double white or faintly tinted, and Marchioness of Exeter, double rose (Silver Banksian Medal).

Messrs. H. CANNELL & SONS, Swanley, Kent, put up a few sprays of their choicest zonal Pelargoniums, and relieved the same very tastefully with Adiantum Ferns. The only pure white one was Niagara; then follow white and pink or white and rose, in Mrs. Simpson (a novelty), Duchess of Marlborough, and Lady Tennyson. Shaded varieties are Dryden, Madame Hoste, and Countess de Morella. Fine scarlets were noticed in Lord Farrer, Harriack, and Soldier's Tunic; crimsons, in Nicholas II. (a novelty), King of Crimsons, and Shelley; purples, in Lord Reay (a novelty) and Royal Purple. The variety Owen Thomas, a very bright scarlet flower with pure white eye, is very deserving of mention (Silver Banksian Medal).

That pretty stove-trailer, Cissus discolor, occasionally flowers when making long vigorous growths, but not frequently. It was shown blooming profusely by W. C. WALKER, Esq., Percy Lodge, Winchmore Hill (gr., Mr. Geo. Cragg). The flowers are not very conspicuous, but they add to the attraction and interest of the plant to some extent.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. J. O'Brien (Hon. Sec.), De B. Crawshaw, H. M. Pollett, H. Ballantine, W. H. White, H. J. Chayman, W. H. Young, F. J. Thorne, E. Hill, J. Douglas, T. W. Bond, T. Statler, C. Winn, S. Courtauld, and T. B. Haywood.

The last meeting of the year was graced by a large display of winter-flowering Orchids. Sir TREVOR LAWRENCE, Bart. (gr., Mr. W. H. White), staged an effective group, in which groups of the newer hybrid Calanthes formed the chief feature. Among them the most brilliant rosy-crimson variety was Calanthe × Burfordensis (Award of Merit); and scarcely less effective was the showy C. × Veitchi splendens (Award of Merit). C. × varicolor, white, with an eye of a delicate peach blossom shade of pink; C. × Bryan, white, with dark purple eye; C. × amabilis, pale rose; C. × Veitchi lactea, a pale white; C. × Wylamiana, a charming variety; C. × porphyrea and C. × sanguinaria, a dark crimson variety, which also secured an Award of Merit. Among the other exhibits in this group that were remarkable, mention may be made of "Brasso-Catt-Lelia × Lindleyana elegans" (Brasso-Catt-Lelia × Lindleyana × Lellio-Catt-Lelia × elegans), a hybrid that affords an idea of the complication in form of flower and leaf, &c., likely soon to arise. It bore an inflorescence of pretty flowers with bluish-white sepals and petals, and dark purple labellum (Award of Merit); Masdevallia corniculata, with numerous inflated yellow and red flowers (Botanical Certificate); M. irrorata; a fine specimen of Platyclinia uncatia; a grand example of Bulbophyllum Medusa, with ten large heads of flowers (Botanical Certificate and Cultural Commendation); Dendrobium cymbidifolios, with numerous sprays of singular-looking white flowers (Cultural Commendation); Cyripedium × Leeanum giganteum, C. × Laurebel, C. × concolor-bellum, and C. × callo-bellum; the rare Milionia Endresii, a fine variety of the remarkable M. Russelliana; Masdevallia Schroderiana, &c. The group was awarded a Silver-gilt Flora Medal.

Messrs. JAS. VEITCH & SONS, Ltd., Royal Exotic Nursery, King's Road, Chelsea, were awarded a Silver Flora Medal for an attractive group, consisting principally of new or rare hybrid Orchids. Of these shown for the first time were Lellio-Catt-Lelia × Loucusta (C. bicolor ♀, L. harpophylla ♂), a charming novelty with sepals and petals of a clear yellow tint; the lip having the cream-white side lobes folded over the rather thick column, and the narrow elongated purple front lobe peculiar to C. bicolor hybrids; Cyripedium × Minosa magnificum (Spicerianum ♀, Arthurianum ♂), with very handsome white and purple upper sepal; and C. × Aeson giganteum (insigne ♀, Druryid ♂), a noble flower of great substance, and fairly intermediate between the species used in producing it, the prevailing colours being yellow and reddish-brown (Award of Merit). Also in the group were some good plants of Cattleya × Mantini; three varieties of the pretty C. × leucoglossa, the handsome Lellio-Catt-Lelia × Eunomia, and three fine forms of L-C. × Pallas, Cyripedium × Euryades, C. × Niobe, C. × Enone, C. × Sedem candidulum, and other varieties.

Messrs. HUGH LOW & CO., Clapton, secured a Silver Banksian Medal for a showy group comprising the handsome Cyripedium × Leeanum, Low's variety, a fine rival of C. × L. giganteum; C. × Minos magnificum, the apricot-tinted Lycaste Skinneri armenica, Cyripedium insigne Laura Kimball, C. × Sallieri Hyeaunum, C. × Pitcherianum, Williams' var.; C. × Bellona, C. × Dauthierii, Cymbidium × Winnianum, Dendrobium × Cassiope and D. × Leochlanum, Lelia anceps, Cattleya Percivaliana, Oncidium anthocrene, Cynorchis Lowi, Angreum sesquipedale, &c.

Messrs. F. SANDER & CO., St. Albans, staged a group of good hybrid Calanthes, &c., noteworthy being Calanthe × Bryan, C. × Florence, C. × Victoria Regina, and C. × Bella, all very handsome and effective varieties; Phalo-Calanthe × Arnoldii superba, a very pretty flower, with greenish-white sepals and petals, tinged with pink, and lip closely marked with rose-purple, formed part of the group.

Messrs. B. S. WILLIAMS & SONS, Victoria and Paradise Nurseries, Upper Holloway, staged good examples of Odontoglossum polyanthum, Oncidium tigrinum and O. varicosum, Calanthe × bella, C. × Veitchi alba and C. × Oweniana; the last-named having flowers of a peculiar tint of carmine-rose, with some cream-coloured markings; Cyripedium × calophyllum, C. × Harrisianum var., C. insigne albo-marginatum, C. i. Maulei, C. i. Mrs. Wils n, C. i. punctatum

violaceum, C. × Leeanum superbum, C. × nitens superbum, C. × Sallieri, Zygotopetulum Mackayi, &c.

Sir FREDERICK WIGAN, Clare Lawn, East Sheen, Richmond (gr., Mr. W. H. Young), showed the fine Trichoplia brevis illustrated in the *Gardeners' Chronicle*, Nov. 30, 1895, p. 641 (Award of Merit); the clear white Maxillaria grandiflora alba, and the large and distinctly marked C. insigne Wigan's variety, characterised by the very large spots in its broad upper sepal.

Admiral Sir HENRY FAIRFAX, Ravenswood, Melrose, sent a fine variety of Lelia anceps, which might be called an improvement on L. a. Amesians.

DE B. CRAWSHAW, Esq., Rosefield, Sevenoaks (gr., Mr. S. Cooke), showed Lelia anceps, Mrs. de B. Crawshaw, a very large and handsome form, especially remarkable in the dark purplish rose colouring of the sepals and petals (Award of Merit).

C. J. LUCAS, Esq., Warnham Court, Horsham (gr., Mr. Duncan), showed the fine Lelia anceps Schrodern; and Baron SCHRODER, The Dell, Staines (gr., Mr. Ballantine), showed Lelia anceps Chamberlainiana, still the largest and best of its class.

Mr. JAS. DOUGLAS, Edenside, Great Bookham, sent Lelia × Briseis (harpophylla × purpurata), a very curious and pretty hybrid, with sepals and petals of white, tinged with lemon-yellow, and a narrow white lip bearing slight rose-colour marking on the front lobe—a singular and pretty hybrid (Award of Merit).

W. THOMPSON, Esq., Walton Grange, Stone, Staffordshire (gr., Mr. W. Stevens), showed Cattleya × Miranda (Trianae ♀, guttata Prinzl ♂), with rosy lilac sepals and petals, slightly spotted with purple; the front lobe and tips of the side lobes of the lip being rich claret-purple colour. R. W. RICKARDS, Esq., The Priory, Usk, showed Lelia purula superba, the largest and best form of the species shown this year (Award of Merit). H. DAUCE, Esq., The B-ches, Circus Road, St. John's Wood (gr., Mr. Walker), sent a singular form of Oncidium varicosum, with abbreviated labellum, the base and sides of which were coloured red-brown. MALCOLM S. COOKE, Esq., Kingston Hill (gr., Mr. W. Buckall), showed two good varieties of Oncidium Forbesii. J. T. BENNETT-POE, Esq., Holmewood, Cheshunt (gr., Mr. Downes), sent the fine white Calanthe × Harrisii, which was accorded a First-class Certificate.

THOS. McMEKIN, Esq., Falkland Park, Norwood (gr., Mr. A. Wright), showed Cyripedium × Mrs. Geo. Bollerill (Lathamianum × Savageanum superbum); and C. insigne, Falkland Park variety, both fine flowers.

Mr. T. DUCK, Abbey Wood, Kent, showed Cyperorchis Mastersii album, with entirely white flowers.

WALTER C. WALKER, Esq., Percy Lodge, Winchmore Hill (gr., Mr. Geo. Cragg), showed Lelia rubescens (Award of Merit); a very fine variety of L. albidia, and an inflorescence of Odontoglossum cirrosum with foliaceous bracts.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, showed ten basketsful of Cyripediums in good health, grown in a house where the temperature often falls to 40° Fahr. The foliage was very short and thick, and flowers good. They were C. Spicerianum, C. × Ashburtoniae, C. × Harrisianum, C. insigne Wallacei, C. i. grandiflorum, C. i. albo-marginatum, C. i. Sylhetense, and C. i. Chantini (Vote of Thanks).

WALTER CUBB, Esq., Dulcote, Tunbridge Wells (gr., Mr. Howes), showed a fine plant of Cyripedium × J. Howes (Sallieri Hyeaunum × villosum aureum), a grand improvement on the best form of C. × Sallieri.

F. W. MOORE, Esq., Royal Botanic Gardens, Glasnevin, Dublin, sent Oncidium saltabundum (Botanical Certificate), Maxillaria mirabilis, M. punctata, and a pretty unspotted variety of the same; a fine large form of Cyripedium insigne, and a yellow C. insigne near to C. i. Ballie, but larger; and Vanda lamellata Boxallii.

Fruit Committee.

Present: Philip Crowley, Esq., Chairman; and Messrs. W. Pope, J. Wright, A. F. Barron, Jas. H. Veitch, Jos. Chal, Geo. Bunyard, Alex. Dean, J. W. Bates, W. Farr, Geo. Woodward, W. J. Empson, Jno. A. Laing, Geo. Wythes, H. Balderson, Robt. Fife, F. Q. Lane, Geo. Reynolds, and J. Willard.

Sir TREVOR LAWRENCE, Bart., Burford Lodge, Dorking (Mr. Bain, gr.), showed fine roots of Celeriac Geant de Prague, (Award of Merit); Celeriac a feuille panachee, and two heads of the delicious Couve Tronchuda or Braganza Cabbage (Cultural Commendation).

Mr. A. OUTRAM, 7, Moore Park Road, Fulham, S.W., showed Celery Jubilee Red, a variety resembling Major Clarke's, but with finely-cut leaves.

Miss BASTON, Sandhurst, Berks (Mr. R. Handley, gr.), showed three Cardoon-stems, and some small-sized Yams, looking like Dioscorea batatas.

A dwarfish Celery, named Sutton's Solid White, was shown by Mr. WRIGHT, of the Royal Horticultural Society's Gardens, Chiswick. It was particularly tender, and pleasant eating (Award of Merit).

Mr. J. CROSS, Bury St. Edmunds, showed a Celery called Victoria Pink, a strong-growing variety.

Mr. S. MORTIMER, nurseryman, Rowledge, Farnham, had a fine exhibit in a dozen boxes of fine-looking Tomatoes—Selected, Conqueror—of a glistening crimson colour, obtaining a Silver Banksian Medal for the exhibit.

Mr. O. THOMAS, gr. to the QUEEN, Frogmore, showed a new variety of Cucumber, All-the-Year-Round, which has been previously noticed in these columns. The six fruits shown were capitally developed for the season, and had the bloom still remaining on each.

Mr. H. BEARWICK, Sidmouth Nurseries, Sidmouth, showed a collection of Apples, numbering fifty-six dishes and varieties, receiving a Silver Knightian Medal in recognition of their merit. The collection contained many of our best dessert and culinary varieties, as well as some others seldom seen about London, as Reineette d'Osabruck, Roundway Magnum Bonum, Winter Majestic, and Tom Putt.

A small collection of Apples came from the Earl of GALLOWAY's garden, Galloway House, Gariestown, N.B. (gr. Mr. J. Day). They were very good produce for a garden so far north, and included Warner's King, Peasegood's Nonsuch, Wellington, Tower of Glamis, Galloway Pippin, Bramley Seedling, and Loddington, these being the largest fruits. Blenheim Orange, Ribston, Fearn's and Cox's Orange Pippins, and Golden Noble were much below the size obtained in the South, but in other respects they were good examples. Some good specimens of Allia Craig Onion, from seed sown on February 25, and transplanted to the open ground April 28, came from this exhibitor (Silver Banksian Medal).

PEAR AND APPLE COMPETITION FOR FLAVOUR.

Pears.—1st (Award of Merit), to the variety President Barabe, a medium-sized, obovate fruit, with a russet yellow rind, shown by Mr. Allan, gr. to Lord SUFFIELD, Gunton Park, Norwich; 2nd, Winter Nellis, shown by Mr. G. Wythes, gr. to Earl PERCY, Syon House, Brentford.

Apples.—1st, Adams' Pearmain, shown by Mr. C. Herrin, gr. to the Hon. G. M. FORTESCUE, Drogheda, Maidenhead; 2nd, Cockle Pippin, shown by Mr. C. Ross, gr. to Col. A. HOUNSLOW, Welford Park, Newbury.

The number of dishes shown in these competitions was about twelve of Pears, and twenty of Apples.

NATIONAL ROSE.

Annual Meeting.—Dec. 9.

REPORT OF THE COMMITTEE FOR THE YEAR 1897.

THE great event of the past year, the celebration of Her Majesty's Diamond Jubilee, has, in one way or another, affected most of the institutions in this country—some beneficially, others the reverse. The National Rose Society has not escaped its influence. It materially affected our southern exhibition at Portsmouth, even to the altering of the date, which was originally fixed for the day after the Jubilee celebration. As it was felt impossible to hold the show under such circumstances, the fixture, at the request of the local committee, was changed to June 18. This is the earliest date on which a provincial show has ever been held by the Society. The exhibition proved an unusually small one, while the attendance of visitors, no doubt in some measure owing to the stormy weather during the afternoon, was also very limited. The fine display of garden Roses was a noteworthy feature of this exhibition. Everything that could be done under the depressing circumstances of the day was carried out by Captain Ramsay, our local secretary, who not only gave his valuable services, but also a Silver Cup in the leading class for amateurs. The committee are also greatly indebted to the kind hospitality of Mr. Alderman Evans, who kindly entertained the judges and principal exhibitors to a luncheon in the Town Hall.

The metropolitan show at the Crystal Palace was also affected, but not in the same way, by the Jubilee celebration, for the Palace Victorian exhibition occupied the whole of the nave. Consequently, that of the National Rose Society had to be relegated to the central transept and the concert room, the latter a most unsuitable position for a Rose show, particularly on such a dull day as that on which the exhibition this year took place. It was the largest show that the Society has yet held, no fewer than 7200 blooms having been staged on that occasion in addition to the many beautiful stands of garden-Roses.

The northern show, which was held at Norwich, in the grounds of Mr. J. J. Colman of Carrow Priory, was a most successful one, and attracted a larger number of visitors than any previous summer exhibition of the local Society. The arrangements were, on the whole, excellent, and reflected great credit on the committee of the Norfolk and Norwich Horticultural Society, and especially upon their energetic secretary, Mr. J. E. T. Pollard.

Early in the year application was made to the different railway companies for a reduction in the rates charged for the carriage of Rose-boxes, with the result that, although no reduction was granted, there is now a uniform rate charged on nearly all lines throughout the country, which previously was far from being the case.

It is with much regret the committee have to record the deaths of two of their oldest members—Dr. Robert Hogg, a Vice-President of the Society, and one of its original founders, who for many years took a warm interest in its welfare, and frequently presided at the meetings; and the Rev. E. N. Puchin, who in the early days of the Society was not only a member of the committee and a constant exhibitor, but also a leading authority on all matters connected with the Rose.

FINANCE.—The financial position of the Society must be regarded as satisfactory, considering how greatly most societies of the kind have suffered this year through the many demands upon their members' pockets owing to the celebration of Her Majesty's Diamond Jubilee. The year was begun with a balance in hand of £76 12s. 3d.; and now, after paying all outstanding expenses, including £495 in

prize-money, there remain £30 18s. 7d. in the Treasurer's hands.

The sale of publications realised £8, which is more than in any previous year.

ARRANGEMENTS FOR 1898.—Various suggestions have been made with a view to increase the efficiency of the Society, and these are now engaging the attention of the Committee. The engagement for the coming year are likely to prove unusually satisfactory, as the provincial exhibitions will be held in places which the society has already visited, and where large Rose shows are each year being held. The southern exhibition will take place at Bath, in conjunction with the Bath Floral Fête and Band Committee, on Thursday, June 23. The metropolitan show at the Crystal Palace on Saturday, July 2, when, we are informed, there is every prospect of the nave being once more placed at the disposal of the society. The northern exhibition will be held at Halifax, under the auspices of the Salterhebble and District Rose Society, on Thursday, July 14.

A Rose Conference will take place at each of the provincial exhibitions, when some subject of interest in connection with Rose culture will be discussed. A report of the Conferences will be afterwards published, and issued to the members later in the year.

MEMBERS' PRIVILEGES.—Members subscribing £1 will, as usual, be entitled to two private view and four transferable tickets, the latter admitting at the same time as the general public; while subscribers of 10s. are entitled to one private view and two transferable tickets. Each of these tickets is available for any one of the society's exhibitions. Members joining the society for the first time in 1898 will also receive copies of the following publications: The official catalogue, the supplement to the catalogue, "Hints on planting Roses," and the "Prize Essay on the Hybridisation of Roses," also the reports of the two conferences as soon as issued. Members alone are entitled to compete at the society's exhibitions.

The committee, in conclusion, express their best thanks to their local secretaries, also to the donors of special prizes. Of the former Mr. H. P. Landon has distinguished himself by obtaining more new members for the society during the last three years than any of his fellow secretaries. Among the leading donors of special prizes may be mentioned the Right Hon. Lord Pensance, the Mayor of Norwich, Dr. S. P. Budd, Mr. C. J. Grahame, Captain Ramsay, Mr. C. E. Shea, Mr. A. Tate, and the Trustees of the Prince Memorial Fund.

SCOTTISH HORTICULTURAL ASSOCIATION.

DECEMBER 7.—This society met on the above date at St. Andrew Square, Edinburgh, to hear the last paper of the session of 1897, entitled "Exotic Ferns, their Propagation and Culture," by Mr. R. B. WRIGHT, Wariston Nurseries, Edinburgh. The paper, which was a comprehensive one, treated the subject in an exhaustive manner, beginning with a description of the order Filices, and giving an account of their habitats. After giving a few hints upon the best modes of propagation and cultivation, Mr. Wright gave an alphabetical list of the genera, pointing out their characteristics, and at the same time referring to anything specially necessary for their successful culture. At the close of the paper, several of the many members present took part in the discussion, and the reader of the paper was given a cordial vote of thanks for his instructive essay.

Among the exhibits were some fine Chrysanthemum blooms of a golden sport, especially suitable for cutting purposes, shown by Mr. A. PORTER, Davidson Mains, Midlothian. A splendid bloom of Mrs. C. BLICK was also upon the table from Mr. MURRAY, vice-president of the association.

As showing the rapid growth of membership in this society, it may be mentioned that thirty-five new members were proposed and seconded for election. At the close of the meeting, the Treasurer, Mr. ALEX. MACKENZIE, stated that the financial aspect of the last Chrysanthemum show was most satisfactory; and the President, Mr. TODD, read out a list of institutions to be benefited by the surplus proceeds. This sum was allocated as follows by the Council:—£100 to the Royal Infirmary, Edinburgh; £50 to Sick Children's Hospital, Edinburgh; £50 to Royal Ga'deners' Orphan Fund; and £50 to the Royal Gardeners' Benevolent Institution.

Before the meeting broke up, a telegram was received and read to the members by the President from the National Chrysanthemum Society, congratulating them upon the success of the last show, the Secretary, Mr. R. Laird, having gone to London to represent the Scottish Horticultural Association.

NATIONAL CHRYSANTHEMUM.

DECEMBER 7.—Though a good number of subjects was staged on this occasion, only one Certificate of Merit was awarded, viz., to incurred Miss Phyllis Fowler, a large full flower with good smooth petals of a pale soft yellow tint. This variety came from two or three exhibitors, and it being a rule with the society that the one showing the best should have the Certificate awarded to him, who, in this case, was Mr. T. ROBINSON, gr., Elsfield House, Hollingbourne. It was also shown in good character by Mr. H. J. Jones.

Incurred Egyptian, a deep bronzy-coloured variety, was shown by two or three exhibitors, but the flowers were too coarse at the base to find favour, though it appeared to be a useful late-flowering variety.

Japanese Mrs. M. Simpson, a large white variety, with moderately broad florets, somewhat loose as shown, was Commended.

A semi double, bright, orange-chestnut coloured variety named Duchess Elizabeth, with a slightly bronzy reverse, from Mr. A. F. IGATE, Burhill, Walton-on-Thames, was commended as a market variety on account of its remarkable freedom of flowering in large sprays. A white Anemone-flowered variety named Mrs. Carteret, shown by Mr. H. J. Jones, is also a remarkably free bloomer, but the flowers are somewhat loose.

The variety certificated at the previous meeting under the name of violaceum in perfect good faith by Mr. E. Beckett, under the impression that it was an unnamed seedling, is variety raised by Mr. H. J. Jones, and sent out under the name of Dennis Smith-Rylands, and the name violaceum is therefore expunged.

DEVON AND EXETER GARDENERS'.

DECEMBER 8.—Mr. G. Camp, gr. to Mr. E. BYRON, of Culver, near Exeter, read a paper on "Winter-flowering and Ornamental Begonias," at the meeting of this body on the date given. The lecturer sketched the history of the Begonia from the introduction of *B. nitida* from Jamaica to Kew in 1777, summarising the development of the genus as indoor decorative plants, and giving the characteristics of the leading species and varieties. He mentioned the four methods of reproduction—seed, cuttings, leaves, and bulbils, remarking that raising from seed, where proper appliances were at hand, was easy enough, but it required close attention. Propagation of the leaf was not difficult: the operation consisted of cutting a leaf into small pieces, and inserting each piece sideways in well-drained pots, filled with finely-sifted loam, leaf-mould, and cocoanut fibre refuse, in equal proportions, with a thin covering of silver-sand. Cuttings succeeded in the same kind of compost. He did not recommend bulbils as a means of propagation. When propagation from the leaf was adopted, care should be taken to use well ripened leaves. The early spring was the best time in which to strike the Begonia from cuttings, these consisting of ripened shoots. When rooted they should be plunged in a bed having a bottom-heat of 78° to 82°, shaded from the sun, and kept in a close, moderately moist condition. When established more air is necessary.

Among the many varieties now grown, he recommended those which had been obtained from *B. Socotrana* as being among the most satisfactory. While not in the least disparaging the acknowledged beauty and usefulness of the tuberous-rooted sorts, he regretted that so little attention was bestowed on the fibrous-rooted, the ornamental-foliated, and the fragrant-flowered Begonias, many of these being winter-bloomers, and possessed of gracefulness which made them of much value as decorative objects. Then, again, the broad, hirsute, bronzy, elephant-eared foliage of others made an excellent contrast to *Adiantums*, *Grevilleas*, *Ococos*, and other light subjects in general use in conservatories and warm greenhouses.

NATIONAL DAHLIA.

DECEMBER 14.—The annual meeting of members took place at the Hotel Windsor on the above date, Mr. T. W. GIBBS-STON, the President, in the chair, growers and exhibitors from all parts of the country being present. The tone of the meeting was decidedly buoyant, and there are indications that the Society has passed through one of the most successful seasons of recent years.

The annual report, read by Mr. J. F. HUDSON, the Secretary, dwelt upon the fact that the lack of rain at the beginning of the year made close attention to watering necessary; but later, when moister weather-conditions prevailed, the plants made rapid progress, and in some cases exhibition blooms were produced much earlier than usual. The annual show in September was more extensive than formerly; about 300 entries were made, and the general quality of the flowers was very high, notably in the Cactus section. A special commemorative class was included in the schedule, intended to illustrate the increased development of the Dahlia during the reign of the Queen; and some tasteful decorative effects resulted. New classes for blooms in vases, to show how the Dahlia could be employed for house decoration, were included, and brought several competitors, the feature proving a successful innovation. Some classes were added for those who had not previously won a prize at an exhibition of the society; and these were the means of bringing together creditable exhibits from new members, and they will become a permanent feature in the schedule.

The exhibits of Cactus varieties were numerous, there being a marked increase among the amateurs; the number of new varieties produced was very large, and several Certificates of Merit were awarded. Some novel varieties have put in appearance, most prominent being *Arachne*, a striped variety, and the first bi-coloured form of good Cactus character. The report concluded by stating that the time had arrived when it would be necessary to exercise the greatest care in awarding Certificates of Merit to new Cactus varieties; and to the loss sustained by the death of Dr. Hogg, one of the Vice-Presidents. It was reported that the large number of 2300 blooms were staged at the last exhibition.

The financial statement, read by the Treasurer, Mr. E. Mawley, showed that the income of the Society from all sources had amounted to £173 18s. 6d., in addition to the balance in hand at the commencement of the year, that the working expenses had amounted to £21 8s. 9d., prizes £139 19s., leaving a balance of £21 1s. 1d. to be carried forward.

The Duchess of Sutherland, the Countess of Pembroke, the Countess Sherbrooke, and other ladies were added to the list of patrons. Mr. T. W. Girdlestone was re-elected president, and the Dean of Rochester, Sir Edwin Saunders, and Mr. Thomas Pendered, president of the Wellingborough Dahlia Society, were made vice-presidents. Mr. E. Mawley was elected treasurer; Mr. J. F. Hudson, secretary; and Messrs. F. W. Fellowes, C. E. Wilkins, H. A. Needs, and Dr. Bartrum, were added to the committee. The schedule of prizes was revised, some classes were struck out, and others added, including one for twelve Fancies in the open division; the list of true Cactus varieties also underwent revision, the certificated flowers of the present year being added. The meeting closed with a hearty vote of thanks to the officers, and to the president for presiding.

The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.W.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Graining, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending December 11, is furnished from the Meteorological Office:—

"The weather during this period was extremely changeable, with frequent heavy rain in nearly all parts of the Kingdom. Considerable falls of sleet and snow were experienced in the north about the middle of the week. Brief intervals of fine bright weather prevailed occasionally, but these occurred mainly at night.

"The temperature was very unstable, but on the whole rather above the mean in all districts excepting Ireland, N. The highest of the maxima were registered on the 7th, and ranged from 58° in Ireland, S., and 56° in England, N.W., to 51° in Scotland, N. The lowest of the minima which were recorded, as a rule on the 6th, varied from 25° in Scotland, E. to 33° in Scotland, W., and to 39° in the Channel Islands.

"The rainfall exceeded the mean in all districts. In most of the western and northern districts the fall was more than twice as much as the mean. The heaviest aggregate falls recorded during the week were 3.85 inches at Arlington, 3.65 inches at Stornoway, and 3.64 inches at Fort William.

"The bright sunshine was less than the mean in most of the northern and north-western districts, but exceeded it in the extreme south and south-west. The percentage of the possible duration ranged from 30 in Ireland, S., and 28 in the Channel Islands, to 11 in Scotland, W., and England, N.W., and to only 2 in Scotland, N."

MARKETS.

COVENT GARDEN, DECEMBER 16.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

POTATOES.

Second class Potatoes have advanced a shade since last report. Present current prices—Up-to-date, 95s. to 115s.; Maincrop, 85s. to 110s.; Saxons and Bruce, 80s. to 100s.; Dunbar Maincrop, 180s.; Blackland, 72s. 6d. to 80s. per ten; Belgian and Dutch Ware, 3s. to 3s. 6d.; German Ware, 3s. 6d. to 5s. per bag of 50 kilos. John Bath, 82 and 84, Wellington Street, Covent Garden, W.C.

(Remainder of Markets carried forward to p. x.)

NOTICES TO CORRESPONDENTS.

A CANCELLED ENGAGEMENT: F. G. Smith. If you have lost money in a variety of ways, especially in travelling to and fro, you might succeed in obtaining redress in the County Court if you employed a solicitor. Is it worth the cost? You had better consult one before taking legal action.

BOOKS: H. W. C. O. L. The edition will be issued shortly in numbers probably, and in one volume. The old edition can be obtained at the publishing offices of Blackie & Son, London, Glasgow, and Edinburgh.

CANKER ON FRUIT TREES: T. G. The history is this:—The trees are injured by frost, or insect puncture, or other injury, leaving an open wound, in which the fungus spores settle, and germinate; the young plant feeds on the bark, and ultimately causes its death. A heavy undrained soil might naturally favour fungus growth, and cause weakness in the trees, but the fungus is the real cause of the mischief.

CARNATION: H. S. The disease is the red rust, Heterosporium echinulatum. The fungus on the weed is quite different, but we do not know what it is. If you want to know more, send us a better specimen.

CARNATION DISEASED: J. F. See answer to T. B. in our issue for the 11th inst.

CARNATIONS DISEASED: F. R. H. S. The fungus is Septoria Dianthi. Remove diseased leaves, and avoid overhead spraying, keeping the foliage as dry as possible. G. M.

CORDYLINE-LEAF. S. H., Newport. The pest is the ordinary small brown-scale, and from large, smooth leaves such as these, it may be easily removed by sponging with an insecticide, or with the mixture of soft-soap and paraffin, using a small wineglassful of paraffin to a gallon of soapy water, and keeping the mixture well-stirred.

DICKSONIA FRONDS: R. L. The effect probably of dryness of the soil and stem.

ERRATUM.—We are informed by Mr. W. Howe, of Park Hill Gardens, Streatham Common, that he, and not Mr. Gibson, as stated in our report last week, was awarded 1st prize for a collection of flowering, foliage, and berried plants, at the National Chrysanthemum Society's Show.

FUNGUS: W. G. Without knowing more particulars, we cannot give you any information. Send specimens.

NAMES OF FRUITS: W. Prunett. 1 and 4, not known; 2, Blenheim Orange; 5, Warner's King; 6, Maltater.—W. D. Pears. 1, Josephine de Malines; 2, Nouvelle Fulvie; 3, Bergamot d'Esperen; 4, Lamb Abbey Pearmain; 5, Beauchampwell.—W. Thomson. Wyken Pippin.—J. S., Sevenoaks. Apple Rosemary Russet.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—W. S. 1, Phaius grandifolius; 2, Maranta bicolor; 3, Arundo donax variegata; 4, Tradescantia discolor; 5, Eranthemum pulchellum; 6, Zingiber officinale (Ginger) probably.—P. C. P. 1, Jasminum revolutum; 2, Phillyrea angustifolia; 3, Elaeagnus pungens.—F. L. S. Stauntonia latifolia probably, widely different from Dioscorea.

SULPHURING VINES: F. F. We would counsel you not to use sulphur by burning it in the vineries, as although in small quantity it might not affect the woody portions of the plants, the buds would suffer. The precise quantity of sulphur that may be ignited per cubic foot of inclosed air in ainery without injury to the Vines, and yet be capable of destroying insect life, has not been ascertained.

THE

Gardeners' Chronicle.

SATURDAY, DECEMBER 25, 1897.

THE DATE PLUMS, OR KAKI FRUITS OF JAPAN.

A NEW fruit of good quality and ornate appearance is pretty sure of a welcome from those interested in fruit culture generally, and the wonder is that the brilliant Kaki fruit of Japan (*Diospyros Kaki*) in variety has not been seen more frequently in our gardens and at our fruit shows at this time of the year.

Of course, the tree has been cultivated in gardens here and there throughout the country, and our friend G. F. Wilson, Esq., F.R.S., was successful in obtaining ripe fruit in his well-managed and productive orchard-houses some years ago. (See *Gardeners' Chronicle*, 1875, p. 777, fig. 158.)

When Mr. F. Moore of Glasnevin and myself made a little tour in South France, North Italy, and Switzerland in 1892, one of the most remarkable of all the public gardens we saw was the Acclimatisation Botanical Garden at Hyères, near Toulon, with its Bamboos and Agaves and rare Palms in the open air, under a blazing sun, set in a cloudless sky.

We wandered about alone, for it was the sacred siesta-time with the officials and gardeners, and gazed delightedly on the blue Agaves, the feathery plumes of Bamboos, *Arundinarias*, *Phyllostachye*, &c., and for some time were quite non-plussed in our attempts to recognise our old friend the *Laurustinus*, so disfigured was it by the burning sun and red-spider. A fine specimen of *Brahea Roezli*, perfect in health, and blue rather than glaucous in colour, delighted us; but of all the novelties, nothing perhaps struck us more forcibly than a plantation of different varieties of *Diospyros Kaki*, young and vigorous, in the open air, and laden with handsome fruits. The trees were grown as standards, and in general appearance looked like large-leaved Greengage Plum-trees, laden with green, yellow, orange, red, and orange-crimson Tomatoes. The difference in size and colour of the fruits, being due in part to the particular variety, and partly to the age and position of the fruit itself on the tree.

The Kaki, or Date Plum, is one of the most popular of all Japanese fruits in its season, and is also highly appreciated by the Chinese. My first experience of it as a dessert fruit was made in Singapore, to which part it is brought down, I believe, by ships from Hong-Kong or Shanghai. In China and Japan, this fruit is almost as variable as are the Apples and Pears of our own gardens, the result, no doubt, of a long course of selection, seminal reproduction, and intergrafting on the part of these oriental horticulturists.

Now-a-days, however, this very distinct and handsome fruit tree has come from the flowery lands of the Orient to our South European gardens, and both French and Italian nurserymen offer collections of all the best fruiting kinds, some fifteen or twenty in number, at a very moderate price.

When, at the instigation of Dr. E. Perceval Wright, the Professor of Botany in Trinity College, Dublin, Mr. Moore and I visited Chevalier Ross in his fine old Palazzo Poggio Gherardo, high up above Florence, on the side near Vallambrosa, we saw there a plantation of very choice young and healthy trees. These are now in full bearing.

The two varieties I send differ in size, shape, and in flavour, the larger one ("Giboushin") being rich orange-yellow, as large as a medium Apple, and marked with sutures, as in the *Diospyros Kaki* var. *costata*, as figured by Carrière years ago in the *Revue Horticole*, and which was one of the first kinds to fruit in French gardens. This variety is as a rule, seedless, though, in this respect, individual fruits may vary even from the same tree. The smaller variety (*Isurunoko*) is smaller, with fruits of a rich shiny crimson-red, like a Tomato; it is rounded, without costae or sutures, and bears four to eight seeds embedded in its rich apricot-like pulp. In flavour the fruit, when soft, or "blotted" properly, tastes like a delicious conserve of Plum, Apricot, and Melon combined into one of Dame Nature's best of macedoines.

For several years past Dr. Wright has received at least one consignment of Kaki fruits from Poggio Gherardo, and this season the fruits seemed finer and more abundant, and of more exquisite flavour than before. To me, Poggio Gherardo, cool and white on the hill-side, standing amidst its Olives and Vines, and Fig trees and Palms and Oleanders, will always be a happy and grateful memory. Apart from the genial humour, hospitality, and generous good nature, which the Chatelaine dispenses to the passing stranger, as well as to her own friends, it would not be easy to forget its artistic charm, the sunlight and shadows which play around its time-honoured walls, the water Lilies and Nile Reeds in the splashing fountain-basin, the lizards that flit amongst the Caper blossoms that dangle from the sloping grey wall. The doves and the song birds even are happy near the roof here, while far below are the miles and acres of red-tiled houses, the great Duomo of Brunelleschi, the campanile of Giotto, the Palazzo Vecchio, past which flows the Arno, every inch of the great city sacred to the memory of Savonarola and Romola, who lived and loved and died in Florence when it was a city fit for kings to admire.

The *Diospyros Kaki* or Loti fruits of Japan, as I said, really deserves a place in English gardens. In the south and west, near the sea, it might thrive and fruit in the open air. Even as far north as Newry, co. Down, Ireland, I know of a plant that has grown for the past ten or twelve years on a sheltered and snug wall. In the Isle of Wight and Hampshire, in Devon and Cornwall, in south and west Ireland, and even in sheltered spots far up the west coast of Scotland, I should expect this tree might thrive with but little protection. It is as a greenhouse or orchard-house fruit, however, that it more especially deserves attention; and as the little trees are now offered cheaply by French and Italian growers, there is ample opportunity for trials being made by those interested in comparative novelties of this kind. Dr. Wright is so interested in the matter that

he has adopted the practical course of obtaining specimens of the trees, and has distributed them amongst the gardens in Dublin and Wicklow, where there is a prospect of their success; and he was fortunate in obtaining strong and healthy little trees, well engrafted, from Fratelli Ingegnoli, 54, Corso Loreto, Milan, who offers a collection of fifteen choice varieties, by parcel post, for 35 lira (frances). F. W. Burbidge.

THE LOST DAHLIA.

THE following extracts from an article by Miss Mitford in *Chambers' Edinburgh Journal* for January 7, 1837, may fittingly be reproduced in this year of Jubilee, more especially because the Mr. Sutton therein mentioned is the Martin Hope Sutton who is still among us, and well remembers the incident mentioned:—

"The autumn before last, that is to say, above a year ago, the boast and glory of my little garden was a Dahlia called 'Phœbus.' How it came there nobody very distinctly knew, nor where it came from, nor how we came by it, nor how it came by its own most appropriate name. Neither the lad who tends our flowers, nor my father, the person chiefly concerned in procuring them, nor myself, who more even than my father or John take delight and pride in their beauty, could recollect who gave us this most splendid plant, or who first instructed us as to the style and title by which it was known. Certes! never was blossom."

"We then visited the nurseries, from Brown's, at Slough, a princely establishment, worthy of its regal neighbourhood, to the pretty rural gardens at South Warnborough, not forgetting our own most intelligent and obliging nurseryman (Mr. Sutton of Reading—Belford Regis, I mean), whose collection of flowers of all sorts is amongst the most choice and select that I have ever known; hundreds of magnificent blossoms did we see in our progress, but not the blossom we wanted."

"Learnedly did I descant with the learned in Dahlias over the merits of my lost beauty. 'It was a cupped flower, Mr. Sutton,' quoth I, to my agreeable and sympathising listener (gardeners are a most cultivated and gentlemanly race); 'a cupped Dahlia, of the genuine metropolitan shape; large as the Criterion, regular as the Springfield Rival, perfect as the Mary, with a long bloom-stalk like those good old flowers the Countess of Liverpool and the Widnall's Perfection. And such a free blower, and so true! I am quite sure that there is not so good a Dahlia this year. I prefer it to Coriune over and over.' And Mr. Sutton assented and consoled, and I was as near to being comforted as anybody could be, who had lost such a flower as the Phœbus."

Eventually the lost Dahlia was found on a manure-heap in the corner of a field a mile away from the garden in which it originally grew. Phœbus is gone, Miss Mitford has departed, but Martin Hope Sutton happily still commands our respectful appreciation.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM CRISPUM SURPRISE.

THE last number of the *Semaine Horticole* contains a page illustration of this variety, remarkable for its short broad segments, marked at its edges with a row of small dark lines, after the fashion of a Picotee.

CYPRIPEDIUM DAUTHIERI.

Mr. Ross obligingly sends us from Florence a flower of *Cypripedium Dauthieri*, curiously distorted. The plant came from a seed-pod, from which also originated a pale and a dark variety of *C. Dauthieri*, together with *C. Dauthieri Rossianum*. In the malformed flower first mentioned the floral axis is twisted, the ovary is wanting, there are two sepals standing

right and left of the centre of the flower, and within these two lateral petals, so diverted from their original position as to be obliquely placed, or nearly front and back, as regards the axis. The column has three perfect anthers, but neither staminode nor stigma.

ODONTOGLOSSUM CRISPUM.

Mr. De Barry Crawshaw kindly puts at our disposal a spike of *O. crispum*, in which all the flowers are distorted, and all in nearly the same manner. The pedicels are upturned, and bear three narrow sepals, three petals of nearly the same form and size; the column is twisted, the ovary abortive. Arrest of development is, of course, the cause of the deformity, but what caused the arrest is more than we can say.

that a lesser degree of heat and drier conditions should prevail at other seasons. The winter warmth of fruiting plants at Syon is 60° to 65° at night, the lower one being probably the better one generally, as the plants grow away freely in the spring, so that the flowering period is past during May or June, with sufficient length of time to allow the pods to ripen in warm weather. The *Vanilla* is a climbing Orchid, which sends out numerous fleshy roots that lay hold of damp surfaces, as the walls or woodwork. From observation made, I am not sure which affords the best results, a wall or a trellis. I think the largest pods come from plants attached to a wall, and earlier ones and in greater quantity from plants on wire supports. It is mostly a matter of fancy; still, few

of the plant is done once or twice daily, according to the weather, and the paths are damped oftener. This is the kind of treatment afforded to old or established plants, but it is very necessary to overhaul the stock of plants yearly, there being a tendency in the plant to much top growth, and to get bare at the bottom, which, if not counteracted, would rob the plant of its roots and end in poor growth and a straggling form of growth. In December, or early in January, some of the upper growths are taken down and placed lower in new material, where they soon make rapid progress, and fruit abundantly the next season. The size of such growths as are selected for planting is of no consequence, as pieces of from 4 to 6 feet in length grow well, and the stronger they are the

CULTIVATION OF VANILLA PLANIFOLIA.

"VANILLA" is not a difficult plant to grow, although the fertilisation of the flowers so as to get pods is not understood by many gardeners. The figure given at p. 307, together with the instructions thereon of the method of securing pods, gave the needful information. I gladly act upon the Editor's suggestion in regard to sending a note on the methods practised for many years at Syon; only last year an additional space was allotted the plant in a new house, and I hope that better results will be obtained than in the old one. I may here state we had losses owing to the break-down of the heating-apparatus in February, 1894, in a time of severe frost, which occasioned the loss of a large houseful of these plants, and the weakening of others. We have now made up our losses, and have the promise of a full crop of pods next season. I need scarcely mention, that to grow *Vanilla planifolia* successfully stove-heat is essential, and more especially whilst in active growth, say from 65° to 70° at night, and a high day temperature, bearing in mind

kinds of plants are at the same time more ornamental and useful. In shade the plant grows well, but gives no fruits. The maturing of the stems is a point of importance, as without it no pods are formed. The plant does not rest on the completion of growth all the winter, but makes some little progress, and the roots being fleshy, should not be starved, and they are active if the growth has not been well matured before the end of the summer or early in the autumn. Two years ago a large house was planted at the front with *Musa Cavendishi*, the temperature for which just suited the *Vanilla*, it being, of course, lower and drier in the winter, and not shaded, and having a large back wall; this was covered with plants of *V. planifolia*, which grew finely. There was a wide walk in the front of the wall, and this was utilised by some large *Nepenthes*, which needed shade. The result was that the back wall was also shaded in the summer, and no crop of pods was obtained, *Nepenthes* and *Vanilla* not doing well together.

The *Vanilla* is started early in the New Year by raising the temperature to 65° to 70° at night, with good rise in the daytime by sunheat to 80°, and the houses shut up early in the afternoon. The syringing

better. It is advisable to place new material to root in yearly, as the old gets sour in a year. The best pods were for many years produced in some glass-houses that were 30 feet high, where the *Vanilla* were attached to the transverse partitions, the houses facing the South, and not shaded at any time. Here the growth became well matured, but few fruit were produced at the base of the plant. This, however, is not the case on walls that are always exposed to the sun.

The plants make good growth in a mixture of fibrous peat, small portion of sandy, fibrous loam, and plenty of charcoal, crocks, and sphagnum-moss. The loam, however, should not be used in very moist houses. A border of 15 inches in width and depth half filled with drainage materials, suits the *Vanilla*, as no plant goes sooner wrong in an ill-drained compost, it being like most Orchids, epiphytal, and the usual rules hold good after root-disturbance. Red-spider should not be allowed to infest the leaves, or these will get first yellow, and finally black. Young stock is best raised from shoots taken off in the early spring, and these may be grown in pots for a time. When a plant is flowering, overhead syringing should

cease, and air may then be given, but not so as to impinge on the plant. The illustration in the *Gardeners' Chronicle*, p. 307, makes it very plain how fertilisation is effected, and it should be closely examined by those who desire to excel. A pod takes from three to four months to ripen, and the precise time to gather it is indicated by the tip turning brown; and if it be not then gathered, it will open, and decay set in. The pods should be placed on a shelf for a few days so as to dry the outer, covering if it be not quite ripe, and then folded in tissue paper and placed in a close drawer. Pods will keep in good condition for years. The present is a good time to commence the culture of this plant. *G. Wythes, Syon Gardens.*

to the flowers unfolding, so as to form what is called a "good show." The consequence of this practice is, that shoots that will form the cuttings, become blanched, and hardly fitted to afford suitable cuttings. Not an instant longer than is necessary should the plants be kept in this crowded state; but as soon as the flowers are cut or faded, the stems should be cut down to within 1 inch of the soil in the case of those varieties which throw up shoots freely. Shy growers should not be cut back closely, as these usually throw out shoots from the stems at some distance from the base. These latter do not certainly make the best cuttings, but have to be made use of in lieu of better ones. Let the pots of stools or roots be stood close to the glass in a cool, airy greenhouse, so as to

them it is necessary that the stems be perfectly matured. The large misshapen blooms frequently observed have been produced on immature stems. The true globular incurved flowers, so desirable, yet so seldom seen at the present time, can only be obtained from plants that have a long season of steady uninterrupted growth. Strike the cuttings early, and let the plants grow steadily, without having recourse to fire-heat at any part of the year. The best kind of cutting is that which is found some distance from the stem of the plant, which gives promise of free uninterrupted growth, and has no visible sign of a bloom-bud in the point of the shoot. The cuttings should be 3 inches long, firm, not sappy in texture, and be cut square across below a joint.

FIG. 131.—A BREAK OF NARCISSUS IN BLOOM. (SEE P. 447.)

(From a Photograph by Valentine & Sons, Dundee.)

FLORISTS' FLOWERS.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

SCARCELY are the flowering-plants out of bloom, than preparations for another year's campaign have to be undertaken. The first matter which claims attention should be the revision of the list of varieties, for even in small collections some of them should be discarded, and better ones purchased. The increase of varieties is so large and constant nowadays, that none but the best in each section need be retained. The first matter which should have attention, is the providing of suitable shoots to serve as cuttings, for there is a very great difference as regards the plants raised from good or bad cuttings. Weak shoots cannot be expected to make as good plants as strong ones, and a good start is, therefore, of great importance. Large, high-class blooms for exhibition, as well as for the decoration of the conservatory or greenhouse, seem to be desired by most gardeners nowadays. The plants, as a rule, are restricted to three blooms each, and placed close together previous

enable them to gain that degree of strength and stockiness so desirable in a good cutting. Afford water sparingly—just enough to keep the soil moist; too much induces a paleness in the leaves, which should be avoided.

In some instances it will be found that the shoots spring up from the roots so thickly as to crowd each other, and become weak, rendering a timely thin-out necessary. Close watch must be kept for aphides, green and black, that are apt to infest the succulent shoots, crippling the leaves, and thus retarding growth. To destroy these pests, let the plants be fumigated on two successive nights with tobacco, or dusted with powdered tobacco. The shy varieties may be induced to grow at the base by the aid of mild bottom-heat in a warm house, the stems being syringed daily with tepid water.

The best time to put in cuttings so as to obtain fine blooms is the present or early in the new year, as by so doing the growing season is made as long as possible. If cutting-making is deferred till February or March, a firm matured growth cannot be obtained in a natural manner; and in the case of the incurved Chrysanthemum

Some growers cut out the buds or eyes from the lower part of the cutting, to prevent the growth of suckers in the summer; but this is neither necessary nor wise, because the production of suckers in a proper manner does not interfere with the well-being of the parent plant; and where is the stock of cuttings to come from for another season, if such strict measures are taken to prevent their growing at all?

Under handlights, or in a propagating-frame in a house having a temperature of from 40° to 50°, is the best place to strike the cuttings in. These should be placed on the side stages of the house as near to the glass as possible. Means should be taken to have the handlights as nearly air-tight as possible, as a means of preventing the flagging of the leaves. I find roots are more quickly formed under these conditions than when the cuttings are placed on shelves near to the glass in an ordinary greenhouse, where being greatly exposed to the air the leaves quickly flag. A layer of coal ashes at the bottom of the handlight forms a level moist base on which to stand the pots. *E. Molyneux.*

(To be continued.)

WEST INDIAN PRODUCE.

OUR friends engaged in the sugar industry, and concerning whom so much has been said and given in the way of advice, would appear to be endeavouring to work out their own salvation from that ruin which but a few months since appeared to be imminent. Advice received from St. Vincent, from Mr. Drayton, shows that improvement is being effected by economies; and it said that, although the colony is passing through a severe crisis, no one who has a knowledge of the resources of the island can doubt that, if a radical change is made in the existing local conditions, which retard its progress, there will be a gradual return of prosperity. It is affirmed that, with a more equitable distribution of the land, a proper system of roads, provision for rapid and safe transport of produce to suitable markets, and a decentralisation of the interests, both public and private, now concentrated in Kingstown, a future perhaps not of great affluence, but certainly of solvent prosperity, lies before this unfortunate possession of the Crown. Speed the time.

THE PRESERVATION OF FRUITS BY VAPOUR OF ALCOHOL.

EXPERIMENTS were made in the fall and winter of 1894 by Monsieur A. Petit at the National School of Horticulture of Versailles (France), in the preservation of Grapes by exposure to the vapour of common alcohol, which, according to report, gave very striking results.

Briefly, the method was this:—Freshly-picked Grapes were placed thinly upon trays of wood-shavings, in order to offer freer access to the alcoholic vapour. These trays of fruits were placed in a large cellar closet, which could be conveniently and securely (not hermetically) closed. A small vessel of alcohol was left uncovered in the room, and the ordinary evaporation from this satisfied the purposes of the experiment. The conditions of temperature and moisture were purposely made the most favourable for the development of mould fungi. Some similar fruit was at the same time placed under the same conditions, with the exception of the alcoholic protection, so as to serve as a check.

The experiment was begun on October 31. On November 20 the Grapes in the check were for the most part rotted and covered with mould. In the case containing the alcohol, on the contrary, the Grapes looked as well as ever—quite firm, not shrunken, and totally free from mould; they had no bitterness or bad taste. On December 7 the Grapes in the case with alcohol had still their fine appearance, though there were one or two small brown spots to be found. On December 24 there were only a few small spots of mould. The Grapes were referred to the judgment of several persons, who unanimously pronounced them very fine. The stems remained perfectly green, and the fruits retained their firmness, their volume, and above all, their flavour. In a word, they showed all the qualities of freshly-picked Grapes.

These statements are quoted from the report of Mr. Petit, made in February, 1895. This report immediately attracted wide notice, both in Europe and America. The first to test and report the method in this country was Goff. His experiments were made with Plums, and showed "that alcoholic vapour is an effectual preventive of the common mould or moulds in a damp atmosphere; but the vapour did not prevent, except for a limited time, if a further change within the fruits that destroyed their value."

The first opportunity found by the present writer for a trial of this method of preservation came May 20, 1896.

Beginning at this date six experiments were made, and the conclusions arrived at were as follow:—

Vapour of alcohol in a closed space will prevent, more or less, the growth of the fungi and bacteria which usually hasten decay. To be effective it must be present in some appreciable quantity. If present in a considerable quantity, the development of fungi

and bacteria may be wholly prevented for several days, or even weeks; but in this case the fruits, especially those with soft flesh, absorb enough alcohol to render them very disagreeable to the taste. The fruit also deteriorates in colour and texture. Although the growth of fungi and bacteria is prevented, other processes of decay seem to be hastened. The method seems to be best adapted to the preservation of Grapes, and it is probable that with sufficient experimentation upon details it might be made practically effective for special conditions. It is thought that this method might be put to practical use in occasional cases for the preservation of some other fruits for a very short time. Thus, Strawberries or Raspberries might be placed in a refrigerator for three or four days with a small open vessel of alcohol, and be preserved in better condition than without the alcohol. F. A. Waugh, in Tenth Annual Report, Vermont Experiment Station.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By W. H. POPE, Gardener, Highclere Castle, Newbury.

Garlic and Shallots may be planted in a sunny situation, and on a rather light, open soil, if possible, planting the cloves shallow in small drills, and about 1 foot apart each way. In heavy land the drills should be 4 inches deep, and filled before planting with light soil.

Protecting Early Broccoli, &c.—Where the early Broccoli are turning in, it is well to go over the plantations once or twice weekly, and break down a few of the leaves over the heads, or if large enough to cut for use, storing these in a cool shed for a week or ten days. It is advisable, if hard weather seems likely to set in, to cut all heads that are of a useable size, and place them in a cellar out of the reach of frost. The varieties Sutton's Christmas White, Vanguard, and Superb White, are now forming heads, and in succession to Veitch's Self-protecting Autumn Cauliflower and Michaelmas White Broccoli, and those will probably keep up a supply of heads till March. This season has been an exceptionally favourable one for vegetables, excellent Cauliflowers being still procurable from the open ground, as also Lettuce, Endive, &c. At the New Year we may have a fall in the temperature, rendering it necessary to put some kind of protection over beds and rows of Parsley, Celery, &c., and it will be prudent to get materials ready for use whilst the weather is mild. There is no doubt that owing to the late period to which the growth of vegetables has extended, they will be much cut up by hard frosts.

Forcing.—Successional batches of Asparagus, Sea-kale, and Rhubarb, should be got in, in quantity corresponding with the demand. Afford tepid water in abundance to these plants as may be required, the lack of it being the cause of much inferior produce. Light and ventilation are necessary to Asparagus unless the tops are preferred in a blanched state. Hot-beds of prepared manure may now be made up for forcing Potatoes, Carrots, and Radishes. It is a common economical practice to sow Radish seed thinly betwixt the rows of Carrots, and to sow broadcast. This is not the best manner of doing it. A better one is to take two or three seeds between the finger and thumb, and slightly squeeze them in the soil at about 4 inches apart, also in rows; and a still superior method is to have frames or pits devoted to special crops, as it is seldom that interlining has good results. Good varieties are Early Frame, and Sutton's Forcing. French Forcing Carrot should be sown for the earliest crop, the drills being drawn at 1 foot apart if alternated with Radishes, otherwise 9 inches will suffice. When the young plants appear, apply fresh soot to check the ravages of slugs; also set traps for these creatures. Thin the seedlings to 2 inches apart when they have got large enough to handle. Roots of Mint and Tarragon may continue to be placed in mild heat. So in warmth Mustard and Cress at weekly intervals, placing that which is up in cooler quarters. Preparations for sowing Onions may now be made, storing deep in turfy loam mixed with a good quantity of leaf-mould in a frost-proof shed. The seed may be sown in the second week in January.

Plants under Glass Protection.—Cauliflower, Endive, and Lettuce growing in garden-frames or under handlights or cloches, should be freely ventilated in mild weather, removing the frame-lights, hand-glasses, &c., by day, and affording air by night.

Testing Seeds more than One year Old.—The seed-room should now have a general cleansing, and any seeds left over from last season sorted, and those that are not likely to germinate in considerable numbers thrown away. Seeds of Melons, Cucumbers, Parsley, Celery, &c., may be reserved for future sowing, and others about which there may be doubt should be put aside for testing as soon as a hot-bed is available. The seeds of Peas and Beans, if more than one year old, should always be thrown away.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Hot-growing Species.—*Calanthes* of the vestia section form at this season a principal attraction in the Orchid-houses. They require a period of thorough rest, and immediately the spikes are removed place the plants on a dry shelf close to the roof-glass. Coming from very hot countries, these *Calanthes* should be kept in the warmest house, even when resting, and water may be entirely withheld until the plants have been repotted in the spring. Before removing the plants to their resting quarters, each pseudo-bulb should be carefully examined and cleared of the white and brown scale which commonly infest them. The pretty *Eulophia guineensis* should be rested, and treated like the *Calanthes*. Do not forget the *Thunias*, although they are resting. The plants have now cast their leaves, and where eight or ten are grown in one pot, as is generally recommended, the bare stems should be tied upright to neat sticks at even distances apart, so that each may obtain its equal share of light. The bulbs from which the current season's stems have sprung should be cut down to their base. It is perfectly safe to rest the *Thunias* with the deciduous *Dendrobiums*. If such species as *Cyrtopodiums* are grown, it will be seen that some of the growths are nearly completed, and the plants may therefore be gradually dried off, and water entirely withheld when the current season's growths are finished, or they may fail to rest. The plants require the highest temperature available during active growth; but immediately water is withheld, they should be placed with the *Thunias*. *Cyrtopodium Andersonii*, *C. St. Ledgerianum*, and *C. punctatum* are handsome species. Like *Chysis* and the *Angulos*, these plants produce their flower-spikes soon after the new growth commences, and should therefore be very carefully watered when growth has commenced until the spikes appear. If kept too moist at the roots at such period, the growths will become vigorous, but no flower spikes will be seen. *Habenarias*, too, though resting should be examined carefully every week, and any that are dust-dry may be given a slight sprinkling of water on the surface of the soil. The warm-house is the best place for them. Plants of *Odontoglossum citrosum* that have completed their growth should be suspended close up to the glass in the resting-house. After removal, the plants should be kept quite dry at the root, and though the bulbs will shrivel, this will not injure the plant in the least; and when the flower-spikes appear, and moisture is afforded, the plants will quickly regain their normal condition. Under such treatment our plants rarely fail to flower abundantly; even the smallest growths produce flower-spikes. Owing, probably, to climatic conditions, it will be observed that a few plants have already commenced to grow again, but if they are rested and treated as above-described they will make little or no further progress at present. *Peristeria elata*, generally known as the Dove Orchid, succeeds best in a stove-temperature, but immediately the large pseudo-bulbs are mature, the drier atmosphere of the Cattleya or Mexican-house is the best place for it. The plants require a long and complete rest, without which it may fail to flower. *Vandites* is exquisite when in bloom, but many growers have difficulty in getting it to flower satisfactorily. To obtain good results do not subject the plants to the severe drying treatment often advocated, which causes the terete leaves to shrivel, and the lower ones to drop. Our plants are now at rest, and occupy a cool position in the Mexican-house, and they receive sufficient water to keep the stems and leaves plump at all times, and they thrive and bloom profusely every year. The same kind of treatment as regards moisture is afforded to *V. Hookeriana*, but it is grown and rested in the stove.

Temperatures.—The temperature of the cool or *Odontoglossum*-house, when finishing up for the night, is about 50°, falling 2° or 3° by the morning. The atmosphere in this house is nearly always within 3° of saturation point. Each of the divisions should

also be covered with mats in like manner, so that the amount of fire-heat is by night reduced to a minimum. It is always advisable to remove the coverings in the morning as soon as it is light, or immediately the temperature commences to rise. It is very necessary at this season that each house should become dry about noon. The houses at noon are at their maximum temperatures, and it is at this time that ventilation should be afforded, but air should not be admitted in such quantity as will cool them. The majority of Orchids delight in fresh air, but it must not be too cool. To warm the external air before it reaches the plants the bottom ventilators should open immediately opposite and close to the hot-water pipes, the inside of which should be covered with perforated zinc, which will allow the air to pass in small currents, and passing in among the pipes is thus made warm.

PLANTS UNDER GLASS.

By G. H. MAYOOCK, Gardener, Luton Hoo Park, Luton.

Double Primulas.—If these plants have been well cultivated, they will soon produce an abundance of flowers. Keeping the pots resting on a cool base with only sufficient fire-heat to dispel all damp from the atmosphere, which must be kept in a buoyant state. Very careful watering is necessary, and such plants that may have been potted rather too low should not be allowed to suffer from the water lodging in the axils of the leaves. On the other hand, if any plants were not potted sufficiently deep, these may suffer from the thread-like roots at the surface becoming dry. Weakly plants may be assisted with weak manure-water, but if the stock is robust, the plants will do best with clear water only.

The Forcing-house.—Batches of bulbs and plants intended for forcing should be placed in heat at such intervals of time as the establishment requires. If bulbs were potted-up according to previous instructions, they will in most cases be fit for the purpose. *Lilacs*, *Thorns*, *Solomon's Seal*, *Spireas*, *Dielytra spectabilis*, *Guelldres Roses*, *Azaleas* in variety, *Lily of the Valley*, and *Daffodils*, will all be useful. It is not yet too late to pot up additional batches, if it is apparent that the stock is likely to be insufficient, but this is more applicable to plants, not bulbs.

General Work.—Examine at intervals all bulbs that are resting, and remove any that may show signs of decay. Should any bulbs be resting over fires or other excessively hot, dry places, they may require water occasionally to keep them firm. The seed catalogues have commenced to arrive, and orders should be prepared and despatched to the nursery-men at once, that everything may be in readiness before the busy season of spring.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, late of Eastnor Castle, Leobury.

Pot Vines.—These Vines, now fast breaking into leaf, will require much attention in order to keep them growing and healthy. If not already tied up to their supports, they should be secured to them without delay. Let the bottom-heat be kept steady at the point advised in earlier Calendars, adding fresh materials as may be required. Be sparing with overhead syringing, but damp the floors and walls; and afford ventilation in small amount about noon on mild days, but do not cause draughts in so doing, and if air be afforded with care, growth will be much benefited. Examine the Vines twice daily in order to ascertain the state of the soil as regards moisture, affording water only when it is absolutely necessary; on the other hand, do not let the soil get too dry.

Permanent Vines.—Those which are started must be treated as has been advised, closing the vinery early in the afternoon, and forming a heap of stable litter and leaves in the house. If the soil of the border is dryish, afford water plentifully at a temperature of 85°. The outside border should be protected by a thickness of 1½ to 2 feet of stable manure and leaves previously fermented, covering this with shutters, spare lights, supported above the litter, so that the air may circulate freely underneath. The borders of Vines which still carry fruit may likewise have protection of litter and a covering like the early vinery. It is the better practice to bottle all Grapes at the end of the year and throw open the vineries, except in very hard weather, taking care that the water is kept slightly warm in the pipes. All Vines that have borne a heavy crop should be afforded liquid manure in quantity, especially the inner borders, and the narrower or shallower these are the more manure-water should be afforded. Grapes in bottles should be examined twice a week.

Early Peach-house.—The trees in the early-house are fast coming into bloom, requiring close attention to be paid to the ventilation of the house, so as to secure a good set. In mild weather air may be safely admitted in small quantity by the upper and lower lights if heat be admitted to the hot-water pipes, so as to have a night temperature of 50° to 55°, and by day of 60° to 62°. When the blooms begin to open, slightly damp the floors, &c., about 2 P.M., and stay the use of the syringe. If ripe Peaches are wanted in the month of June, a house may now be started; and in regard to this, all previously given instructions hold good, not forgetting to afford the borders a thorough wetting with warm water, this applying also to all fruit-tree borders that are inside the glass-houses. Push on with the pruning, cleaning and tying of all trees in the later houses before the flower-buds move, and keep the trees at rest as long as possible.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Unnailing Peach, Nectarine, and Apricot Trees.—In order to retard the flowering period, the nails and shreds and twigs which have been employed to keep the young growths close to the wall should be withdrawn, which will liberate the branchlets from the influence of the brick walls, which conserve and radiate the warmth from the sun's rays. Collect the nails and shreds as the work proceeds, and subject them to fire. When cool put the nails into a fine sieve to separate them from the ashes, when they will be again ready for use. By the exercise of timely attention to this matter the prospect of securing crops of Peaches and Nectarines from unprotected trees upon walls is greatly increased. The pruning and nailing of the trees can be done a week or two before the flowers begin to open, so that there will be plenty of flowering-shoots to choose from when pruning.

Pruning and Nailing.—The pruning, training, and nailing of other kinds of trees than those mentioned above should be pushed on during open weather. In the event of frost occurring, such work as wheeling manure on to fruit plots, cropped between the trees with vegetables, and between rows of Raspberry-canes and Strawberries as a mulch. The training and nailing of trees may be proceeded with after breakfast, when the sun has obtained sufficient power to enable those engaged in the work to perform it in comparative comfort. In the afternoon, the declining temperature may render the resumption of the wheelbarrow, or other suitable work necessary.

The Labelling of Fruit-trees.—It is very important that the names of all kinds of fruit-trees, or numbers corresponding to the names in the fruit-grower's book, should be re-written before they become unrecognisable upon the labels. There are many kinds of labels in commerce at the present time. Zinc, written upon with indelible ink (white vitriol); copper, inscribed with a mineral pencil, are both good in their way. They should be secured to the individual trees with fine copper-wire, being careful to leave sufficient room in the ties to prevent them cutting into the bark within the next half-a-dozen years. Labels made of well-seasoned red deal, properly painted, and written on with a hard black-lead pencil, and secured in the manner recommended above, still finds favour with many fruit-growers, including the writer.

Fruit Room.—Carefully watch the Apples and Pears on the shelves in the fruit-room, and remove blemished fruit before they impart infection to others. Apples and Pears keep well in a room having a temperature ranging between 40° and freezing-point (32°). Walnuts, Filberts, Cob-nuts, and Chestnuts stored away in jars and vaults must be made secure against the attacks of mice.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Drogheda, Maidenhead.

Plants to grow under Trees.—The most commonly planted species for this purpose is probably the Ivy, and the larger leaved varieties are usually chosen. In localities where the soil is not of a heavy clayey nature, two satisfactory plants for the purpose are *Gaultheria Shallon* and *Andromeda Catesbei*. Both are North American evergreen plants, growing from 18 inches to 3 feet in height, but when growing under trees they seldom exceed 2 feet. When once established they increase and spread rapidly over bare spaces, and in woods afford a cover for game. The *Gaultheria* also produces a number of Lily-of-the-Valley-like flowers spikes in May and June, and these are succeeded by handsome purple-black berries, which are freely eaten by the smaller birds and pheasants. Seeds of *Gaultheria* should be sown

in the open ground in early spring or as soon as ripe, but the quickest means of increasing the stock is by division, or rather by lifting the youngest rooted growths that are always found around the outer edges of established clumps. The young growths may be transplanted safely now while the weather remains open, and they become partially established by spring. *Gaultheria procumbens*, a dwarfier and rather more delicate variety, may also be used; it grows freely where the soil is peaty, or where naturally-made leaf-mould abounds. The *Andromeda* is of a closely-allied nature to *G. Shallon*, and requires similar treatment in planting, but rarely produces seeds. *Vincas* in several varieties are excellent subjects for forming a dwarf evergreen carpet under trees; *V. major* and *minor*, with the variegated forms, grow and spread quickly, and may be planted now. When planting under trees, the surface-soil should be broken up with a fork and fresh soil added if a sufficient depth cannot be obtained for planting without interfering unduly with the roots of the trees.

Carnations.—During frosty weather young Carnation plants are liable to become lifted almost out of the ground, and one night's frost is sometimes sufficient to do this, if the plants were not firmly planted. As soon as the ground is free from frost, tread the soil firmly around the plants. A 2-inch mulch of old Mushroom-bed manure or Cocoa-fibre refuse is a protection and preventive. Plants wintering in pots in cold frames should be kept well exposed, except during heavy rains and frost, covering the frames only just sufficiently to exclude the latter.

General Work.—Prepare soils for potting off and propagating various bedding-plants, and place them under cover, where they will become moderately dry. During inclement weather, all dirty pots should be washed and stored in their various sizes in a dry place. Crocks may be broken up, sifted into different sizes, and placed in tubs or bins. Sticks may be pointed, and tied up in sizes in convenient bundles; and pegs made for use in layering, &c. Wood-labels can be bought so cheaply, that their cost is much less than the labour and materials for making them; and old ones are not worth re-pointing for use a second time. Mowing-machines will not be required in use again for some time, and any necessary repairs required should be seen to at once. Where no repairs are necessary, the parts should be thoroughly cleaned, for which purpose paraffin is a useful help; afterwards smearing over all bright steel parts and the bearings with lubricating-oil or vaseline to prevent rusting.

THE DISCOVERY OF COAL.—According to a recent issue of the *Revue Scientifique*, a Belgian journal suggests that this year being the seven hundredth anniversary of the discovery of coal, should be appropriately celebrated. It appears that it was in 1197 that a blacksmith, living in Rue de Choque, Liège, found near Publémont a kind of black earth which he made use of as fuel, wood and charcoal being very dear at the time. This black earth was coal. The blacksmith's name was Hulloz from Plaineveaux, hence the name of houille given to coal. Authenticated documents further prove, says the *Journal des Fabricants de Papier*, the existence of coal-mines in full operation in the principality of Liège in 1228, and in Hainaut in 1229. The use of coal was not introduced into England until the beginning of the 14th century; it was only in 1340 that certain privileged manufacturers obtained the warrant to burn coal (this fuel being then regarded as injurious to the public health), and a century elapsed before it was generally used in houses. In France there was no further advance before the fourteenth century. The coal-fields of Roche-la-Molière (Forez) were open in 1320, and it was the Belgians who took the principal part in commencing operations in the rich basin of the North; the celebrated Ausin mine was discovered on June 24, 1734, by Pierre Mathieu, of Lodeluisart, as his tombstone in the church of that borough testifies. The first edict on mines which speaks of coal in France dates back to June, 1801. Among the other countries of Europe, Austria and Bohemia disregarded until the last century the rich coal-fields which they possessed among their mountains. It was then the Belgians, summoned at the advice of Prince Charles of Lorraine, Governor-General of the Austrian Netherlands, who, in 1757, began the first important investigations in Austria. North Germany, on the contrary, seems to have begun the exploration of its various large coal-fields about the year 1200; but the investigation of the Saxony, Silesian, and Ruhr fields was only developed in the present century.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SALES.

THURSDAY, Dec. 30. Continental Plants, Roses, Dutch Bulbs, Herbaceous Plants, Lilliums, &c., at Protheroe & Morris' Rooms.

FRIDAY, Dec. 31. Imported and Established Orchids at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—37.5°.

ACTUAL TEMPERATURES:—

LONDON.—December 21 (6 P.M.): Max., 39° Min., 35°.

PROVINCES.—December 21 (6 P.M.): Max., 49°, Valencia (Ireland); Min., 32°, Stornoway.

Large-fruited Perpetual Strawberry.

THE *Revue Horticole* of December 16 contains a coloured illustration and description, by M. H. DE VILMORIN, of a new Strawberry, called "Saint Joseph." This is a perpetual Strawberry, of erect habit, with large fruit, as successional in yield as an alpine variety. It was raised by the Abbé THIVOLET, Vicar of Clanoves, in the Department of Saône-et-Loire, and is said to be the result of a cross between an ordinary and an Alpine Strawberry. M. DE VILMORIN, however, doubts the occurrence of any true cross, as he finds no trace of the Alpine Strawberry in the new variety. The tendency to produce flowers in succession is common enough; as, for instance, in Vicomtesse Héricart du Thury and Belle Lyonnaise. This tendency, which in the varieties named is exceptional, though not infrequent, has become the regular condition in the new variety. Other instances of like nature have been previously observed, e.g., one recorded in the *Revue Horticole*, October 1, 1871, and in January, 1874; but this plant cultivated near Paris produced imperfect flowers only. The Abbé THIVOLET, by renewed fertilisations, effected between his first seedlings and free-fruited varieties, after ten years of experiment, succeeded in producing a variety with continuously-produced fruits of large size, the last of which ripened as perfectly as the first. M. DE VILMORIN has now grown this variety extensively for the last three or four years, and testifies that throughout the whole extent of the plantation the production of flower-panicles has been continuous, so that anyone with, say, thirty plants, could supply himself all through the season with a dish of ripe tasty Strawberries every morning. Abundant watering and good feeding are required to keep up the productiveness of the bed. The figure in the *Revue Horticole* shows that the flower-panicles are provided with leaves, whilst M. DE VILMORIN tells us that the runners themselves sometimes bear a panicle of

flowers. The fruit is of medium size, ovoid-conic, sometimes flattened and crested, and of flavour comparable to that of Vicomtesse Héricart du Thury. Such a variety will be useful for forcing purposes. It may also be pointed out that the edible part of the Strawberry is not the fruit in a botanical sense. It is not the direct product of fertilisation, but merely a swelling of the central axis or receptacle of the flower—a branch, in fact, bearing the true carpels or fruits, which we know as "pips" or "seeds" as so many side outgrowths. These, by the increase in succulence of the receptacle, become more or less embedded in it. The distinction recognised by every botanist from time immemorial, but generally ignored by the public and the gardener, is an important one nevertheless, because the conditions requisite for the ripening of the true fruits are different from those requisite for the growth of the receptacle. A so-called perpetual Strawberry may not necessarily produce a continuous succession of "pips" or seeds even if its receptacle expanded into a succulent mass, and therefore there is not such a drain on the constitution of the plant as might at first be supposed.

Not the least interesting feature attached to this new Strawberry is the connection of a De Vilmorin with it. In this matter, M. HENRI DE VILMORIN is carrying on an old family tradition.

OUR ALMANAC.—According to previous practice, we shall issue a *Gardeners' Chronicle* Almanac with our first issue in the New Year. In order to make it as useful as possible for reference, we shall be obliged if Secretaries of Horticultural, Botanical and allied Societies, or any of our correspondents, will send us immediate intimation of all fixtures for 1898.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, January 10, 1898, when the adjourned discussion on the paper read by Mr. F. PUNCHARD (Fellow) at the last meeting, entitled "The Royal Commissioners' Suggested Amendments to the Agricultural Holdings Act, 1883," will be resumed. The chair will be taken at 8 o'clock.

CROSS-BREEDING IN CEREALS.—We have from time to time commented on this subject, and have now to call attention to the experiments of Messrs. GARTON, as commented on in the *Cable* for Dec. 4. We first saw illustrations of their crosses at the opening of the Winchelsea House establishment, and were much struck with the advances made, though it must be admitted there were strong men before Agamemnon, and that cross-breeding in Cereals is not altogether a new subject, and can hardly be spoken of, as it is by our contemporary, as a "discovery." The Government were solicited to lend assistance, but they did not see their way to this, as there was no precedent upon which to act in such a matter. In these circumstances, the Earl of WINCHELSEA set a portion of his Sleaford estate at the disposal of Messrs. GARTON in order that they may continue their experiments. The results obtained by horticulturists on the same lines afford ample guarantee for similar progress on the part of agriculturists. It is claimed for Messrs. GARTON that the grain, in the case of Wheat, has been increased in size 40 to 50 per cent.; the quantity of gluten has also been increased. In Oats, varieties have been produced which give four or five times more than the ordinary varieties.

MÖLLER'S DEUTSCHE GÄRTNER ZEITUNG is to appear as a weekly journal from January next.

MUSÉUM D'HISTOIRE NATURELLE.—We have received a catalogue of seeds and living plants offered to public establishments by the museum. Application should be made to the DIRECTOR, 57, Rue Cuvier, Paris.

HOW TO CATCH SLUGS AND SNAILS.—M. HENSON, in the *Revue de l'Horticulture Belge*, recommends that small pieces of wood smeared on the under-side with lard or grease, and laid about the beds, form excellent traps for these destructive molluscs.

THE LATE MR. BATEMAN.—Among the notices of the late distinguished Orchidist (most of which we observe have been taken without acknowledgment, directly or indirectly, from our own columns), not one has alluded to the vigorous way in which he attacked a swindler, who paraded in the most audacious manner his wonderful novelties. Mr. BATEMAN'S "Museum Hullettium," in our volume for 1867, was a source of amusement to all but the dupes, and they were many, and of high degree; and, no doubt, it led to the removal of the culprit into a locality where it was impossible to grow the Münchhausen-like wonders, and equally impossible to proclaim their wondrous attributes.

SALE OF CYPRIPEDIUM BEEKMANNI (see p. 434).—To this plant an Award of Merit was granted, and a higher award would have been made had there not been a doubt expressed by some members of the Committee as to its exact parentage. The price for which the plant sold was 4000 not 400 francs. Our information came from a Belgian correspondent, and was not checked with our own previous report.

DUTCH HORTICULTURAL AND BOTANICAL SOCIETY.—At the meeting of this Society, held on November 27, 1897, at Amsterdam, the committee awarded First-class Certificates to Messrs. A. P. BOUWMAN & SONS of Arnhem, for Chrysanthemum Belle des Gordes, and for C. Milla. Léocadie Gentils; to Mr. W. VAN Veen of Leiden, for Chrysanthemum Lady Esther Smith, C. Mrs. J. Lewis, and C. Madame Gustave Henry. Certificates of Merit were granted at the meeting of October 9, 1897, to Mr. J. VAN HOUTEN of Hilversum, for a white sport from Chrysanthemum C. Harman Payne; and to Mr. A. G. M. RICHARD, of Naarden, for Yucca filamentosa bicolor. H. C. Zwart, Secretary.

NOTTINGHAM AND NOTTINGHAMSHIRE CHRYSANTHEMUM SOCIETY.—The members of the above society held their annual dinner at the Adjutant White Hotel, Hunger Hill Road, on Friday evening, 17th inst., to which about fifty sat down, Mr. D. WHITTINGHAM (president) presiding.

THE WEATHER-PLANT.—We have received various letters on this subject, which has again cropped up in the daily papers. There seems, indeed, to be no limit to human credulity, and the high and mighty seem equally liable to these infirmities as the poor and simple. Many of us, moreover, are troubled with short memories, else it would be remembered that, in compliance with the wishes of the PRINCE OF WALES experiments and observations were made at Kew by Professor FRANCIS OLIVER, the details of which are given in the *Kew Bulletin* for January, 1890, No. 37. We do not want to waste space by repeating the details of Professor OLIVER'S careful comparison of Mr. NOWACK'S forecasts with the actual results. In many cases, the "forecast" was made out after the event! A circular now before us gives a copy of the letter of introduction from the PRINCE OF WALES to the Director of Kew, but it entirely omits reference to the trials made at Kew to which we have above alluded.

CHRYSANTHEMUM CULTURE.—One great objection to the culture of Chrysanthemums, at least for exhibition purposes, is the length of time and the amount of attention they require to bring them to perfection—indeed, there is no end to it. Hardly have the flowers been removed than it is time to think of taking cuttings and starting afresh. Hence, there is much interest to Chrysanthemum growers in considering the method of culture followed by Mr. LYNE, as described in a recent number of our energetic contemporary, the *Gardeners' Magazine*. The method is briefly this:—After the flowering period is over, the plants are placed in a cold-house, or under the shelter of a wall. The pots are sunk, and arrangements made for protecting the plants in case of need. In the spring the plants are removed to a

warmer and lighter situation, where they speedily form compact and robust offshoots. These offshoots are taken off, and the cuttings placed in frames towards the end of May. In about ten days the cuttings will be rooted, and should then be gradually exposed to the air, repotted into thumb-pots, and ultimately into 48's or 32's, where they will flower at the usual time. In spite of the shortness of the time, the size and quality of the flowers are by no means impaired. A French journal claims precedence for M. CHOLET, of Lyons, which is only another proof of the value of the method for certain purposes, for had it not been a good one, our neighbours would not have been in a hurry to claim priority. The subject was discussed at the Chrysanthemum Congress held at Bourges in November, 1896, a report of which will be found in the journal of the French Society of Chrysanthemists, *Le Chrysanthème*. In that journal M. CALVAT, speaking of M. CHOLET's procedures, recommends it in cases where it is desired to have short compact plants for market-work, or the decoration of apartments. After all, there is nothing very novel in spring-struck cuttings, and where plants are hardy enough to withstand the winter, the advantage of striking the cuttings in spring, when risk from frost is over, and they will have all the benefit of increasing light and heat, is obvious.

"FLORA CAPENSIS."—It is not long since we had the pleasure to announce the recommencement of this valuable work, of which three volumes were published by HARVEY & SONDER. The work remained in abeyance till recently, when it was resumed, and botanists and horticulturists were enabled for the first time to get a collected account of the Cape bulbs, Aloes, and other Monocotyledons in which they are so much interested. The part now before us contains, among other Orders, the Comelynas and part of the Cyperaceae, by Mr. C. B. CLARKE; the Juncaceae, by Mr. BAKER; the Restiaceae, by Dr. MASTERS; and various smaller Orders by Mr. N. E. BROWN, Mr. ARTHUR BENNETT, and Mr. C. H. WRIGHT.

MARKET GARDENS AND FRUIT GARDENS.—From official records we learn that the area allotted to the culture of small fruit in Great Britain in 1896 was as follows:—

Orchards	32,000 acres
Market gardens	30,699 "
Elsewhere	13,456 "
Total			76,245 "

The acreage devoted to market gardens in Great Britain was 96,696 acres. The total acreage of orchards was 215,642. In each case there was an increase over the preceding year.

THE PUBLIC GARDENS AND PLANTATIONS OF JAMAICA.—The November issue of the *Botanical Gazette* (Chicago) contains a full account of the history of the Botanic Gardens of the island, by Mr. W. FAWCETT, the director. Jamaica affords an excellent illustration of what may be done by the practical application of botanical science to avert the ruin consequent on the failure (from fiscal reasons) of one crop.

HYBRID FERN.—Prof. J. B. FARMER, in the last part of the *Annals of Botany*, describes the peculiarities of a hybrid Fern raised many years ago in Messrs. VERRILL's nurseries by Mr. SCHNIDER. The parents were *P. aureum* and a variety of *P. vulgare* known as *elegantissimum*, which occurs naturally in Cornwall, and shows some tendency to revert to the common type. The spores from the Cornish variety were sown, and when the prothallia were developed they were planted inter-mixed with prothallia derived from *P. aureum*. The two sets of prothallia could not be sown together as the rate of growth of *P. aureum* is much more rapid than in the case of *P. vulgare*. Mr. SCHNIDER has repeatedly raised this hybrid Fern, so that no doubts are entertained of its hybrid origin. Professor FARMER details the structural peculiarities of the two parent forms and of the intermediate plant, one of the most interesting of

which is the sterility of the spores. The structure gives an opportunity for a discussion of the theories of WEISMANN, into which we cannot follow him.

"THE WEEKLY FLORISTS' REVIEW."—We have received a copy of the first number of a new American paper, devoted principally to Trade interests. Every subscriber who shall, in addition to payment of his annual subscription, remit one dollar to the manager, will be entitled to receive the dividends on one-tenth of a share of the stock in the company formed to publish the paper. The shares are at par value, 10 dollars.

VICTORIA MEDAL OF HONOUR.—At a meeting of the Council of the Royal Horticultural Society, held on December 14, it was decided to issue a diploma to all the recipients of the Victoria Medal of Honour. It was also unanimously resolved:—"That in the event of any recipient violating the conditions on which the Victoria Medal of Honour was bestowed, by using it for advertising or for the promotion of trade interests in any other way, the name of such offender shall be struck off the list."

HORTICULTURAL CLUB.—The usual monthly dinner and *conversazione* was held on Tuesday evening, the 14th inst., and was one of the most successful that has taken place for some time. The chair was occupied by Mr. Harry J. Veitch, and there were present beside the Rev. W. Wilks, Messrs. Philip Crowley, M. H. de Vilmorin, R. Milligan Hogg, J. H. Veitch, Henry J. Pearson, C. E. Pearson, Geo. Bunyard, Geo. Monro, J. Asbee, James Walker, G. Gordon, J. Sweet, A. Watkins, Peter Kay, A. W. Sutton, A. F. Barron, Geo. Paul, H. Wright. Mr. M. J. Garcia was the guest of the Club for the evening, and gave a most interesting address on the "Development of the Foreign Fruit Trade, and its Bearing on British Fruit Culture." A very lively discussion followed, in which Messrs. Geo. Monro, J. Walker, G. Bunyard, and others took part. A cordial vote of thanks was awarded to Mr. Garcia, and was carried with acclamation.

SOCIETY OF JERSEY GARDENERS.—The eighth annual dinner of this Society took place on Thursday evening, the 16th inst., at the Royal Yacht Hotel, St. Helier, Jersey, the chair being taken by the retiring President, Mr. A. Luxon, the company mustering altogether about seventy. The occasion was seized upon to present the President, on the behalf of the members, with a valuable gold watch in recognition of his great services during his period of office. The presentation was made by the Constable of St. Helier (Mr. H. E. LE V. DIT DURELL). The new President of the Society is Mr. ASHFORD, Queen's Road, Jersey.

EXCHANGE OF SPECIMENS.—Mr. C. K. DODGE, of Port Huron, Michigan, U.S.A., is desirous of exchanging dried specimens of plants with British or Irish botanists. The specimens are good, well-named, and the number of duplicates available for exchange is about 10,000. They are mostly from the vicinity of Lake Huron, near the Canadian frontier (province of Ontario).

NARCISSUS IN SCILLY.—Our two illustrations in the present issue almost explain themselves. The one, a field of the bulb farmer in a small way, with its rows of Narcissus in full bloom; and the young man with the basketful of cut blooms (see fig. 131, p. 443); and then the shed, with perhaps a glass roof, in which lads and lasses are busily engaged in sorting and bunching the blooms, cut probably the day before in a scarcely opened condition, but which have been expanded sufficiently for market purposes in a warm-shed or glasshouse (see fig. 130, p. 442). When packed in light wooden boxes holding a dozen or two dozen bunches, and addressed to dealers and salesmen in London and the leading cities of the country, they are ready for stowing on board the small steamer which makes the passage from Penzance four times a

week, beginning with a cut. or two, and reaching 30 tons. The weight of Narcissus flowers alone reached, in the present year, 500 tons. The trade in Narcissus seems to extend every year, so much do the beauty of colouring and gracefulness, and fragrance of some of the varieties, appeal to persons of all classes. The narrative of the introduction of the cultivation of these bulbs to the poverty-stricken islanders, by Mr. DORRIEN SMITH, less than a score of years ago, is known to most of our readers, so that recapitulation is unnecessary. In Scilly, we may remark, there is no winter and no summer, and it may be said that it is all spring or autumn weather; neither scorching heat nor biting frost. From November to May or June is the rainy season, and after June dry weather sets in. Plants from Japan, New Zealand, and Australia too tender to withstand the climate of the mainland, excepting in parts of Devon, Cornwall, and South-west Scotland, thrive here without protection, unless it be of an arboreal kind to preserve them from the furious winds from the Atlantic; as witness the fine specimens of *Dracena australis* on the outskirts of the bulb-field (fig. 131). The bulbs remain in the beds from two to six years, according as the variety propagates itself fast or slowly. During this period of time they receive annually, after the weeds and tops are mown off, a dressing of sea-weed, the easiest obtainable manure, and one exactly suitable to the needs and idiosyncrasies of the bulbs which are injured by contact with strong manures. On the better class of soils the handsome large-flowered varieties are cultivated; and on poorer soils, the Tazettas, Scilly White, Soleil d'Or, and Grand Monarque. Owing to this moderate manuring all the better-class varieties, which, in Holland, owing to the high feeding practised there, are fast dying out, in Scilly remain perfectly healthy.

PUBLICATIONS RECEIVED.—The "Gloucester" *Dirry and Directors' Calendar* for 1898. (Gloucester Railway Carriage & Wagon Co.) A useful and handy little volume, with directory for Gloucester visitors, general information, and ample space for daily notes. — *Cassell's Magazine*. The Christmas number is full, as usual, of letter-press of a seasonable character, plentifully interspersed with pictures, large and small. — *Nova Scotia Provincial Government Crop Reports*. The fruit crops are reported as far below the average; and as our own crops are also below the average, prices are likely to rule high. — *Forcing Tomatos*. New York Experiment Station. — *Westnik*. St. Petersburg. — *Les Phyllomes Hypopeltes*, par C. de Candolle. — *Jardin des Plantes de Montpellier*. Catalogue des graines recollées en 1897. — *Le Parc Public de l'Ezbekikh*, par G. Delchevalerie. — *Live Stock Journal Almanac*. — *Contributions from the Botanical Laboratory of the University of Pennsylvania*. — *Jaloo*. A lecture by Colonel Halford Thompson. — *The Plant World*. Nos. 1 and 2, edited by Dr. F. H. Knoulton. (Willard, Clute & Co., Binghampton.) — *The Weekly Florists' Review*. Chicago. — *The Australian Kitchen Garden*. (G Robertson, Melbourne, &c.) — *The Garden Annual* (37, Southampton Street, London) is in too general use to need recommendation.

HOME CORRESPONDENCE.

DUCHESS D'ANGOULÊME PEAR UPON A WALL.

—The remarkable experience given in your issue of Dec. 11 last concerning the above Pear as grown upon a wall seems to indicate that there is no complete connection between the treatment described and the splendid results obtained. If a tree is wanting in fruitfulness through sappy growth, root-pruning is advisable. The diminished growth of the following season, converted into fruit-spurs, will in the second year following the operation probably result in a crop. It would be interesting to know what kind of soil the tree was growing upon, also when it was planted in its present station, whether grafted on Quince or Pear, and what crops it has produced hitherto. Did it actually fail in fruitfulness owing to sappy growth? The question occurs whether root-pruning was done earlier than usual, which is after the end of October. Was it done in September, and the results accomplished within one year instead of two? But the application of lime may have produced the result if the soil was wanting in that constituent, as it would set free plant-food in the organic matter by assisting its decomposition. It might have the effect of sweetening the fruits themselves in the same way as applications of lime to meadows will cause destruction of harsh bitter grasses, and assist the growth of more nourishing and sweeter kinds. The particular variety of Pear is hardly one of merit as grown in this country, and in good fruit-shows it is usually conspicuous by its absence, or very moderately represented compared to other varieties, or to the splendid examples sent us annually from France. The crop described is thus even more remarkable, and also in contrast to the statement in the catalogues of the well-known Sawbridgeworth firm to the effect that this variety is usually insipid from a wall. The South Wales sea-coast, where the reported success occurred, doubtless resembles more the condition of France than this part of the kingdom. *H. H. R., Forest Hill.*

—My gardener has invited my attention to your interesting article on the Duchesse d'Angoulême Pear, which appeared in your issue of the 11th inst., by which it seems that the heaviest Pear of this variety, of which you have a note, weighed 1 lb. 10 oz. It will probably interest your readers to know that I gathered a Pear from a tree in my garden here—supplied by Messrs. Turner, and grown in my garden opposite their nursery—which weighed 1½ lb., although a small portion had been picked out by the birds. It was exhibited in a fruiterer's shop window here, and on November 6, 1895, when fully ripe, I had it weighed again and photographed, and found that it had lost 1½ oz., and then weighed 1 lb. 10½ oz. This fact of loss of weight in ripening may interest some of your readers. At the same time, on another of the trees of the same variety, viz., Williams' Duchesse d'Angoulême (or Pitmaston Duchess, as I believe it is also called), I had amongst several dozen Pears one fine group on one stem containing six fine Pears, touching each other, and weighing about 1 lb. each. I consider it one of the most handsome and luscious Pears grown. *R. H. Barrett, Slough.*

NATIONAL DAHLIA SOCIETY'S EXHIBITION.

As I am responsible for the erroneous statement, which appears on p. 439 of your last issue, that only "2,300 blooms" were staged at the last exhibition of the National Dahlia Society, allow me to explain how the error arose, and to give the correct number of flowers set up on that occasion. The above figures would be accurate enough but for the fact, which I omitted to take into account at the time, that in all but the classes set apart for Shows and Fancies the varieties are required to be staged in bunches. The correct totals for each section are as follows:—Shows and Fancies taken together, 1,530 blooms, Pompons 2,148, Cactus 1,926, singles 1,164, making a grand total of 6,768 blooms. This estimate does not include the many new Cactus Dahlias submitted for certificates, which were shown in bottles, or the large number of flowers used in the decorative arrangements set up in the commemoration class. Neither does it include the blooms in any of the non-competitive exhibits. I may here state that the exhibition was the largest ever held by the society. The shows and fancies taken together were more numerous than at any similar show for nine years, the Pompons than at any show since 1892, while the Cactus Dahlias were staged in greater numbers than at any preceding

National Dahlia Society's exhibition. *Edward Mawley, Berkhamsted.*

PRUNING APPLE AND PEAR TREES.—In the Hardy Fruit Calendar, p. 415, Mr. Ward gave directions how to prune Apples and Pears, and said "better let them go unpruned than trust an unskilful man with the pruning." He will pardon a small grower if I assert that a great many trees would be far more shapely and fruitful if they were not pruned at all during the first half-dozen years of growth, and after that time I am sure they will need but little. He further says: in the formation of large fruit-bearing trees, of whatever kind, in as short a time as possible, the young leading shoots should be pruned back from 5 to 9 inches, and each will produce three to five growths next season. Now if you have "cut back" either standards or bushes they will have at least nine to twelve growths, and if they are pruned back to 5 or 9 inches, and make three to five more growths, you will get from twenty-seven to sixty branches, within 5 to 9 inches of main stem, which in my humble opinion is far too many. I grant that the badly placed ones can be taken off, but the writer does not advise this, but to cut back to within 2 inches of last year's wood, which would cause still further growths and necessitate still more pruning. A standard-tree with six to eight growths to the main stem is in my opinion well provided, and though they may not appear many at the time, they will prove sufficient before twenty years have passed; and if these be left 18 to 24 inches long, instead of 5 to 9 inches, the sooner will you get a large tree, and fructification combined with a shapely specimen than is possible with so much pruning. I have yet to see a deciduous tree made shapely and fruitful by severe pruning. An Apple tree will make a handsome and fruitful specimen without the use of the knife at all. Even in this exposed place, the Blenheim Orange has fruited on an unpruned tree in the third year from budding; and a fan-shaped trained tree, five years old, has not shown a bloom. This year, Golden spire, only budded three years last June, produced a half-sieve of very fine fruits; the same tree last year yielded thirteen large fruits; while from five trees, but three years old, were taken 3½ sieves, which sold at half-a-crown per half-sieve. I also take exception to the pruning of laterals or growths other than leading ones back to "2 inches," as Mr. Ward advises. Two inches may be very well for trees whose growths are thin and spreading, such as Red Quarrenden, Adams' Pearmain, &c., but for rigid ones, as Blenheim, Betty Geeson, Dutch Codlin, Northern Greening, and Tower of Glamis, which are erect until fruit weighs them down, two inches would be too close to prune and expect fruit-buds to form as a result of the operation, unless the roots were curtailed at the same time—an operation entirely unnecessary so long as the tree has room to extend its branches. This is an old subject, but none the less an important one. *Jas. Kettle, Corfe Mullen, Wimborne.*

STANDARD ROSES.—In your issue for the 4th inst. there was a copy of an advertisement that reflected little credit on the paper it was taken from or upon the advertiser. I know of a man who in the spring advertises large bushy Fuchsias, 1s. 6d. per dozen, and these superior plants are sent to the purchaser in an ordinary night-light box. Annoying as such advertisements are to members of the trade who do not deal in rubbish, they are much less aggravating than the absurd recommendations of certain amateur gardening papers. An authority (?) advises as the very best standard Roses for a semi-circle facing windows the following mixture:—Persian Yellow, Marie Van Houtte, Chénédolle, Harrisoni, Madame A. Carrière, Celestial, Annie Alexieff, White Provence, Jules Margottin, Mdle. Nachury, Prefect Limbourg, Madame Perney, and Madame G. Luizet. Does the writer know a standard Rose when he sees it? *H. McDonald.*

ROSE CLOTH OF GOLD.—I can endorse all that your able writer "Wild Rose" says on p. 420 of the *Gardeners' Chronicle* for December 11, 1897, regarding the above Rose. In the summer of 1880, I was gardener at The Rectory, Farthinghoe, Northamptonshire, and on the gable-end of the house there was a large plant of this variety, some 80 or more feet in height. It had evidently been there many years, and the stem was large, and looked old. The aspect was south-west, and the soil a strong yellow loam. The blooms were so fine that I thought it the finest yellow Rose I had ever seen. I had not seen Rose

Cloth of Gold before, nor has it been my pleasure to see one since. *F. Southam, The Oaklands, Kenilworth Road, Leamington Spa.*

BULB AND POTATO-BOXES.—The box described by Mr. Burbridge on p. 422, seems to be the same as are the boxes I have had in use in Surrey for storing seed-Potatoes for the past three years. From a simple home-made pattern I gave to our county council carpenter, some 100 or more were made for my use; and whilst very strong, yet the entire cost for wood and labour was but about 6d. each. I should think these boxes, being strongly made, would last for twelve years at least. The ends are of ½-inch boards, 5 inches deep, and 13 inches long. The sides open an inch deep both top and bottom, are made of strips 3 inches deep of ½-inch board, and the bottoms are of the same material. The whole measurements are 15 inches long, and 13 inches wide; each box will comfortably hold 14 lb. of seed-tubers. There is a handle running along the centre on the top, a strip of wood one inch by five-eighths of an inch let into either end evenly. The raw edges of the handles are pared down, making them comfortable to handle. By having the sides partly open, should necessity compel the stacking of the boxes one on the other, air can, all the same, freely circulate amongst the tubers. As a dozen of these boxes may be stood one on the top of each other in case of need, or in hard weather, 12 pecks, or 3 bushels, of seed-tubers may be stored in a space such as is required for an ordinary chair. The boxes can be carried to the planting-ground and used as baskets most conveniently. I find it an excellent plan to write the name of the variety of Potato in the box on a small card, and tack it to the box. There is a small illustration of this simple and cheap Potato-box in my *Primer on Vegetable Culture*, published by Macmillan & Co. A. D.

A HALL FOR HORTICULTURE.—Mr. Cannell's letter on p. 436 of the *Gardeners' Chronicle* is the best that has appeared on this subject for a long time past, and there is a business ring about it. Cannot this subject be brought to a successful issue this time? It is a disgrace to horticulture in general—and especially so to London horticulture—that no better accommodation exists there for holding flower shows and meetings than the Drill Hall, James Street; surely the horticultural trade in and around London might sink all petty differences and unite for once on a subject like this and make the success of the venture certain. The trade especially, would reap very great advantages by having a suitable building, and it would only be fair that they should all assist with money as far as they are able to do so; and the advantages accruing to the various horticultural societies would likewise be inestimable. It is preposterous to say, as some have done lately, that the National Chrysanthemum Society could not succeed apart from its Music Hall associations. The Chrysanthemum has developed of late years into the most powerful attraction that we possess among flowers, and many persons travel long distances to see the National Show, and return home utterly disgusted with the disagreeable associations of the place it is held in, and of the difficulty experienced in an inspection of the exhibits. The fact that a comparatively young society like the Edinburgh can pay its expenses and give away £250 to charitable institutions, ought to set any doubts on this point at rest. It was a treat to visit such a show as this, at the Waverley Market, all the exhibits were displayed advantageously; and plenty of space allowed for the visitors to promenade round the tables and inspect the flowers and plants. Moreover, exhibitors were able to unload close to the tables on which the exhibits were displayed. The building was well lighted by electricity, the air was clear, the music discoursed by the band of the Grenadier Guards was of the best. Under such circumstances the pleasure of seeing the exhibits, and the beauty of the flowers is increased! and the visitors will have determined on attending the show another season. *W. H. Diers, Belvoir Castle Gardens, Grantham.*

—Mr. Henry Cannell, in writing to the *Gard. Chron.*, always means well, and I am in hearty sympathy with him in his desire to provide a home for horticulture, even if only large enough for routine business purposes. But a very important question is opened up when the proposal embraces space for the exhibitions of the special floricultural societies he names. I am afraid that Mr. Cannell and others who write in a similar strain, are utterly at sea as to the space required for the exhibitions of the National

Rose and National Dahlia Societies, which are much smaller than those of the National Chrysanthemum Society. There is no difficulty in finding ample space for the exhibitions of the other and smaller societies. I assisted in the arrangements of the first National Rose Show and the first National Dahlia Show, held in St. James' Hall, Regent Street, in 1858. The report of the former, written by the Rev. H. H. D'Ombra, which appeared in *The Florist* for August, 1858 stated, "We had heard much of the Hall itself, but as true florists let us confess we never bestowed a thought even upon it until the flowers had been thoroughly scanned, and then when we did look at it, we were disappointed. It was much smaller than we had imagined, and much too small for the purpose for which it was used on that day." It was

well a few figures be quoted. At the exhibition held at the Royal Aquarium on November 9, 10, 11, about 4,000 superficial feet of tabling was required to stage the exhibits, nearly three times the available space in the Drill Hall, James Street; and in addition about 2,000 feet of ground space was occupied; and this in association with broad gangways, and free access to all exits. Those who so freely criticise the breaking up of the display on the ground floor of the Aquarium, will now see that it is done largely in the interests of the public safety. Mr. Cannell's remarks about the disappointing amount of money the directors of the Royal Aquarium offer to the National Chrysanthemum Society are probably based upon some misleading figures recently given in the *Journal of Horticulture*.

over the average attendance which goes to make up a return for the outlay upon each of these three shows. *Richard Dean, Ealing, W.*

SUNSHINE.—The summer months of the Jubilee year were ever so much sunnier than the same months of any year during which sunshine has been registered. At Bradford we have not a fair share of sunshine, but such as we have is indicative of what occurs in other parts of the kingdom. The summer months include May, June, July, and August. During these months in 1887 we had 615 hours of bright sunshine, in 1897 we had 780 hours, whereas in 1896—nearly an average year—we had only 397 hours. The consequence of sunshine, I am persuaded, is very inadequately estimated. However, of one thing I am sure: the sunshine of last summer's months would feed up what without it would have been leaf-buds into blossom-buds. Therefore, as one consequence of the sunshine, next spring the trees and hedge-rows will be covered with bloom, and if the summer following be suitable, there will be plenty of berries for the birds in the winter of 1898-9, whether it be a hard winter or not. *John Clayton, December 18, 1897.*

FIG. 133.—LEAF OF PASSIFLORA ALATA.

PASSIFLORA ALATA.

I NOTICED in your report of the Royal Horticultural Society's show at the Crystal Palace, held on September 30 and two following days, that Mr. W. Tidy, gr. to W. K. D'Arcy, Esq., Stanmore Hall, included a dish of fruits of *Passiflora edulis* in the collection he exhibited on that occasion. As for many years the plant under the name at the head of this note has been grown and fruited at Bystock, I have wondered whether the *P. edulis* of Mr. Tidy and the *P. alata* are the same thing under different names. [They should be quite different. Ed.] Of the beauty and lusciousness of the *P. edulis* in question I can give no opinion, as I have not seen or tasted the identical fruit; but of *P. alata*, as grown here, I can speak in the highest terms. You have already figured a fruit in a number of the *Gardeners' Chronicle* for 1894 (fig. 135), whilst a reference to the plant and fruits appear in the number for Oct. 28, 1893, under the name of *P. quadrangularis*, which was that by which it was for a long time designated at Bystock.

I am pleased once again to call attention to this most excellent addition to the dessert-table, as well as to one of the most ornamental stove-climbers. At Bystock several fine plants are now planted out, two being in a fruiting Pine-stove, where they cover the roof-space over the path, and which this season produced over 200 fine fruits. The plants were out back early in the new year, when new growth quickly formed, and was fastened to the wires overhead. The growth is very rapid, and a fine show of flowers produced. Each bloom (fig. 134) was fertilised with a soft camel-hair brush, and the greater number set, and soon began to swell.

In midsummer the first fruit ripens, but growth still continues, and soon another large show of blooms appears; these are again fertilised, and the latter quantity of fruit usually exceeds, in large numbers, the first ripe ones. The plant was also grown in the Banana-houses, and here, too, we got fruit of superior size, but perhaps the number was not quite so great. This I attribute to the greater moisture of the Banana-houses, as many blooms fail to set, and soon drop off; but the Pine-stove, being naturally drier, the number of fruits failing to set and swell are comparatively few. This fruit was much esteemed, and I certainly think if it were better known, and the simple treatment given that it requires, it would be much more often met with, and would be found to be a very useful addition to the dessert. I may say, we have also the true *P. quadrangularis*, which I find less vigorous in growth, smaller in fruit, the colour of which is somewhat purple, while that of *P. alata* is of a tawny green. *W. Swan.* [Some fruits sent to us were made into a conserve of delicious flavour, richer, as far as we remember, than that of *P. quadrangularis* or *P. macrocarpa*, which are most undeservedly neglected. *P. edulis* is deliciously fragrant, but there is nothing to eat in it! Ed.]

so with the National Dahlia Show two months later: there was not nearly room enough to display the flowers to the best advantage. The very same disregard to the capacities of buildings confessed to above characterises many of the statements made by latter-day writers. I imagine the show of the National Rose Society in 1898 will be considerably larger than that held forty years before, and Mr. Cannell may learn from the foregoing something of the required size of a horticultural hall. Let it be remembered that in 1858 there was no London County Council taking precautions in the interests of the public safety, requiring to have deposited with them ground-plans showing commodious gangways, and clear passages to all exits. But the shows of the National Chrysanthemum Society! So many wild, speculative statements are made by, unreflecting writers as to the housing of these shows that it is

It is not necessary to go fully into such matters in this relation, so I content myself with the statement that the National Chrysanthemum Society is not called upon to expend anything upon tabling, staging, baize, &c., nor on advertising, with the exception of the leading gardening papers, nor on bill-printing or posting, nor on labour, except what is required during the show days; nor on lighting, cleaning up, or rent; nor have they to undergo expense on account of other items known only to those in close touch with flower shows; whilst music and entertainments are also provided free of charge. [! Ed.] If the National Chrysanthemum Society had to bear these expenses, and they could be totalled up into a lump sum, the amount would astonish. I have good reason to believe that the exhibitions held in September, October, and December bring but little to the exchequer of the Aquarium, it is only the increase

ORCHIDS, THEIR COLLECTING AND CULTURE.

(Paper read by John E. Lager, Summit, N.J., before New York Gardeners' Society, October 2, 1897.)

THE number of these plants has been greatly diminished the last few years, great quantities having been torn from their native homes and sent to various countries, but what has done more in South America to reduce their numbers, is the continually increasing plantations. Great zones of forests have been cut down lately, and extensive Coffee-plantations have taken their places. The *Cattleya* region has suffered the most, it being the right elevation and temperature for the Coffee-tree; but other Orchids have felt the change as well, such as the most useful *Odontoglossa*, &c.

Guided by the success I had on my first trip a few years ago, I last year made for the same old place, there only to find, not Orchids, but the forests gone, and Coffee-trees planted by the thousands. Orchid collecting being my sole object, I was greatly disappointed, but there was only one remedy, and that was to push further into uncivilised parts far from habitations; and I must say, I was fortunately rewarded by finding a most beautiful lot of *Cattleyas*, that, to judge by their appearance, had up to that date escaped the greed of the Orchid-hunter.

The South American Andes, as compared to other parts of the world, are, without the least doubt, the richest in useful species, as long as we keep to the Andes proper, which are marvellous in the number of species they contain. At almost every foot ascended from the foothills, new features of the vegetation are presented, one locality varying greatly from another. This variation ceases immediately at the foothills, below which extensive valleys and river-basins take the place of the rugged Cordilleras. The vegetation at these lower levels becomes at once more uniform, and plants found in the Magdalena and Cauca valleys of Colombia will, to the surprise of the traveller, appear repeatedly all through the Orinoco and Amazon valleys also. Some Orchids are also very erratic as to their abodes; *Miltonia vexillaria* appears in the State of Antioquia, Colombia, and then travels along the central Cordillera, a plant here and there, until all of a sudden we find it re-established in Ecuador and Peru. *Cattleya superba* is another appearing in spots in Colombia, Venezuela, and Brazil, and especially in the immense territories and low virgin forests embraced between the Orinoco, the Amazon, and Rio Negro systems.

Few people here imagine, when seeing beautiful Orchids in flower, how much trouble, work, and hardship have to be endured in securing them. Inconveniences of all descriptions are experienced at once upon setting foot on South American soil. [The illustration (fig. 132) shows that similar difficulties occur in the other hemisphere.] Here begins a series of the slow tedious transportations peculiar to these countries, ascending rivers sometimes by steamers, then by canoes, and traversing great stretches of land on mule and horseback, involving a lot of time and much expense before the longed-for Orchid region is reached. Yet there is always a certain charm attached to this mode of travelling. I enjoyed nothing more than to traverse one of the chains of the Cordilleras, starting out at three or four o'clock in early morning in the bright moonlight in order to avoid the heat of the valleys. Before the summit is reached the journey is hard, tiresome, and monotonous, and on roads and trails used by the Indians before the Spaniards, and which the latter used for three centuries without improvements or alteration. Leaving the tropical heat below, little by little the air gradually changes, becomes fresh and pure, and the rich aroma which the varied vegetation exhales is rapidly inhaled by the lungs in delicious draughts. At last the summit is reached; the road is less hard for man and beast, and finally a most beautiful and varied panorama is offered to our view of immense extensions of mountains rising one above the other, and in all possible shapes and angles, with deep declivities, narrow valleys, and roaring rivers. This beautiful scenery, recompenses the traveller for

the monotonous and tiresome ascent, and stimulates him on towards new expected triumphs in his explorations.

Many persons imagine Orchid gathering is an easy task, and they generally think that the plants grow on the trees by the ton, and consequently it is the easiest thing in the world to pull them off, put them in cases, and ship them home. On paper, and from a point of imagination, this is all very fine; but in reality such persons would find themselves greatly disappointed. To begin with, these plants never occur in quantities, even where most plentiful—only a few to a tree; while the greater part of the trees have none at all on them.

Material for packing-cases is another serious item to obtain—so serious, indeed, that often it is worse than getting the plants. Dry-goods boxes are often

many more, are principally what makes Orchid collecting both slow and expensive. Those huge snake and tiger stories of which, no doubt, you have heard, I have found in actual experience to be greatly exaggerated in connection with Orchid collecting. Some persons have asked me "Why don't you go down there and collect choice varieties only?" Yes, I should probably do so, were it only possible, but owing to the peculiar conditions of the country, it is utterly impracticable. Now and then a good thing is found, not always through the skill of the collector, but more through chance.

Supposing that *Cattleyas* are collected during their flowering season, owing to so many inconveniences, only a limited number of flowers is seen after they are gathered. A great number is torn off from the plants in felling the trees, and if a few are left, they

FIG. 134.—FLOWER OF PASSIFLORA ALATA. (SEE P. 449.)

bought long distances from the field of operations, taken apart, done up in bundles, and transported on mule-back to the place of packing. Sometimes this is impracticable, when other measures have to be resorted to, such as making crates out of Bamboo and stakes, &c. Frequently the plants have to be packed in bags, strapped on to the mules, and taken across narrow trails between rocks, stones and trees, wading rivers, &c., often to find the plants ground to pieces when the packing place is reached.

Another monstrous enemy will at times cross the collector's path in the shape of low water in the rivers. In this latter case he is left helpless until a freshet rushes down from the mountains. At the beginning of this year I came very near losing 100 cases of plants, already packed and piled up in tents on the river bank. For three long weeks I laid there impatiently waiting for a chance to move them. This, of course, is not the rule, but will happen when least expected. Difficulties of this nature, and

are liable to go also after carrying the plants in a bag for a few days. Then, in refusing plants out of flower, the men would soon refuse to collect, and without them the collector would have to leave the field without plants, probably a wiser man for the next trip.

Studying these plants in their native homes, the true conditions under which they grow, in order to derive some practical knowledge as to their culture, and lessen the sensational absurdities and mysteries in which this beautiful class of plants have been enshrouded until not very long back, we are gradually discovering the mysteries in their treatment, which, after all that has been said, written, and done, are only imaginary, and we can now note what a change has taken place the past few years in the cultivation of Orchids. The water-can, with its sometimes tepid water, has given way to the hose, and the clumsy blinds have been replaced by some simple form of white-wash. The material for potting or

GARDENERS' CHRONICLE

•

.

up is more sparingly used, and less labour is on its preparation. Air is admitted in larger ities, and the old system of closing up at a certain has outlived its usefulness. short, these

are now treated on a more common-sense These few things, simple as they may r at first sight, have been strong levers in g Orchids more popular in this country. *The ts' Exchange.*

THE NATIONAL AMATEUR GARDENERS' ASSOCIATION.

DECEMBER 16.—The annual dinner of this Association took place at the Holborn Restaurant on the above date, Mr. T. W. SANDERS, the President, occupying the chair, there being a large company, including many ladies.

In proposing "Success to the Association," the chairman stated that their Institution was a unique one, and it took charge of the interests of the *bond fide* amateur gardener, of which there were a large number about the country. He was proud to

MANCHESTER AND NORTH OF ENGLAND ORCHID.

DECEMBER 16.—The December meeting of the above Society was held in the Coal Exchange, Manchester, on the above date, the following members of the committee being present:—Messrs. W. Thompson, Chairman; G. Shorland-Ball, Vice-chairman; T. Statter, A. Warburton, J. Backhouse, G. W. Law-Schofield, H. Greenwood, D. B. Rappart, E. J. Sidebotham, R. Johnson, W. Stevens, H. Bolton, W. A. Gent (Hon. Sec.), J. Cypher, and P. Weathers. These meetings are evidently popular among the Orchidists, and no fewer than forty-two subjects were brought before the Committee.

Mr. H. WORTHINGTON, Abbey Lawn, Whalley Range, exhibited a very handsome form of *Laelia anceps* alba, reminding one much of the famous "Bull's alba," but with a more elongated lip (Award of Merit).

Mr. W. H. ALMOND, Alunscar, Blackburn, exhibited a very well grown plant of *Oncidium tigrinum* with a huge branched spike of blossom (Cultural Certificate).

Mr. J. CYPHER, Cheltenham, staged a variety of *Laelia tenebrosa* named *Thompsoni*, which had pale cinnamon sepals and petals, and pale rose-coloured labellum (Award of Merit); also a good form of *Cyp. Leeaanum giganteum* (Award of Merit).

Mr. W. THOMPSON, Walton Grange, Stone (gr., Mr. W. Stevens), staged a plant of *Laelia autumnalis* alba, of the purest white, with several flowers on the spike (Award of Merit); and a magnificent specimen of the beautiful *Laelia Gouldiana*, which is undoubtedly one of the finest in cultivation, having seven flower-spikes, all of which were well flowered. This was awarded a First-class Certificate and Cultural Certificate, a well deserved recognition.

Mr. H. BOLTON, Wilderspool, Warrington, exhibited a few interesting plants, amongst which was a very dark form of *Cattleya labiata autumnalis*, a very pretty form of *Odontoglossum Pescatorei*, well spotted with small violet markings, a very small form of *Cattleya Trianae* alba (the plant being weak), and an unusually late variety of *Cattleya Gaskelliana*.

Messrs. HUGH LOW & Co., Clapton, exhibited a superb form of *Cypripedium* \times *minos*, called *magnificum* (parents, *C. Spicerianum* \times *Arthurianum*).

Mr. J. LICHMANN, West Bank House, Hoaton-Mersey (gr., Mr. Edge), sent a few good things, including a well-flowered *Dendrobium superbiens*, *Cyp. Lathamianum*, a variety of *Cattleya labiata*, with lip very closely resembling *C. speciosissima*, a good form of *Cattleya Trianae* *delicata*, and an exceptionally good *C. Trianae*, "Fleur de Paradis," which obtained an Award of Merit. The same gentleman also exhibited *C. x Pitcherianum*.

Mr. G. SHORLAND-BALL, Wilmslow (gr., Mr. Hay), exhibited *Cypripedium insigne*, "Harefield Hall variety," a beautiful variety of exceptional size and substance (First-class Certificate); also a magnificent plant of *Cypripedium insigne* *Sandere* with three flowers (First-class Certificate); and *C. x Mrs. Maynard* (*nitens* \times *Leeaanum*), a distinct and useful plant (Award of Merit).

Mr. G. W. LAW-SCHOFIELD, Rawtenstall (gr., Mr. Schill), obtained an Award of Merit for *Cypripedium Leeaanum giganteum*; and a First-class Certificate for *C. x Cravenianum*, parentage not given, but possibly raised from *bellatulum* \times *Veitchi*, a very beautiful product, and gained a First-class Certificate.

Mr. O. O. WRIGLEY, Bury, exhibited *Cypripedium insigne*, "Uplands variety," which was almost identical with the "Harefield variety" (First-class Certificate). The same gentleman sent *C. Leeaanum perfectum* \times *C. Crossianum superbum*.

Mr. S. GRATRIX, Whalley Range, Manchester (gr., Mr. McLeod), exhibited *Cypripedium insigne* var. *Sanderianum*, a beautiful form, differing somewhat in shape from *Sandere*, and minus the few tiny spots which are peculiar to the latter variety (First-class Certificate). *C. Niobe* came from the same collection.

Mr. W. A. GENT, Brooklands, sent a form of *C. Lathamianum*.

Messrs. F. SANDER & Co. sent a few good things, *Odontoglossum cuspidatum* var. *magnificum* being a splendid variety to which an Award of Merit was given. *Laelio-Cattleya Gottleiana*, natural hybrid (*purpurata* \times *Warneri*) (Award of Merit). *O. crispum*, "Pink Beauty," a nice, well-formed flower suffused with a delicate blush (Award of Merit). The same firm sent the typical *O. Wattianum*.

Mr. H. GREENWOOD, Haslingden, staged a well-grown plant of *Laelia alba*, and that beautiful *Cypripedium* \times *Antigone* (*Lawenceanum* \times *niveum*); the flower was, however, somewhat small, or it possibly would have received the premier award (Award of Merit). *Dendrobium Kenneth* (*McCarthy* \times *Bensoniae*) came from the same collection.

Mr. E. J. SIDEBOTHAM, Bowden, showed a very beautiful and brilliant form of *Sophranitis grandiflora* (Award of Merit).

Mr. T. STATTER, Whitefield (gr., Mr. R. Johnson) exhibited *C. pripedium* \times *Statterianum*, a good thing with a richly coloured dorsal sepal (Award of Merit); *Cypripedium Leeaanum superbum* (Award of Merit); and a new albino form of *C. insigne*, very distinct, called "Johnsonianum" (Award of Merit).

Mr. E. BOSROCK, Tixall Lodge, Stafford, exhibited [a hybrid *Laelio-Cattleya*, and a pretty natural hybrid *Odontoglossum*. Mr. J. ROBSON, Altrincham, staged a pretty group of Orchids, amongst which were some good forms of *insigne* and various hybrid *Cypripediums* (Vote of Thanks).

Mr. R. OWEN, Northwich, also staged a group of the "mountain" forms of *C. insigne*, some really good things being amongst them (Vote of Thanks). P. W.

FIG. 135.—FRUIT OF PASSIFLORA ALATA. (SEE P. 449.)

SOCIETIES.

ANCIENT SOCIETY OF YORK FLORISTS.

MBER 15.—A company of between seventy and eighty men assembled at the annual dinner on the evening date, at the Bay Horse Hotel, Marygate, York, an Sir JOSEPH TERRY, J.P., President of the Society in the chair. The Society is in a flourishing condition, and consisted at the time of the late Chrysanthemum Show of 700 members, and since that date a considerable increase in the number of subscribers has taken

say that they had at the present time 600 members, of which number 100 had been added during the present year, while there were branches at Liverpool and elsewhere in a flourishing condition. He could honestly say there was an Institution to be proud of. He thought the Association could take credit to itself for the excellence of their quarterly Journal, of which their excellent Secretary, Mr. Leonard Brown, was the editor; and also in the fact that there was no Association in the country which could offer such advantages to their members as the National Amateur Gardeners' Association for such a small subscription as half-a-crown per annum. The toast was drunk with great enthusiasm; and during the evening various trophies, Challenge and other cups, Certificates, &c., were handed to their winners. Music and speeches carried on the proceedings until a late hour.

The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

DISTRICTS.	TEMPERATURE.				RAINFALL.		BRIGHT SUN.	
	ACCUMULATED.				Inch.	Ins.	Days.	Percentage of possible Duration for the Week.
	Above (+) or below (—) the Mean for the week ending December 18.	Above 42° for the Week.	Below 42° for the Week.	Above 42°, difference from Mean since January 3, 1897.				
0	3 +	12	26	+ 202	18	2	225	43.6
1	3 +	12	32	+ 41	5	1	197	28.5

11	5 +	62	0	+ 426	91	3	211	35.0

The districts indicated by number in the first column are the following:—

- 0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending December 18, is furnished from the Meteorological Office:—

"The weather continued unsettled and rainy during the greater part of the week, but towards the end it became quiet, foggy, and misty. The falls of rain were less heavy generally than those of the preceding week, but during the first day or two they were very considerable over the southern and south western parts of the Kingdom. Thunderstorms were experienced over all the southern counties of Ireland and England during the evening or night of the 14th.

"The temperature was rather low at the commencement of the period, but soon became very high for the time of year, so that the average for the week exceeded the normal by 3° in 'Scotland, N. and E.' and over Ireland, by 6° in 'England, E. and the Midland Counties,' and by 7° in 'England, S. and S.W.' Changes were, however, frequent and very sudden. The highest of the maxima were recorded on the 16th or 17th, when the thermometer rose to 58° over 'England, S.W. and N.W. and the Midland Counties,' and to between 55° and 57° over the other parts of the Kingdom. The lowest of the minima were registered, as a rule, either on the 12th or 13th, and varied from 17° in 'Scotland, E.' to 23° in 'Scotland, N.,' and to 30° in the 'Midland Counties and England, N.W.' In the Channel Islands, however, the lowest reading was 42°.

"The rainfall was rather less than the mean in Scotland, and just equal to it in 'England, N.E. and E.' and 'Ireland, N.' In all other districts there was an excess, that in the 'Midland Counties and England, S. and S.W.' being large.

"The bright sunshine exceeded the mean in all districts except 'England, N.E.' and 'Scotland, W.' The percentage of the possible duration ranged from 30 in the Channel Islands, and 27 in 'England, S. and S.W.' and 'Ireland, S.' to 10 in 'Scotland, W.' and 6 in 'England, N.E.'"

CATALOGUES RECEIVED.

 J. NURSERIES, Roupell Park, West Norwood, London, S.—Seeds, &c.

NOTICES TO CORRESPONDENTS.

BEST SIX AND TWELVE ROSES INTRODUCED SINCE 1896: *J. Miller*. A great authority on Roses says:—"It is too soon for any amateurs, I should think, to speak with confidence of the merits or demerits of Roses introduced since 1896. I would never give a character to a Rose without two years' personal trial at least, and should like more. Again: the system of cultivation pursued in your country under glass, treating the plants as annuals, worked maidens in pots, cutting the blooms, budding from the wood afresh, and then throwing away the plants every year, is one of which I have no experience. And as I have a strong opinion of the idiosyncrasies of Roses, of the different manners and customs of the several varieties under different modes of treatment, I could not say of any Rose for certain how it would answer under the American system."

BOOKS: *R. Miller*. Edwin Molyneux's work, *Chrysanthemums and their Culture*, is undoubtedly the best publication on the culture of this flower.—*The Book of the Rose*, by the Rev. Foster Melliar, will probably meet your wants. *Tree Fern*. A good work is Dr. Karl Schumann's illustrated *Monograph of Cactaceae, with Cultural Notes*, by M. Karl Hirscht. It is published in ten parts, by H. J. Neumann, of Neudamm, at 2s. per part. Obtainable through Messrs. Williams & Norgate, Henrietta Street, W.C.

CHRYSTANTHEMUMS FOR MARKET: *R. Miller*. The best six early-flowering varieties are Madame Desgranges, white; Mrs. Gifford, pink; M. Gustave Grunerwald, pink; G. Wermig, yellow; Source d'Or, bronze; Roi de Precoces, red. Six mid-season varieties, Elaine, white; Phobus, yellow; M. W. Holmes, rich crimson; Mrs. W. Filkins, golden yellow, thread petals; M. Freeman, pink; Annie Clibran, rose pink. The best six late-flowering varieties are L. Canning, white; W. H. Lincoln, yellow; Red L. Canning, red; Golden Gem, bronze crimson; Léon Frache, pink; M. E. A. Carrière, pink. The six best new varieties, Mrs. W. Mease, sport from Mme. Carnot, primrose; Mary Molyneux, rosy peach; Mrs. Ritson, white sport from Viviani Morel; Lady Hanham, golden, rosy-carise sport from Viviani Morel; Robert Powell, terra-cotta bronze; Julia Scaramanga, rich bronze terra-cotta.

CUCUMBER-HOUSE: *C. C.* Scour the woodwork with soap-suds, in which $\frac{1}{2}$ pint of petroleum may be mixed with every 3 gallons; or use Gishurst's soap and hot water, at the rate of 4 oz. of the former to 1 gallon of the latter. If fungus be present in the staging, you might destroy it by excessive drying, or the use of salt whilst the wood is damp. The better plan would be to throw it away.

CYPRIPEDIUM: *H. J. R. Florence*. Your suggestion that the two *Cypripediums* are between *C. villosum* and *C. Crossianum* is most likely correct, and the manner in which they vary seems to support the contention. The darker No. 1, seen by itself, would be taken for *C. pavoninum* (*C. villosum* × *C. venustum*); but the other is near to *C. Crossianum* (*C. insigne* × *C. venustum*). In one, the secondary cross is suppressed, and in the other developed. The *C. insigne* variety sent certainly is peculiar in the particulars you mention, but it is not a showy form.

FUNGUS IN MUSHROOM-BED: *McK.* The little white Agaric found on Mushroom beds is *Pleurotus mutilus*, which is always comparatively rare, and is usually found on the ground in grassy places. Probably the mycelium was introduced to the bed with the soil. It is perfectly harmless. *M. C. C.*

GRUBS ON CYCLAMENS: *G. H. S.* The grubs are those of one of the commoner and most destructive. Trap them with slices of Carrot laid about, and go round at night and capture them.

* LINDLEY LIBRARY.—We have received from "Alpha" the sum of 10s., to be devoted to the Catalogue Fund. We learn that the only copies of the Year Book or Horticultural Directory in the Library are those for 1870, '77, '84, '89, '90, and 1891. Readers having copies for which they have no further use might kindly send them to the Library, as they contain lists of plants introduced each year which will hereafter be valuable for reference. The Trustees will thankfully receive contributions of money or of books to increase the value of the Library and secure its proper maintenance.

NAMES OF FRUITS: *B. B., Exeter*. 1, Vicar of Winkfield; 2, Winter Nelis (?).—*J. B. Tibbette*. Probably, Apple Wareham Russet.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—*J. H.* 1, *Pinus excelsa*; 2, A golden variety of *Thuja occidentalis*; 3, *Picea pungens*, green variety; 4, *Picea polita*; 5, *Picea Morinda*; 6, *Retinospora plumosa aurea* of gardens, a stage of growth of *Cupressus pisifera*.—*H. E.* The seed-pods may, perhaps, belong to *Acacia riparia*; the other specimen is too scraggy for identification.—*P. C. P.* We regret the inadvertence. 1, Is probably an *Olearia*, send when in flower; 2, *Elæagnus pungens*.—*Ivy*: *T. N.* We are unable to name varieties of Ivy. Consult some nurseryman who makes a speciality of them.—*H. Y.* *Kuonymus europæus*, common Spindle-tree.—*J. P. K.* *Oncidium flexuosum*.—*W. P. N.* 1, *Adiantum Waltoni*; 2, *Davallia hirta cristata*; 3, *Pteris tremula*; 4, *Asplenium nidus* (Bird's-nest Fern); 5, *Pteris serrulata cristata*; 6, *P. serrulata*.—*J. W. McH.* A very finely coloured *Cattleya Loddigesii*.

PLANT ANALYSIS AND SOIL CONSTITUENTS: *D. P. C.* The preponderance of certain elements in the soil, as potash, sulphate of lime, carbonate of ditto, magnesia, oxide of iron, phosphoric acid, exert an undoubted influence on the growth, and consequently on the constituents of such plants as possess these substances in a marked degree in their leaves, stems, roots, flowers, or fruits. But then soils differ greatly, as, for instance, a peaty soil may contain 1.80 per cent. of carbonate of lime, whereas a chalky soil may contain as much as 28 per cent., and the organic matter in the former may equal 64, 66, and in the latter 3.13. We know of no book that would afford analyses of all kinds of garden plants.

RHODODENDRONS: *G. G.* There is no fungus visible; we have often seen similar appearances as a result of drought, and occasionally of lightning.

SLUGS: *J. S. Sulton*. *Testacella haliotides*, concerning which there has been much discussion in these pages during the past few weeks. In an early issue reference will be made to the subject, and illustrations given.

THE NATIONAL CHRYSTANTHEMUM SOCIETY: *X.* We cannot insert your letter, making such serious allegations, unless substantiated by something better than hear-say evidence.

THOMSON'S "GARDENERS' ASSISTANT": *C. O. L.* New edition not yet published.

WEIGHT OF A BUSHEL OF APPLES: *E. P.* The weight is between 40 and 45 lb. for home-grown fruits; Canadian and other foreign Apples are somewhat lighter.

WELLINGTONIA: *J. P.* The proper name is *Sequoia gigantea*, but for garden purposes you can use the commoner name. It was discovered in 1856 on the Pacific side of the Sierra Nevada in California, where it grows to a height of 250 to 327 feet. It was introduced here by William Lobb in 1853, and described by Lindley in these columns in the same year, p. 823. The largest tree recorded in the Report of the Conifer Conference (*Journal of Royal Horticultural Society*, vol. xiv., 1891), was one at Shanbally, co. Tipperary, which was then 80 feet in height. Several specimens were mentioned at that time as having reached 70 feet, among them that at Orton Longueville.

COMMUNICATIONS RECEIVED.—*J. A.*—*M. Schuster*.—*L. C.*—*P. W.* (with thanks).—*G. H.*—*C. T. D.*—*D. T. F.*—*Strathfieldsaye* (next week).—*W. P. N.* (next week).—*W. P. N.*—*J. W.*—*McH.*—*A. A. Chancellor*.—*R. W. G.*—*H. G. S.*—*F. W.*—*R. D.*—*W. K.*—*W. S.*—*J. R.*—*J. Lowrie*.—*H. M.*—*S. A.*—*J. Anderson*.—*E. C.*—*W. R.*—*R. H. P.*—*J. S.*—*C. W.*

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED, and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, and ALL CLASSES of GARDENERS and GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.
